which in abolishing the *ancien régime* fondly trusted that with it would go the duel, one of the privileges and abuses of an aristocratic society. Duplex in his *Military Law concerning the Duel* (1611), premises that these have no application to lawyers, merchants, financiers or justices. This explains why in the legislation of the National Assembly there is no mention of duels. Camille Desmoulins when challenged shrugged his shoulders and replied to the charge of cowardice that he would prove his courage on other fields than the Bois de Boulogne. The two great Frenchmen whose writings preluded the French Revolution both set their faces against it. Voltaire had indeed as a young man, in obedience to the dictates of society, once sought satisfaction from a noble man for a brutal insult, and had reflected on his temerity in the solitude of the Bastille. The story runs that Voltaire met the chevalier Rohan-Chabot at the house of the marquis of Sully. The chevalier, offended by Voltaire's free speech, insolently asked the marquis, "Who is that young man?" "One," replied Voltaire, "who if he does not parade a great name, honours that he bears." The chevalier said nothing at the time, but, seizing his opportunity, inveigled Voltaire into his coach, and had him beaten by six of his footmen. Voltaire set to work to learn fencing, and then sought the chevalier in the theatre, and publicly challenged him. A *bon mot* at the chevalier's expense was the only satisfaction that the philosopher could obtain. "Monsieur, si quelque affaire d'intérêt ne vous a point fait oublier l'outrage dont j'ai à me plaindre, j'espère que vous m'en rendrez raison." The chevalier was said to employ his capital in petty usury. After this incident and its consequences, Voltaire inveighed against duelling, not only for its absurdity, but also for its aristocratic exclusiveness. Rousseau had said of duelling, "It is not an institution of honour, but a horrible and barbarous custom, which a courageous man despises and a good man abhors." Napoleon was a sworn foe to it. "Bon duelliste mauvais soldat" is one of his best known sayings, and, when the king of Sweden sent him a challenge, he replied that he would order a fencing-master to attend him as plenipotentiary. After the battle of Waterloo duels such as Lever fives to depict were frequent between disbanded French officers and those of the allies in occupation. The restoration of the Bourbons brought with it a fresh crop of duels. Since then duels have been frequent in France—more frequent, however, in novels than in real life—fought mainly between politicians and journalists, and with rare exceptions bloodless affairs. If fought with pistols, the distance and the weapons chosen render a hit improbable, and, if fought with rapiers, honour is generally satisfied with the first blood drawn. Among Frenchmen famous in politics or letters who have "gone out" may be mentioned Armand Carrel, who fell in an encounter with Emile Girardin. Thiers, who thus atoned for a youthful indiscretion, the elder Dumas, Lamartine, Ste Beuve, who to show at once his sangfroid and his sense of humour, fought under an umbrella, Ledru Rollin, Edmond About, Clément Thomas, Veuillot, the representative of the church militant, Rochefort, and Boulanger, the Bonapartist *fanfaron*, whose discomfiture in a duel with Floquet resulted in a notable loss of popular respect.

Duels in England.—Duelling did not begin in England till some 100 years after it had arisen in France. There is no instance of a private duel fought in England before the 16th century, and they are rare before the reign of James I. A very fair notion of the comparative popularity of duelling, and of the feeling with which it was regarded at various periods, might be gathered by examining the part it plays in the novels and lighter literature of the times. The earliest duels we remember in fiction are that in the *Monastery* between Sir Pierce Shafton and Halbert Glyn, dining, and that in *Kerithworth* between Tressilian and Varney (That in *Anne of Geierstein* either is an anachronism or must reckon as a wager of battle.) Under James I we have the encounter between Nigel and Lord Dalgarno. The greater evil of war, as we observed in French history, expels the lesser, and the literature of the Commonwealth is in this respect a blank. With the Restoration there came a reaction against Puritan morality, and a return to the gallantry and loose manners of French society, which is best represented by the theatre of the day. The drama

of the Restoration abounds in duels. Passing on to the reign of Queen Anne, we find the subject frequently discussed in the *Tatler* and the *Spectator*, and Addison points in his happiest way the moral to a contemporary duel between Thornhill and Sir Cholmeley Dering. "I come not," says Spinemont to King Pharamond, "I come not to implore your pardon, I come to relate my sorrow, a sorrow too great for human life to support. Know that this morning I have killed in a duel the man whom of all men living I love best." No reader of *Esmond* can forget Thackeray's description of the doubly fatal duel between the duke of Hamilton and Lord Mohun, which is historical, or the no less life like though fictitious duel between Lord Mohun and Lord Castletown. The duel between the two brothers in Stevenson's *Master of Ballantrae* is one of the best conceived in fiction. Throughout the reigns of the Georges they are frequent. Richardson expresses his opinion on the subject in six voluminous letters to the *Literary Repostor* Sheridan, like Farquhar in a previous generation, not only dramatized a duel, but fought two himself. Byron thus commemorates the bloodless duel between Tom Moore and Lord Jeffrey —

Can none remember that eventful day,
That ever glorious almost fatal fray,
When Little's leadless pistols met the eyes,
And Bow Street myrmidons stood laughing by?

There are no duels in Miss Austen's novels, but in those of Miss Edgeworth, her contemporary, there are three or four. As we approach the 19th century they become rarer in fiction. Thackeray's novels, indeed, abound in duels. "His royal highness the late lamented commander-in-chief" had the greatest respect for Maj. Macmurdo, as a man who had conducted scores of affairs for his acquaintance with the greatest prudence and skill, and Rawdon Crawley's duelling pistols, "the same which I shot Captain Marker," have become a household word. Dickens, on the other hand, who depicts contemporary English life, and mostly in the middle classes, in all his numerous works has only three, and George Eliot never once refers to a duel. Tennyson, using a poet's privilege, laid the scene of a duel in the year of the Crimean War, but he echoes the spirit of the times when he stigmatizes "the Christless code that must have life for a blow." Browning, who delights in cases of conscience, has given admirably the double moral aspect of the duel in his two lyrics entitled "Before" and "After."

To pass from fiction to fact we will select the most memorable English duels of the last century and a half. Lord Byron killed Chaworth in 1765, Charles James Fox and Adams fought in 1779, duke of York and Colonel Lennox, 1789, William Pitt and George Tierney, 1796, George Canning and Lord Castlereagh, 1809, Christie killed John Scott, editor of the *London Magazine*, 1821, duke of Wellington and earl of Winchelsea, 1829, Roebuck and Black, editor of *Morning Chronicle*, 1835, Lord Alvanley and a son of Daniel O'Connell in the same year, Earl Cardigan wounded Captain Tuckett, was tried by his peers, and acquitted on a legal quibble, 1840.

The Killing of Captain Boyd — The year 1808 is memorable in the annals of duelling in England. Major Campbell was sentenced to death and executed for killing Capt. Boyd in a duel. In this case it is true that there was a suspicion of foul play, but in the case of Lieut. Blundell, who was killed in a duel in 1813, though all had been conducted with perfect fairness, the surviving principal and the seconds were all convicted of murder and sentenced to death, and although the royal pardon was obtained, they were all cashiered. The next important date is the year 1843, when public attention was painfully called to the subject by a duel in which Col. Fawcett was shot by his brother-in-law, Lieut. Monro. The survivor, whose career was thereby blasted, had, it was well known, gone out most reluctantly, in obedience to the then prevailing military code. A full account of the steps taken by the prince consort, and of the correspondence which passed between him and the duke of Wellington, will be found in the *Life of the Prince* by Sir T. Martin. Meanwhile there had been formed in London the association against duelling. It included leading members of both houses of parliament and distinguished

officers of both services. The first report, issued in 1844, gives a memorial of the association presented to Queen Victoria through Sir James Graham, and in a debate in the House of Commons (March 15, 1844) Sir H. Hardinge, the secretary of war, announced to the House that her majesty had expressed herself desirous of devising some expedient by which the barbarous practice of duelling should be as much as possible discouraged. In the same debate Turner reckoned the number of duels fought during the reign of George III. at 172, of which 91 had been attended with fatal results, yet in only two of these cases had the punishment of death been inflicted. But though the proposal of the prince consort to establish courts of honour met with no favour, yet it led to an important amendment of the articles of war (April, 1844). The 98th article ordains that "every person who shall fight or promote a duel, or take any steps thereto, or who shall not do his best to prevent duel, shall, if an officer, be cashiered, or suffer such other penalty as a general court martial may award." These articles, with a few verbal changes, were incorporated in the consolidated Army Act of 1879 (section 38), which is still in force.

Duels in Germany — Under the late imperial regime, German army duels were authorized by the military code as a last resort in grave cases. A German officer who was involved in a difficulty with another was bound to notify the circumstance to a council of honour at the latest as soon as he had either given or received a challenge. A council of honour consisted of three officers of different ranks and was instructed, if possible, to bring about a reconciliation. If unsuccessful the council had to see that the conditions of the duel were not out of proportion to the gravity of the quarrel.

Public opinion was greatly aroused by a tragic duel fought by two officers of the reserve in 1896, and the German emperor in a cabinet order of 1897, confirmed in 1901, enforced the regulation of the military court of honour, and gave warning that any infringement would be visited with full penalties of the law. It continued to be the fact that a German officer who was not prepared to accept a challenge and to fight, if the opinion of his regiment demanded it, was compelled to leave the service.

Under the Weimar republic prior to Hitler, the question was governed by articles 201 to 210 inclusive of the criminal code. The provisions referring to duelling may be summarized as follows:

- 1 (Article 201.) Any person challenging a second person to a duel or accepting such a challenge is liable to punishment by a term of imprisonment not exceeding six months.
- 2 (Article 205.) Persons taking part in a duel are liable to sentences ranging from three months to five years.
- 3 (Article 206.) Should anyone kill his opponent in a duel, he will be sentenced to imprisonment for not less than two years. Should it be shown, however, that the duel was entered into with mortal intent, the period of imprisonment shall not be less than three years.
- 4 (Article 210.) Should any person intentionally encourage another person to fight a duel, he will, in the event of the duel taking place, be punished by imprisonment for not less than three months.

The German Student Duels — The celebrated *Mensuren*, or German students' duels, survived World War I. They continued to form a regular element in German student life. In Berlin fighting corps met once a week in secret.

These meetings continued from 8 o'clock in the morning onward, with some 20 fights taking place on each occasion. The police, as well as the university authorities, presumably knew all about them, but were only too willing to close their eyes. These fighting corps or *Verbindungen* existed in every German university.

The entry of a student into one of these clubs was held to be a considerable honour, and was only possible where a student had shown the necessary qualifications to permit of his admission. It moreover carried with it a number of advantages to the student in after life, and very often helped him to obtain a good position in a profession or industry. The primary qualification would seem to be having fought three "parties" or matches

'successfully'

To fight a students' duel, it would seem that a considerable amount of previous practice was necessary. In each fighting *Verbindung*, a *Fechtsaal* formed part of the equipment of the club house, and duly practice was provided for fighting students under the supervision of the training instructor—one of the senior students of the *Verbindung* and named the *Zweiter Charakter*.

There were two categories of fighting students. First, the *Fuchs* or novice, second, the *Bursch* (fellow or accepted member), besides these, the "inactive," which means a student who had finished his time in the *Verbindung*, but still retained his membership of the university.

The training practice consisted of a number of short bouts fought under rather similar conditions to the actual duel. The student, however, was provided with a steel mist, to accustom him to the art of fencing without the possibility of damage. The body and arms were also protected. The sword, moreover, was not sharpened.

It is of interest in this connection to note that Roman Catholic members of the German universities were forbidden by their church to enter fighting *Verbindungen* on penalty of expulsion from the church.

Apparently the only point decided for or against a particular fighter was his bearing during the fight.

No points were given for skill in attack or defense and each fighter was judged by the witnessing *Korpsbrüder* of his own fighting *Verbindung* only.

Modern Views of the Duel.—Any formal discussion of the morality of duelling is, in England at least, happily superfluous. No fashionable vice has been so unanimously condemned both by moralists and divines. Some, however, of the problems, moral and social, which it suggests may be noticed briefly. That duelling flourished so long in England the law is, perhaps, as much to blame as society. It was doubtless from the fact that duels were at first a form of legal procedure that English law has refused to take cognizance of private duels. A duel in the eye of the law differs nothing from an ordinary murder. The greatest English legal authorities, from the time of Elizabeth downwards, such as Coke, Bacon and Hale, have all distinctly affirmed this interpretation of the law. But here as elsewhere the severity of the penalty defeated its own object. The public conscience revolted against a Draconian code which made no distinction between wilful murder and a deadly combat wherein each party consented to his own death or submitted to the risk of it. No jury could be found to convict when conviction involved in the same penalty a Fox or a Pitt or a Turpin or a Browning. Such, however, was the conservatism of English publicists that Bentham was the first to point out clearly this defect of the law, and propose a remedy. In his *Introduction to the Principles of Morals and Legislation*, published in 1789, Bentham discusses the subject with his usual boldness and logical precision. In his exposition of the absurdity of duelling considered as a branch of penal justice, and its inefficiency as a punishment, he only restates in a clearer form the arguments of Paley. So far there is nothing novel in his treatment of the subject. But he soon parts company with the Christian moralist, and proceeds to show that duelling does, however rudely and imperfectly, correct and repress a real social evil. "It entirely effaces a blot which an insult imprinths upon the honour. Vulgar moralists, by condemning public opinion upon this point, only confirm the fact." He then points out the true remedy for the evil. It is to extend the same legal protection to offences against honour as to offences against the person. The legal satisfactions which he suggests are some of them extremely grotesque. Thus for an insult to a woman, the man is to be dressed in woman's clothes, and the retort to be inflicted by the hand of a woman. But the principle indicated is a sound one, that in offences against honour the punishment must be analogous to the injury. Doubtless, if Bentham were now alive, he would allow that the necessity for such a scheme of legislation had in a great measure passed away. That duels have since become extinct is no doubt principally

owing to social changes, but it may be in part ascribed to improvements in legal remedies in the sense which Bentham indicated. A notable instance is Lord Campbell's Act of 1843, by which, in the case of a newspaper libel, a public apology coupled with a pecuniary payment is allowed to bar a plea. In the Indian code there are special enactments concerning duelling, which is punishable not as murder but as homicide.

The duel, which in a barbarous age may be excused as "a sort of wild justice," was condemned by Bacon as "a direct affront of law and tending to the dissolution of magistracy." It survived in more civilized times as a class distinction and as an ultimate court of appeal to punish violations of the social code. In a democratic age and under a settled government it is doomed to extinction. The military duels of the European continent, and the so-called American duel, where the lot decides which of the two parties shall end his life, are singular survivals. For real offences against reputation law will provide a sufficient remedy. The learned professions will have each its own tribunal to which its members are amenable. Social stigma is at once a surer and juster defence against conduct unworthy of a gentleman.

DUENNA, specifically the chief lady in-waiting upon the queen of Spain (Span *duena*, a married lady or mistress, Lat *domina*). The word is more widely applied, however, to an elderly lady in Spanish and Portuguese households (holding a position midway between a governess and companion) appointed to take charge of the young girls of the family, and "duenna" is thus used in English as a synonym for chaperon (*q v*).

DUEPPEL, a village of Germany, in the Prussian province of Schleswig Holstein, opposite the town of Sonderburg (on the island of Alsen) (Pop 600). The position of Düppel, forming as it does a bridge head for the defenders of the island of Alsen, played a conspicuous part in the wars between Denmark and the Germans. On May 28, 1848, the German federal troops were there defeated by the Danes under Gen. Hedebrand, and a second battle was fought on June 6, 1848. On April 13, 1849, an indecisive battle was fought between the federal troops under Prittwitz and the Danes under Bulow. The most important event in the military history of Düppel was, however, the siege by the Prussians of the Danish positions in 1864. The flanks of the defenders' line rested upon the Alsen sund and the sea, and a second line of trenches was constructed behind the front attacked, and a small redut opposite Sonderburg to cover the bridges between Alsen and the mainland. The Prussian siege corps was commanded by Prince Frederick Charles and after three weeks' skirmishing a regular siege was begun, the batteries being opened on March 15. The siege was pushed rapidly from the first parallel, completed March 30, and the assault delivered on April 18. The whole line was carried after a brief but severe conflict, and the Prussians had penetrated to and captured the redut opposite Sonderburg by 2 P.M. The loss of the Danes, half of whose forces were not engaged, included 1,800 killed and wounded and 3,400 prisoners. This operation was followed by the daring passage of the Alsen sund, effected by the Prussians in boats almost under the guns of the Danish warships, and resulting in the capture of the whole island of Alsen (June 29, 1864).

See R. Neumann, *Über den Angriff der Doppelten Schanzen in der Zeit vom 15. März bis 18. April 1864* (1865), and *Der deutschdänische Krieg 1864* published by the Preussien General Staff (1887)

DUET, a term in music for a composition for two performers, either vocal or instrumental, in which the two parts are of more or less equal importance. Thus a piece for a violin and piano in which the latter provides merely an accompaniment is not properly called a duet. Duo is a term having the same meaning though usually applied to instrumental duets only.

DUFAURE, JULES ARMAND STANISLAS (1798-1881), French statesman was born at Saujon (Charente Inferieure) on Dec. 4, 1798. He became an advocate at Bordeaux, and in 1834 was elected deputy. As minister of public works (1839) in the Soult ministry, he freed railway construction in France from the obstacles which till then had hampered it. In 1840 Dufaure became one of the leaders of the Opposition, and on the outbreak of the revolution of 1848 he frankly accepted the Republic. On Oct. 13 he became minister of the interior under G. Cavaignac but retired on the latter's defeat in the presidential election. During the Second Empire Dufaure practised at the Paris bar and was elected *batonnier* in 1862. In 1863 he succeeded to Pasquier's seat in the French Academy. In 1871 he became a member of the Assembly, and it was on his motion that Thiers was elected President of the Republic. Dufaure was minister of justice under Thiers and under L. J. Buffet, whom he succeeded (March 9, 1876) as president of the council. He resigned office on Dec. 12 but returned to power on Dec. 24, 1877. Early in 1879 Dufaure took part in compelling the resignation of Marshal MacMahon, but immediately afterwards (Feb. 1), worn out by opposition, he himself retired. He died in Paris on June 28, 1881.

See G. Picot, *M. Dufaure, sa vie et ses discours* (1883).

DUFF, ALEXANDER (1806-1878), Scottish missionary in India, was born at Auchnahyle, Moulton, Perthshire. At St. Andrews university he came under the influence of Dr. Chalmers, and was sent out by the foreign mission committee of the general assembly as their first missionary to India. He was ordained in Aug. 1829, and started at once for India, but was twice shipwrecked before he reached Calcutta in May 1830, and lost all his books and other property. Up to this time Protestant missions in India had been successful only in reaching low caste and out-caste peoples, particularly in Tinnevely and south Travancore. The Hindu and Mohammodan communities had been practically untouched. Duff therefore devised the policy of an educational mission. He first opened an English school in which the Bible was the centre of the school work, and along with it all kinds of secular knowledge were taught from the rudiments upwards to a university standard. The school soon began to expand into a missionary college, and a Government minute was adopted on March 7, 1835, to the effect that in higher education the object of the British Government should be the promotion of European science and literature among the natives of India.

After six years' furlough in England, Duff returned in 1840 to India. In 1839 the earl of Auckland, governor general, had yielded to the "Orientalists" who opposed Duff, and adopted a policy which was a compromise between the two. At the Disruption of 1843 Duff sided with the Free Church, gave up the college buildings with all their effects, and with unabated courage set to work to provide a new institution. He had the support of Sir James Outram and Sir Henry Lawrence, and the encouragement of seeing a new band of converts, including several young men of high caste. In 1844 Viscount Hardinge opened Government appointments to all who had studied in institutions similar to Duff's Foundation. In the same year Duff took part in founding the *Calcutta Review*, of which from 1845 to 1849 he was editor. In 1849 he returned home. He was moderator of the Free Church assembly in 1851.

In 1856 Duff returned to India. He gave much thought and time to the University of Calcutta, which owes its examination system and the prominence given to physical sciences to his influence. In 1863 Sir Charles Trevelyan offered him the post of vice-chancellor of the university, but his health compelled him to leave India. He continued his work for foreign missions in

different parts of the world, and was the first occupant of the chair of foreign missions at New College, Edinburgh, and at his death, on Feb. 12, 1878, left his personal property to found a lectureship on foreign missions on the model of the Bampton lectures.

See his *Life*, by George Smith (2 vols.)

DUFF, SIR EVELYN MOUNTSTUART GRANT (1863-1926), British diplomatist, second son of the Sir Mount Stuart Grant Duff, the administrator and diarist, was born on Oct. 9, 1863. From 1888 he was on Foreign Office service in Rome, Tehran, St. Petersburg (Leningrad), Stockholm and elsewhere. In 1913 he was made minister at Bern, a post which acquired great importance with the outbreak of war in 1914. Grant Duff had the responsibility of furthering friendly relations between the British and Swiss Governments and of mitigating the difficulties arising out of the blockade. He was the object of a violent news paper campaign instigated by the Germans, and was accused of taking observations of Friedrichshafen from the neutral Roman shore. This propaganda was officially contradicted by the Swiss Government. In 1900 he married Edith Florence, daughter of Sir George Bonham. Lady Grant Duff gave invaluable assistance in organizing the *Bureau de Secours aux prisonniers de Guerre* (British Section). Sir Evelyn resigned in August 1916. He died at Bath on Sept. 19, 1926.

DUFF, SIR MOUNTSTUART ELPHINSTONE GRANT (1820-1906), British politician and writer, was born at Eden, Scotland. He was educated at Edinburgh and Oxford, and in 1854 was called to the bar. He sat in parliament as the Liberal member for the Elgin Burghs from 1857 to 1881, being under secretary of state for India from 1868 to 1874 and for the colonies during 1880-81. He was governor of Madras from 1881 to 1886. His writings include *Miscellaneous, Political and Literary* (1878), *Studies in European Politics* (1886), *Memoirs of Henry Mann* (1892), *Reminiscences* (1893), and *Notes from a Diary for the years 1851-1901* (14 vols., 1897-1905).

DUFFERIN AND AVA, FREDERICK TEMPLE HAMILTON-TEMPLE-BLACKWOOD, 1ST MARQUESS OF (1826-1902), British diplomatist, son of Price Blackwood, 4th Baron Dufferin, was born at Florence, Italy, on June 21, 1826. The Irish Blackwoods were of old Scottish stock, tracing their descent back to the 14th century. Frederick went to Eton (1839-43) and Christ Church, Oxford (1845-47), where he took a pass school and was president of the Union. His father died in 1841, and the influence of his mother, Helena Selma Sheridan—one of three unusually accomplished sisters, the other two being the duchess of Somerset and Mrs. Norton (*q.v.*)—was very marked on his mental development, she lived till 1867 and is commemorated by the "Helen's Tower" erected by her son in her honour at Clondeboyne (the Irish seat of the Blackwoods) in 1861, and adorned with epigraphical verses written by Tennyson, Browning and others. Her son edited her *Poems and Verses* (1894). In 1846-48 Lord Dufferin was active in relieving the distress in Ireland due to the famine. He was a good landlord, in 1855 he already advocated compensation for disturbance and for improvements, but while supporting reasonable reform, he demanded justice for the landowners. When Gladstone adopted Home Rule, Lord Dufferin regarded the new policy as fatal both to Ireland and to the United Kingdom, though, being then an ambassador, he took no public part in opposing it. In 1849 Dufferin was made a lord in waiting. In 1855 Lord John Russell took him as attaché on his special mission to the Vienna Conference, and in 1860 sent him as British representative on a joint commission of the powers appointed to inquire into the affairs of the Lebanon (Syria), where the massacres of Christian Maronites by the Mussulman Druses had resulted in the landing of a French force and the possibility of a French occupation. Lord Dufferin was associated with French, Russian, Prussian and Turkish colleagues, and the diplomatic position was delicate. At last it was agreed to place a Christian governor, subordinate to the Porte, over the Lebanon district, and to set up local administrative councils. In May 1861 the French forces departed, and Lord Dufferin was thanked for his services by the government. In 1862 he married Harriet, daughter of Cap-

tain A. Rowan Hamilton, of Killyleagh Castle Down. He held successively the posts of under secretary for India (1864-66) and under secretary for war (1866) in Lord Palmerston's and Earl Russell's ministries, and he was chancellor of the duchy of Lancaster, outside the cabinet, under Gladstone (1868-72). In 1871 he was created earl of Duffern.

In 1872 he was appointed governor general of Canada. He had already become known as a powerful and graceful orator, and a man of culture and political distinction, and his abilities were brilliantly displayed in dealing with the problems of the newly united province of the Canadian Dominion. He admirably strengthened and consolidated the imperial connection. Lord Duffern left Canada in 1878, and in 1879 he was appointed by Lord Beaconsfield ambassador to Russia. In 1881 he was transferred to Constantinople, where he was concerned in the negotiations connected with the situation in Egypt caused by Arab revolt and the intervention of Great Britain. He was considerably helped by Turkish ineptitude, and by the accomplished fact of British military successes in Egypt, but his own diplomacy contributed to secure freedom of action for Great Britain. From Oct. 1882 to May 1883 he was in Egypt as British commissioner to report on a scheme of reorganization. In 1884 he was appointed viceroy of India, succeeding Lord Ripon. Lord Duffern though agreeing in the main with Lord Ripon's native policy, gained the confidence of the Anglo-Indian community without producing any undesirable reaction. He initiated stable relations with Afghanistan, and settled the crisis with Russia arising out of the Panjdeh incident (1885), which led to the delimitation of the north-west frontier (1887). The annexation of Burma during his viceroyalty procured for him, on his resignation, the title of marquis of Duffern and Ava (1888). His viceroyalty was also memorable for Lady Duffern's work in providing better medical treatment for native women. In 1888 he was made ambassador at Rome, and in 1892 ambassador in Paris. He retired in 1896.

His last years, spent mainly at his Irish home, were clouded by the death of his eldest son, the earl of Ava, at Lydsmith in the Boer War (1900), and by business troubles due to his having accepted the chairmanship of the London and Globe Finance Corporation, of which Whitaker Wright was managing director. He died on Feb. 12, 1907, and was succeeded in the title by his second son Terence (1866-1918). His fourth son Frederick (b. 1875) succeeded in 1918 and was Speaker of the Senate, Northern Ireland, in 1921. Killed in an air crash, July 21, 1930, he was succeeded by his son Basil, Lord Ava (1900-1945).

BIBLIOGRAPHY—Lord Duffern's *Letters from High Latitudes*, an account of a voyage to Iceland, was published in 1857 and has been re-issued in the Iversman's Library (1910). His *Speeches and Addresses* have been edited by H. Milton (1882). The official *Life of Lord Duffern*, by Sir Alfred Lyall, appeared in 1905. There are two Canadian histories of his Canadian administration, one by George Stewart (1878), the other by W. Leggo (1878). Lady Duffern wrote *My Viceroyalty in India* (1889), and *My Canadian Journal* (1891). Sir Spencer Walpole, *Studies in Biography* (1907). Sir Arthur Comyn Lyall, *The Life of the Marquis of Duffern and Ava*, 2 vols. (1925).

DUFF-GORDON, LUCIE (1821-1860), English woman of letters, daughter of John and Sarah Austin (q.v.), was born on June 24, 1821, and died in Egypt on July 14, 1860. Her chief playfellows as a child were her cousin, Henry Reeve, and John Stuart Mill, who lived next door in Queen Square, London. In 1834 the Austins went to Boulogne, and at table d'hôte Lucie found herself next to Heinrich Heine. The poet and the little girl became fast friends, and years afterwards she contributed to Lord Houghton's *Monographs Personal and Social* a touching account of a renewal of their friendship when Heine lay dying in Paris. Her parents went to Malta in 1836, and Lucie Austin was left in England at school. She married in 1840 Sir Alexander Duff Gordon (1811-1871). With her mother's beauty and her father's her social gifts, and she gathered round her a brilliant circle of friends. George Meredith has analysed and described her extraordinary success as a hostess and the process by which she reduced too ardent admirers to 'happy crust-munching devotees.' 'In England in her day,' he says, 'while she sat with her three or four house where men and women conversed when that house perfume was closed a

light had gone out in our country.' She went in 1860 to the Cape of Good Hope, and later to Egypt, where she died. She had translated among other works *Ancient Grecian Mythology* (1830) from the German of Niebuhr, *Mary Schuadler, The Amber Witch* (1844) from the German of Wilhelm Meinhold, and *Stella and Vanessa* (1850) from the French of A. F. L. de Wailly. Her *Letters from the Cape* (1862-63) appeared in 1865, and were reprinted in 1927, and in 1865 her *Letters from Egypt*, edited by her mother, attracted much attention. *Last Letters from Egypt* (1875) contained a memoir by her daughter, Janet Ross (q.v.). Lady Duff Gordon won the hearts of her Arab dependents and neighbours. She doctored their sick and taught their children.

The *Letters from Egypt* were not originally published in a complete form. A fuller edition with an introduction by George Meredith was edited in 1902 by Mrs. Janet Ross. See also Mrs. Ross's *Three Generations of Englishwomen* (1886).

DUFFTOWN, small burgh, Banffshire, Scotland, on the Fiddich, 64 m. WNW of Aberdeen by the LNER. Pop. (est. 1938) 1,429. It dates from 1817 and bears the name of its founder, James Duff, 4th earl of Fife. Although planned in the shape of a cross, with a square and tower in the middle, the arms of the cross are not straight, the constructor holding that, in order to prevent little towns from being taken in at a glance, their streets should be crooked. The leading factories are lime works and distilleries, the water being good for whisky making. The town is a health resort. Dufftown is in the parish of Mortlach. The Stone of Mortlach is traditionally believed to have been erected to commemorate the success of Malcolm II. over the Danes in 1010. There are also three large stones known as 'The King's Grave,' a hill fort and Cairns. A portion of old Balvenie castle, a ruin, is considered to be of Pictish origin, but most of it is of the Scots Baronial period. Two miles south east of Dufftown is the ruined castle of Auchindown, on a limestone crag, 200 ft. high, of which three sides are washed by the Fiddich and the fourth was protected by a moat. It dates from the 11th century, and once belonged to the Ogilvies, from whom it passed in 1535 to the Gordons. The Gothic hall with rows of fluted pillars is in fair preservation. About 4 m. to the NW is Cragellachie, on the confines of Elginshire. It is a growing place, with a large hotel, situated on the Spey amidst fine scenery. The slogan of the Grants is 'Stand fast Cragellachie!'

DUFFY, SIR CHARLES GAVAN (1816-1903), Irish and colonial politician, was born in Monaghan, Ireland, on April 12, 1816. He was one of the founders (1842) of the *Nation*, a Dublin weekly remarkable for the fire and spirit of its political poetry. In 1844 Duffy was included in the same indictment with O'Connell, and shared his conviction in Dublin and his acquittal by the House of Lords upon a point of law. His ideas, nevertheless, were too revolutionary for O'Connell, a schism took place in 1846, and Duffy united himself to the 'Young Ireland' party. He was tried for treason felony in 1848, but the jury were unable to agree. Duffy continued to agitate in the press and in parliament, to which he was elected in 1852, but his failure to bring about an alliance between Catholics and Protestants upon the land question determined him in 1856 to emigrate to Victoria. There he became in 1857 minister of public works, and after an active political career, in the course of which he was prime minister from 1871 to 1873, when he was knighted, he was elected speaker of the House of Assembly in 1877, being made K.C.M.G. in the same year. In 1880 he resigned and returned to Europe, residing mostly in the south of France. He published *The Ballad Poetry of Ireland* (1845), several works on Irish history, *Conversations with Carlyle* (1892), *Memoirs* (1898), etc. In 1891 he became first president of the Irish Literary Society. He died on Feb. 9, 1903.

DUFOUR, WILHELM HEINRICH (GUILLAUME HENRI) (1787-1875), Swiss general, was born at Constance, of Genevese parents temporarily in exile, on Sept. 15, 1787. He studied at the École Polytechnique in Paris, served in the French army, and returned to Switzerland after 1815. He became chief instructor at the military school at Thun, where he had Louis Napoleon (Napoleon III.) among his pupils. He earned out the trigonometrical survey of Switzerland, which was thirty-two years in the

making In 1847 Dutour was made general of the Federal Army, which was employed in reducing the revolted Catholic cantons a task in which he showed conspicuous skill and moderation In politics he belonged to the moderate conservative party, and he consequently lost a good deal of his popularity in 1848 In 1856, in the conflict with Frederick-William IV of Prussia over the possession of Neuchâtel, Dufour was put at the head of the republican army and was sent to Paris to obtain the mediation of Napoleon III, and again in 1859 at the time of the French annexation of Savoy, he was in charge of the negotiations at Paris concerning the neutrality of northern Savoy (See SWITZERLAND History) In 1864 he presided over the international conference which framed the Geneva Convention as to the treatment of the wounded in time of war, etc He died on July 14, 1875

His works include *De la fortification permanente* (1850), *Mémoire sur l'artillerie des anciens et sur celle du moyen âge* (1840), *Manuel de tactique pour les officiers de toutes armes* (1842), and various other works in military science His memoir, *La Campagne du Sonderbund* (Paris, 1876), is prefaced by a biographical notice

See Sun-Bardiene, *Das Buch des Generals Dufour* (6th ed, 1897)

DUGDALE, SIR WILLIAM (1605-1686), English antiquary, was born at Shustoke, near Coleshill, Warwickshire, on Sept. 12, 1605 He married at 17, and lived with his wife's family until his father's death in 1621, when he went to live at Tillingley, near Shustoke, an estate formerly acquired for him by his father In 1625 he purchased the manor of Blythe, Shustoke, and removed thither in 1626 In 1635 he met Sir Symon Archer (1581-1662), himself a learned antiquary, who was then employed in collecting materials for a history of Warwickshire, and accompanied him to London In 1638 Dugdale was created a pursuivant of arms extraordinary by the name of Blanch Lyon, and in 1639 rouge croix pursuivant in ordinary He now had a lodging in the Herald's Office, and spent much of his time in London examining the records in the Tower and the Cottonian and other collections of MSS In 1641 Sir Christopher Hatton, foreseeing the war and dreading the ruin and spoliation of the church, commissioned him to make exact drafts of all the monuments in Westminster Abbey and the principal churches in England, including Peterborough, Ely, Norwich, Lincoln, Newark, Beverley, Southwell, Kingston-upon-Hull, York, Selby, Chester, Lichfield, Tamworth and Warwick In June 1642 he was summoned to attend the king at York. When war broke out Charles deputed him to summon to surrender the castles of Banbury and Warwick, and other strongholds which were being rapidly filled with ammunition and rebels He went with Charles to Oxford, remaining there till its surrender in 1646 He witnessed the battle of Edgehill, where he afterwards made an exact survey of the field, noting how the armies were drawn up, and where and in what direction the various movements took place, and marking the graves of the slain In Nov. 1642 he was admitted M.A. of Oxford university and in 1644 the king created him Chester herald During his leisure at Oxford he collected material at the Bodleian and college libraries for his books In 1646 Dugdale returned to London and compounded for his estates, which had been sequestrated, by a payment of £168 After a visit to France in 1648 he continued his antiquarian researches in London, collaborating with Roger Dodsworth (q.v.) in his *Monasticon Anglicanum*, which was published successively in single volumes in 1655, 1661 and 1673 At the Restoration he obtained the office of Norroy king-at-arms and in 1677 was created baronet principal king-at-arms and was knighted He died at Blythe hall on Feb. 10, 1686

Dugdale's most important works are *Antiquities of Warwickshire* (1656, 1786), *Monasticon Anglicanum* (1655-73, 1840), *History of St. Paul's Cathedral* (1658), and *Baronage of England* (1675-76) His *Life*, written by himself up to 1678, with his diary and correspondence, and an index to his manuscript collections, was edited by William Hamper, and published in 1827

DUGONG, one of the two existing genera of the Sirenia, or herbivorous aquatic mammals Dugongs (*Dugong*) are distinguished from manatee by the presence in the upper jaw of the male of a pair of large tusks There are never more than six molar teeth on each side of either jaw, and these are flat on

the grinding surface The flippers are unprovided with nails, and the tail is broad and crescent-shaped, the bones are hard and firm

Dugongs frequent the shallow waters of tropical seas where they may be seen basking on the surface of the water, or browsing on submarine pastures of seaweed, for which the thick lips and truncated snout pre-eminently fit them, they are gregarious The female produces a single young one at a birth, and is remarkable for its great maternal affection

One species, with possibly several races, is known as *Dugong dugong* This is distributed in the Red sea, the Indian ocean and east in the Pacific as far as the Solomon and Marshall Islands, it ranges south along the coast of northern Queensland, Australia

DUGONG (DUGONG DUGONG)

and north as far as the Lau Kiu Islands between Formosa and Japan The islanders frequently hunt it with spears, for its flesh is an esteemed delicacy The oil obtained from its blubber has been of commercial value and a full grown dugong may yield from 10 to 12 gallons Adult animals are from 7 to 9 ft in length

DUG-OUT, an underground chamber or passage dug out of a slope or bank or in a trench The simplest form of dug-out is the small shelter for two or three men, protecting them rather against the elements than against the effects of enemy fire, larger and more elaborate dug outs will secure their occupants against bullets and splinters of shell, while the deep mined works, constructed by all belligerents on the Western front during the World War, were capable of housing whole units in complete immunity from even the heaviest bombardment, and were in many cases equipped with lighting, sleeping and living facilities As against this security from shell fire, however, it was found that these large dug-outs often proved traps for the garrisons sheltering in them, who were unable to emerge in time to repel a hostile infantry attack, and during the later years of the war their construction was largely discontinued The word also designates the Western plain dwellings of North American pioneers (See also CANOE)

DUGUAY-TROUIN, RENÉ (1673-1735), French sea captain, was born at St. Malo on June 10, 1673 On the outbreak of the war with England and Holland in 1689 he went to sea in a privateer owned by his family As a volunteer in a vessel of 28 guns he was present in 1690 at a bloody combat with an English fleet of five merchant vessels His family then gave him a corsair of 14 guns, and having been cast by a storm on the coast of Ireland, he burned two English ships in the River Limerick In 1694 his vessel of 40 guns was captured by the English and he was confined in the castle of Plymouth He escaped and obtained command of a vessel of 48 guns and captured some English vessels on the Irish coast In 1696 he made a brilliant capture of Dutch vessels and was made *capitaine de frégate* (commander) in the royal navy In 1704-5 he persistently raided the coasts of England In 1706 he was raised to the rank of captain of a vessel of the line In 1707 he captured off the Lizard the greater part of an English convoy of troops and munitions bound for Portugal His most glorious action was the capture in 1711 of Rio Janeiro, on

which he imposed a heavy contribution. In 1715 he was made *chef d'escadre*, and in 1728 *lieutenant général des armées navales*. He died in Paris on Sept. 27, 1736.

See his own *Mémoires* (1740), and J. Poullan, *Duguay-Trouin* (1882).

DU GUESCLIN, BERTRAND (c. 1320–1380), constable of France, one of the ablest captains of the Hundred Years War, was born of the lower Breton gentry at the castle of La Motte Broons (Dinan). The name is spelled in various ways in contemporary records, e.g., Claquen, Klesquen, Guesquen, Glayaquin, etc. He first gained fame at the tournament held at Rennes in 1338 to celebrate the marriage of Charles of Blois with Joan of Penthièvre. In the war which followed between Charles of Blois and John of Montfort for the possession of the duchy of Brittany, he put himself at the head of a band of adventurers and fought on the side of Charles and of France. He fought a brilliant action at the siege of Vannes in 1342, after which he disappeared from history for a number of years.

In 1354 he was sent to England with the lords of Brittany to negotiate for the ransom of Charles of Blois, who had been defeated and captured by the English in 1347. When Rennes and Dinan were attacked by the duke of Lancaster in 1356, Du Guesclin fought against the English, and at this time he engaged in a celebrated duel with Sir Thomas Canterbury. He finally forced his way with provisions and reinforcements into Rennes, which he defended till June 1357, when the siege was raised in pursuance of the truce of Bordeaux. Shortly afterward he passed into the service of the king of France.

In 1359, 1360, 1361 and 1362 he was continually in the field though he was twice a prisoner of the English. In May 1364 he defeated the Navarrese at Cochetel and took Jean de Grailly, the famous captain of Buch, prisoner. He had previously been made lord of Pontorson (1357), of La Roche Tesson (1361) and chamberlain (1364), he was now made count of Longueville and lieutenant of Normandy. Shortly afterward Du Guesclin was taken prisoner by Sir John Chandos at the battle of Auray, in which Charles of Blois was killed. Du Guesclin was ransomed for 100,000 crowns and was charged to lead the bands of discharged mercenaries, the famous *compagnies*, out of France. He marched with some of them into Spain, supported Henry of Trastámara against Peter the Cruel, helped to set the former upon the throne of Castile (1366) and was made constable of Castile and count of Trastámara.

He was defeated and captured by Peter's ally, the Black Prince, at Nájera in April 1367, but was soon released for a heavy ransom. Once more he fought for Henry, won the battle of Montiel (1369), reinstated him on the throne and was created duke of Molina.

In May 1370, at the command of Charles V, who appointed him constable of France, he returned to France. For nearly ten years he was engaged in fighting against the English in the south and the west of France, recovering from them the provinces of Poitou, Guenne and Auvergne.

In 1373, when the duke of Brittany sought English aid against a threatened invasion by Charles V, Du Guesclin seized the duchy, two years later he frustrated the attempt of the duke with an English army to recover it.

In 1380 he was sent into Languedoc to suppress disturbances and brigandage provoked by the harsh government of Louis I, duke of Anjou. His first act was to lay siege to the fortress of Châteauneuf-de-Randon, but on the eve of its surrender the constable died on July 13, 1380.

DUHAMEL, GEORGES (b. 1884—), French poet, novelist and playwright, born in Paris on June 30, 1884. His early life was one of struggle and hardship. He studied medicine, and in the Quartier Latin made the acquaintance of Romans, Valdrac and Arcos, with whom he founded the group of the *Abbaye* (q.v.) at Creteil. He obtained his medical degree in 1909, and until World War I he divided his activity between scientific research and

literary work. He made his name with a series of volumes of verse. *Selon ma Loi* (1910), and *Compagnons* (1912). Several plays of his were produced about the same time. *La Lumière* (1911), *Dans l'Ombre des Statues* (1912) and *Le Combat* (1913). It was, however, his two war books, *Vie des Marijors* (1916) and *Civilisation* (1918) which brought him before the public. After that he published a number of essays mainly directed to the creation of a new religious thought independent of any denomination, and to the promotion of understanding between the peoples of different nationalities. He also wrote a number of novels, five of which formed the Salavin cycle, *Vie et aventures de Salavin*, 5 vol. (1920–32), in which the Russian influence is combined with typically French restraint and interest in everyday things of life. Also well known is the *Chronique des Pasquiers*, 10 vol., 1933–43. Later writings included (Eng. trans.) *Why France Fights* (1940) and *Susanne and Joseph Pasquier* (1946).

DUHAMEL DU MONCEAU, HENRI LOUIS (1700–1782), French botanist and engineer, was born in Paris. His discovery of the fungus destroying the saffron plant in Gâtinais gained him admission to the Academy of Sciences in 1728. From then he devoted himself to vegetable physiology, and experimented on the growth and strength of wood, the growth of the mistletoe, on layer planting, on smut in corn, etc. He was probably the first, in 1736, to distinguish clearly between the alkalis, potash and soda. For many years he was inspector general of marine. He died in Paris on Aug. 13, 1782.

His principal works are *Tratado des arbores et arbustivos que se cultivent en France* (1755, 1768, 1835), *La Physique des arbores* (1758), *Des semis et plantations des arbores et de leur culture* (1760, 1835), *Éléments d'agriculture* (1762), *De l'exploitation des bois* (1764), *Tratado des arbores frutifers* (1768, 1835), *Éléments de l'architecture navale* (1783).

DÜHRING, EUGEN KARL (1833–1921), German philosopher and political economist, was born on Jan. 12, 1833, at Berlin, and died on Sept. 21, 1921. After a legal education he practised at Berlin as a lawyer till 1859. A weakness of the eyes, ending in total blindness, occasioned his taking up the studies with which his name is now connected. In 1864 he became *dozent* of the university of Berlin, but, in consequence of a quarrel with the professoriate, was deprived of his licence to teach in 1874. Among his works are *Kapital und Arbeit* (1865), *Der Wert des Lebens* (1865), *Natürliche Dialektik* (1865), *Kritische Geschichte der Philosophie* (1869), *Kritische Geschichte der allgemeinen Principien der Mechanik* (1872)—one of his most successful works, *Kursus der National- und Sozialökonomie* (1873), *Der Ersatz der Religion durch Volkswissenschaften* (1883). He published his autobiography in 1882 under the title *Sache, Leben und Feste*. Dühring's philosophy claims to be emphatically the philosophy of reality. He is passionate in his denunciation of everything which, like mysticism, tries to veil reality. He is almost Lucretian in his anger against religion which would withdraw the secret of the universe from our direct gaze. His "substitute for religion" is a doctrine in many points akin to Comte and Feuerbach, the former of whom he resembles in his sentimentalism. Dühring's opinions changed considerably after his first appearance as a writer. His earlier work, *Natürliche Dialektik*, in form and matter not the worst of his writings, is entirely in the spirit of the Critical Philosophy. Later, in his movement towards Positivism, he strongly repudiates Kant's separation of phenomena from noumenon, and affirms that our intellect is capable of grasping the whole reality. In political philosophy Dühring teaches an ethical communism and attacks the Darwinian principle of struggle for existence. In economics he is best known by his vindication of the American writer H. C. Carey, who attracts him both by his theory of value, which suggests an ultimate harmony of the interests of capitalist and labourer, and also by his doctrine of "national" political economy, which advocates protection on the ground that the morals and culture of a people are promoted by having its whole system of industry completed within its own borders. His patriotism is fervent, but narrow and exclusive. He idolized Frederick the Great and denounced Jews, Greeks, and the cosmopolitan Goethe.

See H. Druskowitz, *Eugen Duhring* (Heidelberg, 1888), E. Doll, *Eugen Duhring* (Leipzig, 1892), F. Engels, *Eugen D's Umwandlung der Wissenschaft* (Eng. trans. by E. Aveling, 1892, reprinted 1925), H. Vaihinger, *Hartmann, Duhring und Lange* (1876).

DUIKER or **DUIKERBOK**, small African antelopes (*Cephalophus* and allies). The popular name alludes to its habit of diving into and threading its way through thick bush. The genus *Cephalophus*, together with two other African genera, *Philotomus* and *Sylvicapra*, constitutes the tribe *Cephalophini*. Duikers are animals of small or medium size, frequenting thick forest. The horns, usually present in both sexes, are small and straight, situated far back on the forehead, and between them rises a crestlike tuft of hair. The common duiker (*S. gymnaea*) is found in bush country from the Cape to the Zambezi, Nyasaland and Angola. The banded duiker (*C. dorsalis*) from West Africa is golden brown with black transverse bands on back and loins. *C. sylvicultor*, of West Africa, is the largest species, and approaches a donkey in size. (See ANTELOPE, BOVIDAE.)

DUILIUS (or **DUELLIUS**), **GAUS**, Roman general during the first Carthaginian War, 266 B.C., when consul in command of the land forces in Sicily, he was appointed to supersede his colleague Cn. Cornelius Scipio Aemilianus as commander of the fleet. Recognizing that for the unskilled Romans the only chance of victory lay in fighting under conditions as similar as possible to those of a land engagement, he invented grappling irons (*corvus*) and boarding bridges, and gained a brilliant victory over the Carthaginian fleet off Mylae on the north coast of Sicily. A memorial column, adorned with the beaks of the captured ships, was set up in the Roman forum in honour of his victory.

DUISBURG, a town in the Prussian Government district (*Regierungsbezirk*) of Düsseldorf, Germany. It is situated at the junction of the Rhine and the Ruhr, 15 mi. N. (by rail) of Düsseldorf. Pop. (1885) 47,519, (1939) 431,256. Duisburg was known to the Romans as *Castrum Deutonis* and under the Frankish kings as *Disparigum*. In the 12th century it attained the rank of an imperial free town, but in the 17th century it was acquired by Brandenburg. Of the many churches in the town, the fine Gothic Salvatorkirche (15th century) is the most interesting. The town is well provided with educational facilities, of the technical schools, the school of machinery is important. In 1655, the elector Frederick William of Brandenburg founded a Protestant university, which flourished until 1802. The great development of industry on the Rhine made Duisburg into a large industrial town. Its chief industries are connected with metallurgical manufactures, in addition it has important chemical, textile, tobacco, sugar, soap, margarine and plate glass works, as an entrepot for the industries of the Ruhr area it exports large quantities of coal. The port—one of the largest inland ports of Europe—covers an area of 632 hectares. The Rhine-Herne canal connects Duisburg with Dortmund and by way of the Dortmund-Ems canal, with German North Sea ports. It is also an important railway centre. It was occupied by the Belgians from 1921 to 1925 as a sanction under the treaty of Versailles and was heavily bombed by the British in World War II.

DUJARDIN, FELIX (1801–1860), French biologist, was born at Tours on April 5, 1801, and died at Rennes on April 8, 1860. He forsook his early training in art and engineering for natural science, from 1843 concentrating on microscopic work in zoology. In 1840 he became dean of Rennes university, but two years later resigned to become a professor. In 1835 he distinguished protoplasm from other viscid substances, designating it "sarcode" and assigning to it all the qualities of life. He made detailed studies of rhizopods which he had discovered in 1834, and of oceanic foraminifera. Besides a manual of microscopic observation, he wrote *Natural History of Infusoria* (1841).

DUKAS, PAUL (1865–1935), French composer, born in Paris Oct. 1, 1865, studied under Matthias Dubois and Guraud. His cantata *Velleda* gained for him a second Grand Prix de Rome. The symphonic poem, *L'Apprenti Sorcier*, produced at the Société

Nationale de Musique in 1897, was an immediate success. His next important work was the music which he wrote for Maeterlinck's *Arsène et Barbe Bleue*, a lyrical story in 3 acts. This was played at the Opera Comique in 1907 and subsequently at many of the principal opera-houses in Europe. A "poème dansé," *The Peri*, in which the orchestration is extraordinarily rich, was produced in Paris in 1912 with the Russian dancer Mademoiselle Trouhanova. Dukas is a master of instrumentation, equally effective in bold colour effects and in the delicate passages which he touches in with so sure a hand. His works for piano include a sonata in E-flat minor and "Variations, Interlude and Final on a theme of Rameau," while his appreciation of the great harpsichord composers led him to edit a number of the works of Rameau, Couperin and Scarlatti. He was also a critic and a writer on music, held the position of inspector of music at the Beaux-Arts, was on the Conseil Supérieur of the Conservatoire and was an officer of the Légion d'Honneur.

See O. Seré, *Musiciens français d'aujourd'hui* (1911–12), G. Sama, *zeuhl, Un musicien français, Paul Dukas* (1913), V. d'Indy, *Emmanuel Chabrier et Paul Dukas* (1920), A. Coeuroy, *La musique française moderne* (1922).

DUK-DUK, a secret society of the New Britain Archipelago north east of New Guinea, in the South Pacific. The society has religious and political as well as social objects.

See "Duk-Duk and other Customs or Forms of Expression of the Melanesian's Intellectual Life," by Graf von Pfeil (*Journal of Anthrop. Instit.* vol. 27, p. 181), E. A. Weber, *The Duk Diks* (1929).

DUKE, the title of one of the higher orders of the European nobility, and of some minor sovereign princes. The word "duke," which is derived from the Lat. *dux*, a leader, or general, originally signified a leader, and more especially a military chief. In this general sense the word survived in English literature until the 16th century, but is now obsolete.

The origin of modern dukes is twofold. The *dux* first appears in the Roman empire under the emperor Hadrian, and by the time of the Gordians has already a place in the official hierarchy. He was the general appointed to command an expedition and his functions were purely military. In the 4th century, after the separation of the civil and military administrations, there was a duke in command of the troops in each of the frontier provinces of the empire, e.g., the *dux Britanniarum*. The number of dukes increased, and in the 6th and 7th centuries there were *duces* at Rome, Naples, Rimini, Venice and Perugia. They became charged with civil as well as military functions, and even exercised considerable authority in ecclesiastical administration. Under the Byzantine emperors they were the representatives in all causes of the central power. The Roman title of duke was less dignified than that of count (*comes*, companion) which implied an honourable personal relation to the emperor (see *COUNT*). Both titles were borrowed by the Merovingian kings for the administrative machinery of the Frank empire, and under them the functions of the duke remained substantially unaltered. He was a great civil and military official, charged to watch, in the interests of the crown, over groups of several *comitatus*, or countships, especially in the border provinces. The sphere of the dukes was never rigidly fixed, and their commission was sometimes permanent, sometimes temporary. Under the Carolingians the functions of the dukes remained substantially the same, but with the decay of the royal power in the 10th century both dukes and counts gained in local authority, the number of dukes became for the time fixed, and finally title and office were made hereditary, the relation to the crown being reduced to that of more or less shadowy vassalage. (See *FEUDALISM*.)

Side by side with these purely official dukedoms, however, there had continued to exist, or had sprung up, either independently or in more or less of subjection to the Frank rulers, national dukedoms, such as those of the Alemanni, the Aquitains, and later, of the Bavarians and Thuringians. These were developed from the early Teutonic custom by which the *herzog* (military chief) was elected by the nation as leader for a particular campaign, as in the case of the *heretogas* who had led the first Saxon invaders into Britain. Tacitus says of the ancient Germans *reges ex nobilitate*,

duces ex virtute sumunt, i.e., they elected their dukes for their warlike prowess only, and as purely military chiefs, whereas their kings were chosen from a royal family of divine descent. Sometimes the dukes so chosen succeeded in making their power permanent without taking the style of king. To this national category belong, besides the great German dukedoms, the dukes of Normandy, and the Lombard dukes of Spoleto and Benevento, who traced their origin, not to an administrative office, but to the leadership of Teutonic war bands. With the development of the feudal system the distinction between the official and the national dukedoms was more and more obliterated. By the 13th and 14th centuries the title had become purely territorial, and implied no necessary overlordship over counts and other nobles, who existed side by side with the dukes as tenants-in-chief of the crown. From this time the significance of the ducal title varies widely in different countries.

The abolition of the Holy Roman Empire in 1806 removed the shadow of vassalage from the German reigning dukes, who retained their sovereign status under the new empire. Only one, however, the grand duke of Luxembourg, remained both sovereign and independent. Besides those who were sovereign dukes in Germany there are certain "mediatized" ducal houses, e.g., that of Ratibor, which share with the dispossessed families of the Italian sovereign duchies certain royal privileges, notably that of equality of blood (*Ebenbürtigkeit*). In Italy, where titles of nobility give no precedence at court, that of duke (*duca*) has lost nearly all even of its social significance owing to lavish creations by the popes and minor sovereigns, and to the fact that the title often passes by purchase with a particular estate. Political significance it has none. Some great Italian nobles are dukes, notably the heads of the great Roman ducal families, but not all Italian dukes are great nobles.

In France the title duke at one time implied vast territorial power, as with the dukes of Burgundy, Normandy, Aquitaine and Brittany, who asserted a practical independence against the crown, though it was not till the 12th century that the title duke was definitely regarded as superior to others. At first (in the 10th and 11th centuries) it had no defined significance, and even a baron of the higher nobility called himself in charters duke, count or even marquis, indifferently. In any case the strengthening of the royal power sapped the significance of the title, until on the eve of the Revolution it implied no more than high rank and probably territorial wealth.

There were, under the *ancien régime*, three classes of dukes in France: (1) dukes who were peers (*see* PEERAGE) and had a seat in the parliament of Paris, (2) hereditary dukes who were not peers, (3) "brevet" dukes, created for life only. The French duke ranks in Spain with the "grandee" (*q.v.*), and vice versa. In republican France the already existing titles are officially recognized, but they are now no more than the badges of distinguished ancestry. Besides the descendants of the feudal aristocracy there are in France certain ducal families dating from Napoleon I's creation of 1806 (e.g., ducs d'Albafra, de Montebello, de Feltre), from Louis Philippe (duc d'Isly, and duc d'Audiffret-Pasquier), and from Napoleon III (Malakoff, Magenta, Morny).

In England the title of duke was unknown till the 14th century, though in Saxon times the title ealdorman, afterwards exchanged for "earl," was sometimes rendered in Latin as *dux*, and the English kings till John's time styled themselves dukes of Normandy, and dukes of Aquitaine even later. In 1337 King Edward III. erected the county of Cornwall into a duchy for his son Edward the Black Prince, the first English duke. The second was Henry, earl of Lancaster, Derby, Lincoln and Leicester, created duke of Lancaster in 1357. In Scotland the title of duke was first bestowed in 1308 by Robert III. on his eldest son David, who was made duke of Rothesay, and on his brother, who became duke of Albany.

British dukes rank next to princes and princesses of the blood royal, the two archbishops of Canterbury and York, the lord chancellor, etc., but beyond this precedence they have no privileges which are not shared by peers of lower rank (*see* PEERAGE). Though their full style as proclaimed by the herald is "most

high, potent and noble prince," and they were included in the *Almanach de Gotha*, they were not recognized as the equals in blood of the crowned or mediatized dukes of the Continent, and the daughter of a British duke marrying a foreign royal prince could only take his title by courtesy, or where, under the "house laws" of certain families, a family council sanctioned the match. The eldest son of a British duke takes as a rule by courtesy the second title of his father, and ranks, with or without the title, as a marquis. The other sons and daughters bear the titles "Lord" and "Lady" before their Christian names, also by courtesy. A duke in the British peerage, if not royal, is addressed as "Your Grace" and is styled "the Most Noble." (*See* ARCHDUKE, GRAND DUKE, and, for the ducal coronet, CROWN AND CORONET.) (W. A. P.)

DUKE ENDOWMENT, THE, an American charity fund established by James B. Duke by indenture dated Dec. 11, 1924. The administration of the fund is vested in a self-perpetuating board of 15 trustees. The initial gift by Duke somewhat exceeded \$40,000,000 in value. Of this amount up to \$6,000,000 was to be used in connection with building and equipping Duke university. Twenty per cent of the net income is to be reinvested until such reinvestments aggregate \$40,000,000. The remaining income is distributable as follows: Duke university, 32%, hospitals not operated for private gain in North and South Carolina, 31%, Davidson college, 5%, Furman university, 5%, Johnson C. Smith university, 4%, orphanages in North and South Carolina, 10%, superannuated preachers having served in a North Carolina conference of the Methodist Episcopal Church, South, 2%, building and operating rural churches of the Methodist Episcopal Church, South, in North Carolina, 6% and 4% respectively. By his will Duke added to the fund \$10,000,000 together with two-thirds of his residuary estate. Of the \$10,000,000, \$4,000,000 may be used for providing hospital, medical school and nurses' home facilities at Duke university, the income from the balance of \$10,000,000 going to Duke university. He further provided that \$7,000,000 out of two thirds of the residuary estate are to be used for purposes of building and equipping Duke university, 10% of the income going to Duke university and 90% for the benefit of hospitals not operated for private gain in North and South Carolina.

DUKE OF EXETER'S DAUGHTER, a 15th century instrument of torture resembling the rack. (*See* TORTURE.)

DUKERIES, THE, a district in the north west of Nottinghamshire, England, forming part of Sherwood forest (*q.v.*). The name was taken from the existence of several adjacent demesnes of noblemen, and the character of the forest is to some extent preserved here. On the north is the Lincoln, Retford, Worksop, Sheffield branch and on the south, the Lincoln, Ollerton, Chesterfield branch of the L.N.E. railway. The following demesnes are in the district: Worksop Manor formerly belonged to the dukes of Norfolk; Welbeck Abbey, the seat of the dukes of Portland, to whom it came from the Cavendish family (dukes of Newcastle), is mainly classic in style, dating from the early 17th century, but with many subsequent additions, the fifth duke of Portland (d. 1879) built the curious series of subterranean corridors and chambers beneath the grounds. Clumber House, the seat of the dukes of Newcastle, was demolished in 1938. Thoresby Park is the seat of the Pierrepont family (earls Manservants). Part of this demesne is a splendid tract of wild woodland.

DUKES, LEOPOLD (1810-1891), Hungarian critic of Jewish literature. He spent about twenty years in England, and from his researches in the Bodleian library and the British Museum (which contain two of the most valuable Hebrew libraries in the world) Dukes was able to complete the work of Zunz (*q.v.*). The most popular work of Dukes was his *Rabbinische Blumenlese* (1844), in which he collected the rabbinic proverbs and illustrated them from the gnostic literatures of other peoples. Dukes made many contributions to philology, but his best work was connected with mediæval Hebrew poetry, especially Ibn Gabirol.

DUKE UNIVERSITY at Durham, North Carolina, U.S.A., owes its existence to a trust established by James B. Duke Dec. 11, 1924 (*see* DUKE ENDOWMENT). The university is

A. P. C. Y. R. O. C. P. H. I. C. C. E.
THE MAIN UNIT OF DUKE UNIVERSITY WHICH CONSISTS OF SOME 40 BUILDINGS ON A 1,500 ACRE WOODLAND CAMPUS. THE UNIVERSITY CHAPEL LEFT HAS A TOWER RISING 210 FEET ABOVE GROUND LEVEL. THE GENERAL ARCHITECTURAL SCHEME IS GOTHIC AND THE BUILDINGS ARE OF NATIVE NORTH CAROLINA STONE.

built around Trinity college, founded 1838

After spending two years in college, including summer reading, the ablest students may enter the professional schools or continue in the advanced college or university courses

The woman's college provides for women educational opportunities equal to those provided for men in Trinity college. The graduate school of arts and sciences with the purpose of differentiating more sharply between the college and the graduate school, gives to the work of the latter a more distinctively university character than has heretofore been the rule in the United States. This school aims at developing those especially fitted for teaching, but special emphasis is laid on research, mathematics, chemistry, physics, biology (in close co-operation with the medical school) and on the social sciences including law. The school of medicine runs through four quarters, so that a four-year medical course may be completed in three calendar years. The school of law provides liberal training in law as one of the social sciences closely allied with government, economics and business administration. A university press is maintained, and in 1943 issued the *South Atlantic Quarterly*, the *Hispanic American Historical Review*, *American Literature*, *Ecological Monographs*, *Character and Personality*, *Duke Mathematical Journal*, the *Southern Association Quarterly* and *Law and Contemporary Problems*. In the academic year 1942-43 there were 5,121 students, exclusive of the summer school, and a teaching staff of 511. The endowment was \$38,963,698.

Fox, *Twenty-five Years of Trinity College* (Trinity College President's Reports 1917, and *Trinity Alumni Register*, vol. iii, p. 140-167); E. C. Brooks, *Trinity Alumni Register*, vol. i, p. 4-18, 89-101; 247-257, vol. ii, p. 248-258, 309-321, vol. iii, p. 1-12, 169-185; vol. iv, p. 1-10, W. T. Laprade, *Trinity Alumni Register*, vol. viii, p. 4-8.

(W. P. F. X.)

DUKINFIELD, a municipal borough in the Stalybridge and Hyde parliamentary division of Cheshire, Eng., 6 mi. E. of Manchester. Pop. (1951) 18,445. Area 2.7 sq. mi. It lies opposite Ashton-under-Lyne on the south bank of the Tame river which there forms the boundary between Cheshire and Lancashire.

The chief industries are cotton manufactures and engineering. In the chapel of Dukinfield hall (the hall is now demolished but the chapel is still used) Samuel Eaton (d. 1665) taught the first

Congregational church in the north of England. The borough was incorporated in 1899.

DULAC, EDMUND (1882-1953), British illustrator, was born at Toulouse, Fr., on Oct. 22, 1882, and became a British subject in 1912. His best known illustrations were for traditional fairy tales, but his work also included pictures for *The Tempest* (1908), *The Ru baryat of Omar Khayyam* (1909), *Treasure Island* (1927) and *The Marriage of Cupid and Psyche* (1951). He designed stamps for the coronation of King George VI and bank notes and stamps for the Free French, and was a successful portraitist.

Dulac died in London on May 25, 1953.

DULCIGNO, a seaport of Montenegro, Yugoslavia, on the Adriatic sea. Population 3,748, chiefly Albanians and Turks. Shut in by hills and forests, Dulcigno is the prettiest of Montenegrin towns. The old quarter, built on a promontory, is walled and has a mediaeval castle. There is a Roman Catholic cathedral and an ancient Latin church. Steamers call, and some shipbuilding and fishing are carried on, but the harbour lacks shelter, and is liable to silting. Like the rest of Montenegro, the port in 1941 came under Italian control.

To the Romans, who captured the town in 167 B.C. Dulcigno was known as Ulcinium or Olcumum, in the middle ages it was a noted haunt of pirates, in 1571 it was captured by the Turks from the Venetians. In 1718 it was the scene of a great Venetian defeat, in 1877 the Montenegrins took it from the Turks and in 1878 it was ceded to them by the treaty of Berlin. The Turks however held it till 1880 when the "Dulcigno demonstration" by the fleets of the great powers forced them to relinquish it.

DULCIMER, the prototype of the pianoforte (*q.v.*), an instrument of great antiquity derived originally from the east, consisting of a horizontal sound chest over which are stretched a varying number of wire strings set in vibration by strokes of little sticks or hammers. The dulcimer differed from the psalterium or psaltery chiefly in the manner of playing, the latter having the strings plucked by means of fingers or plectrum, a distinction the importance of which was fully recognized when the invention of the pianoforte had become a matter of history. It was then perceived that the psalterium in which the strings

16TH CENTURY FRENCH DULCIMER AND HAMMERS WITH WHICH IT IS PLAYED

The direct ancestor of the piano, the dulcimer came originally from the east, being introduced to Europe probably during the Crusades. It was popular throughout the middle ages. In the days of Louis XIV of France elaborate models were constructed.

were plucked, and the dulcimer in which they were stuck when provided with keyboards, gave rise to two distinct families of instruments, differing essentially in tone quality, in technique and in capabilities. The evolution of the psalterium stopped at the harpsichord, that of the dulcimer gave us the pianoforte. The dulcimer was very popular all over Europe throughout the middle ages.

The pantaleon, a double dulcimer, named after the inventor, Pantaleon Hebenstreit of Eisleben, a violinist, had two sound boards, 185 strings, one scale of overspun catgut and one of wire. Hebenstreit travelled to Paris with his monster dulcimer in 1705 and played before Louis XIV, who baptized it *Pantaleon*. Quantz and Quirin of Blankenburg both gave descriptions of the instrument.

DULKEN, town, Prussian Rhine province, Germany, 11 mi by rail SW from Crefeld Pop. (1939) 15,952. It has a Gothic parish church. There are manufactures of linen, cotton, silk and velvet, etc., ironworks and foundries.

DULONG, PIERRE LOUIS (1785-1838), French chemist and physicist, was born at Rouen on Feb. 12 (or 13), 1785. After acting as assistant to Berthollet, he became successively professor of chemistry at the faculty of sciences and the normal and veterinary schools at Alfort, and then (1820) professor of physics at the École Polytechnique, of which he was appointed director in 1830. He died in Paris on July 18 (or 19), 1838.

His earliest work was chemical in character. In 1811 he discovered nitrogen trichloride, during his experiments serious explosions occurred twice, and he lost an eye, besides sustaining severe injuries to his hand. He also investigated the oxygen compounds of phosphorus and nitrogen, and was one of the first to hold the hydrogen theory of acids.

Dulong's important research work in physics was on heat and was carried out in conjunction with Alexis Thérèse Petit (1791-1820), the professor of physics at the École Polytechnique. In 1815 they made the first accurate comparisons between the mercury and the air thermometer. The first published research (1816) dealt with the dilatation of solids, liquids and gases and with the exact measurement of temperature, and it was followed by one in 1817 in which they showed that Newton's law of cooling was only true for small differences in temperature, and one in 1818 on the measurement of temperature and the transference of heat, which was crowned by the French academy. In another, "On some important points in the theory of heat" (1819), they stated the "law of Dulong and Petit" dealing with atomic heats. Subsequent papers by Dulong were concerned with "New determinations of the proportions of water and the density of certain elastic fluids" (1820, with Berzelius), the property possessed by certain metals of facilitating the combination of gases (1823 with Thénard), the refracting powers of gases (1826), and the specific heats of gases (1829). In 1830 he published a research, undertaken with Arago for the Academy of Sciences, on the elasticity of steam at high temperatures. In his last paper, published posthumously in 1838, Dulong gave an account of experiments made to determine the heat developed in a chemical reaction, together with a description of the calorimeter he employed. He was so badly supplied with apparatus that he spent practically all his wealth in providing what was necessary for his researches.

DULSE, in botany, *Rhodymenia palmata*, one of the red seaweeds, consisting of flat solitary or tufted purplish-red fronds, fan-shaped in general outline and divided into numerous segments, which are often again and again divided in a forked manner. It varies much in size and degree of branching, ranging from 5 to 12 or more inches long. It grows on rocks, shellfish or larger seaweeds, and is used by the poor in Scotland and Ireland as a relish with their food. It is commonly dried and eaten raw, the flavour being brought out by long churning. In the Mediterranean it is used cooked in ragouts and made dishes.

DULUTH, a city of Minnesota, U.S.A., on the western tip of Lake Superior, at the mouth of the St. Louis river, opposite Superior, Wis., the county seat of St. Louis county. It is on federal highways 2, 53 and 61, and is served by the Chicago, St. Paul, Minneapolis and Omaha, the Duluth, Missabe and Iron

Range, the Duluth, South Shore and Atlantic, the Great Northern, the Northern Pacific, the Soo Line, the Chicago, Milwaukee, St. Paul and Pacific and the Duluth, Winnipeg & Pacific railways, by Northwest Airlines and Wisconsin Central Airlines and by many Great Lakes freight lines. The population was 104,066 in 1950 and was 101,065 in 1940 by the federal census. It is one of the coolest of U.S. cities during summer, the average spring and summer

BY COURTESY OF THE OFFICE OF THE CHIEF OF ENGINEERS, DULUTH
A VIEW OF DULUTH HARBOUR BASIN SHOWING COAL DOCKS AND ELEVATORS

temperature is 62.5°. The city has a beautiful site (62.3 sq mi land area) on slopes rising to 600 ft above the level of the lake, commanding fine views of harbour, lake, river and surrounding country. A 25 mi boulevard runs along the top of the bluff back of the city, and there are 3,216 ac in public parks. The Duluth Superior harbour, with 49 mi of water frontage, formed by thin narrow strips of land projecting from either shore (Minnesota point and Wisconsin point) is one of the finest in the world, and it ranks second only to New York city, among U.S. ports, in the commercial tonnage handled. It is well equipped with modern machinery for transferring cargoes, and had (1950) 21 coal docks, 7 iron ore docks, 46 wharves for general freight, 25 grain elevators and a cement storage elevator with a capacity of 114,000 bbl. Its commerce in 1949 was 56,673,901 tons, consisting largely of iron ore from the Vermilion, Cuyuna and Mesabi ranges, wheat and other grains from the Red river valley and the plains of Canada, butter and eggs from adjacent territory, automobiles and coal from Lake Erie ports. Among the manufacturing industries, the largest are the great mills of the American Steel and Wire company, established there in 1909. In 1912 a commission form of government was adopted. A zoning ordinance was adopted in 1925, and the city's development came under the supervision of a planning commission. The recreation system includes provision for flying, skiing, curling and iceboating, as well as for the more usual sports. The charitable agencies are financed through a joint community chest. There are two daily papers. In 1951 there were 37 public and 21 parochial schools, the College of St. Scholastica, the Duluth Branch of the University of Minnesota and an extension department of the University of Minnesota. The federal government maintains a coast guard station, a naval reserve training station, a national guard air base and a weather bureau there.

Duluth's Civic Symphony orchestra and its amateur Little theatre rank among the finest in the country. Its Fall festival is a colourful annual event. Points of interest include the Chisholm Memorial museum, the St. Louis County Historical Society museum, the Northern Bible Society museum, the scenic Skyline Parkway boulevard and Lake Superior North Shore drive, the municipal Zoological Gardens, Enger Memorial Observation tower and the Tweed Art galleries of the University of Minnesota, Duluth Branch.

The first visitor on record to the site of Duluth was Daniel Greysolon, Sieur Dulhut (d. 1709), a French trader and explorer, who about 1679 built a stockaded trading post at the mouth of Pigeon river on the north shore of the lake. About 1752 a second trading post, which later became a depot of Astor's American Fur company, was established in the vicinity. Permanent settlement on the site of the city began in 1853. In 1870, when the city was incorporated and the first railway reached it, the population was 3,131, and in 1880 it was only 3,483. Between 1880 and 1890, with

the development of railways, of commerce on Lake Superior and of the iron mines of northern Minnesota, the population increased nearly tenfold, to 31,115. The traffic of the port increased from 2,848,672 tons in 1890 to 46,875,416 tons in 1913, fluctuated considerably during World Wars I and II, and reached its maximum (to mid 20th century) in 1942, when the commerce was 74,314,646 tons.

DULWICH, a county and parliamentary division in the metropolitan borough of Camberwell, London, England, with stations at East, North and West Dulwich on the Southern railway. Pop (1931) 60,643. It comprises the southern end of the borough from Denmark Hill and Peckham to upper Sydenham and the Crystal Palace. West Dulwich, in which the College is situated, with its wooded lanes descending from the Sydenham hill, still retains much of its rural character. The manor, which had belonged to the Cistercian monks of Bermondsey, passed through various hands to Edward Alleyn (q.v.) in 1606. His foundation of the College of God's Gift, commonly called Dulwich College, was opened with great state on Sept. 13, 1619, in the presence of Lord Chancellor Bacon, Inigo Jones and other distinguished men. According to the letters patent the almspeople and scholars were to be chosen from the parishes of St. Giles, St. Botolph without Bishopsgate, and St. Saviour's (Southwark). By a series of statutes signed in 1626, Alleyn ordained that his school should consist of three distinct classes — (1) twelve poor scholars, (2) children of inhabitants of Dulwich, who were to be taught freely, and (3) "towne or foreign scholars." The almspeople consisted of six "poor brethren" and six "poor sisters," and the head of the teaching and governing staff was to consist of a master and a warden, who were always to be of the founder's surname.

The founder's intention to establish a great public school, with provision for university training, is shown by the statutes, but for more than two centuries the educational benefits were restricted to the twelve poor scholars. In 1857 and 1882, however, the foundation was entirely reconstituted. It now comprises two schools, called respectively Dulwich College and Alleyn's school. The former is one of the important English public schools, the buildings (1866-70) by Charles Barry contain a fine hall. The college possesses one of the leading private picture galleries in the country, the bequest mainly of Sir P. F. Bourgeois, R.A., in 1811, with later additions and a separate endowment. The Dutch and Flemish schools in particular are well represented, together with some fine examples of the Spanish, French and British. Dulwich park (72 ac.) was presented to the public in 1890.

DUMA, an old Russian word meaning thought, in connection with the adjective *Gosudarstvennaya* (of Empire) was the name of the first Russian House of Representatives, granted by Nicholas II (Oct. 30, 1905), and after the amendment of the electoral law (Dec. 24, 1905), formally sanctioned on March 5, 1906. Electors were distributed in six "curias" — large landed proprietors, small landed proprietors, peasants, capitalists, middle class, working men. Direct voting was admitted only in six large cities. The remaining population elected electors, who in their turn elected the electors to upper local units, from which the electors were finally sent to provincial assemblies to elect members of the Duma. Thus peasants elected in four cities (Vladivostok, Ussuriysk, province), small landowners in their proprietors, district, province, as well as working men (factory, district, province), big landowners, rich citizens and middle class citizens in two (district, province). The number of electors given to various constituencies varied in opposite proportion to the number of population, thus giving enormous preponderance to the upper classes. In 1907, about 200,000 had the right to choose 2,204 electors, wealthy citizens (500,000) 788, middle class (8,000,000) 590, working men (12,000,000) 112, peasants (70,000,000) 1,168. The Duma had the power to legislate, to vote the Budget and to control the administration. But its rights were extremely curtailed by the tsar's prerogative, through indiscriminate use of Orders in Council, to thwart regular legislation, by withdrawing from its competence a great part of Budget expenses, by the lack of responsibility of ministers and, last, not least, by an extremely con-

servative Upper House (the Council of Empire) composed half of old dignitaries nominated by the tsar and half of elected members from gentry, church, commerce, and learned bodies.

The first two Dumas were dissolved after 73 and 103 days of existence. The third Duma, elected after a change of electoral law, lasted for the full five years of its mandate (1907-12), and the fourth (1912-17) was nearing its end when the March revolution began.

See also RUSSIA, *History* and P. N. Milyukov's article on "The Representative System in Russia" in "*Russian Realities and Problems*," ed. J. D. Duff (1917).

DUMAGUETE, a municipality (with administrative centre and 23 *barrios* or districts) and capital of the province of Negros Oriental, of the island of Negros, Philippine islands, on Tuguegarai strait, 4.4 mi from Manila. Pop (1939), 22,236, of whom 67 were whites. It is the centre of a fertile agricultural region which supports a flourishing trade. Siliman Institute, a Presbyterian school, founded early in the century, has done excellent work in educating the natives. Of those aged 6 to 19, inclusive 42.2% were reported in 1939 as attending school and of those ten years old and over 53.7% were reported as literate. The vernacular is a dialect of Bisayan. There is also a meteorological station. The number of parcels of land declared for taxation in 1938 was 8,172 and the number of owners 6,117.

DUMANJUG, a municipality (with administrative centre and 23 *barrios* or districts), of the province and island of Cebu, Philippine islands, on the west coast at the mouth of the Dumanjug river, about 40 mi SW of Cebu, the provincial capital. Pop (1939), 20,973, of whom two were white. Communication with Sibonga, a municipality situated on the opposite shore of the island is accomplished through one of the few passes of the mountains in the interior. Corn and sugar are grown in the neighbouring region and there is an important coastwise trade. There is little industry, aside from agriculture. Cebuano is the vernacular.

DUMAS, ALEXANDRE (ALEXANDRE DAVY DE LA PAILLETERIE) (1802-1870), French novelist and dramatist, was born at Villers Cotterets (Aisne) on July 24, 1802. His father, General Dumas (Alexandre Davy de la Paillette) was born in San Domingo, the natural son of Antoine Alexandre Davy, marquis de la Paillette, by a negress, Marie Cessette Dumas, who died in 1772. In 1780 he accompanied the marquis to France, and there the father made a mésalliance which drove the son into enlisting in a dragoon regiment. The young Alexandre Dumas was still a private at the outbreak of the revolution, but he rose rapidly and became general of division in 1793. He was general in chief of the army of the western Pyrenees, and was transferred later to commands in the Alps and in La Vendée. Among his many exploits was the defeat of the Austrians at the bridge of Clausen on April 22, 1797, where he commanded Joubert's cavalry. He lost Napoleon's favour by plain speaking in the Egyptian campaign, and later returned to France to spend the rest of his days in retirement at Villers Cotterets, where he had married in 1792 Marie Elisabeth Labouret.

The novelist, who was the offspring of this union, was not four years old when General Dumas died (1806), leaving his family with no further resource than 30 acres of land. Mme Dumas tried to obtain help from Napoleon, but in vain, and lived with her parents in narrow circumstances. Alexandre received the rudiments of education from a priest, and entered the office of a local solicitor. His chief friend was Adolphe de Leuven, the son of an exiled Swedish nobleman implicated in the assassination of Gustavus III of Sweden, and the two collaborated in various vaudevilles and other pieces which never saw the footlights. Leuven returned to Paris, and Dumas was sent to the office of a solicitor at Crepy. In 1823 Dumas visited his friend in Paris, and was received by Talma. He then determined to seek his fortune in Paris. An introduction to General Foy procured for him a place as clerk in the service of the duke of Orleans, and he began to collaborate with Leuven in the production of vaudevilles and melodramas. Madame Dumas presently joined her son in Paris, where she died in 1838. Soon after his arrival in Paris Dumas

had entered on a liaison with a dressmaker, Marie Catherine Labay, and their son, the famous Alexandre Dumas fils (see below) was born in 1824. Dumas acknowledged his son in 1831, and obtained the custody of him after a lawsuit with the mother.

AS DRAMATIST AND NOVELIST

His Plays—The first piece by Dumas and Leuven to see the footlights was *La Chaise et l'amour* (Ambigu Comique, Sept. 22, 1825), and in this they had help from other writers. Dumas had a share in another vaudeville, *La Noce et l'enterrement* (Porte Saint Martin, Nov. 21, 1826). It was under the influence of the Shakespeare plays produced in Paris by Charles Kemble, Harriet Smithson (afterwards Mme Berlioz) and an English company that the romantic drama of *Christine* was written. The subject was suggested by a bas relief of the murder of Monaldeschi exhibited at the Salon of 1827. The piece was accepted by the Comédie Française, but its production was deferred. Meanwhile Dumas had written, in prose, *Henri III et sa cour*, which was immediately accepted by the Comédie Française and produced on Feb. 11, 1829. It was the first great triumph of the romantic drama. The brilliant stagecraft of the piece and its admirable historical setting delighted an audience accustomed to the decadent classical tragedy, and brought him the friendship of Hugo and Vigny. His patron, the duke of Orleans now gave him the librarianship of the Palais Royal. *Christine* was recast as a romantic trilogy in verse in five acts with a prologue and epilogue, with the sub title of *Stockholm, Fontainebleau, Rome*, and was produced by Harel at the Odéon in March 1830.

The revolution of 1830 temporarily diverted Dumas from letters. The account of his exploits should be read in his *Mémoires*, where the incidents lose nothing in the telling. He finally alienated himself from the Orleans Government by being implicated in the disturbances which attended the funeral of General Lamarque in June 1832, and he received a hint that his absence from France was desirable. A tour in Switzerland undertaken on this account furnished material for the first of a long series of amusing books of travel. Dumas remained, however, on friendly and even affectionate terms with the young duke of Orleans until his death in 1842. Meanwhile he had produced *Napoléon Bonaparte* (Odéon, Jan. 10, 1831), his unwillingness to make a hero of the man who had slighted his father having been overcome by Harel, who put him under lock and key until the piece was finished. His next play, *Antony*, had a real importance in the history of the romantic theatre. It was put in rehearsal by Mlle Mars, but so unsatisfactorily that Dumas transferred it to Bocage and Mme Dorval, who played it magnificently at the Porte Saint Martin theatre on May 3, 1831. The Byronic hero Antony was a portrait of himself in his relations with Melanie Waldor, except of course in the extravagantly melodramatic denouement, when Antony, to save his mistress's honour, kills her and exclaims, "Elle me résistait, je l'ai assassinée." He produced more than 20 more plays alone or in collaboration before 1845, exclusive of dramatizations from his novels. *Richard Darlington* (Porte Saint Martin, Dec. 10, 1831), the first idea of which was drawn from Sir Walter Scott's *Chronicles of the Canongate*, owed part of its great success to the admirable acting of Frederick Lemaître. *La Tour de Nesle* (Porte Saint Martin, May 29, 1832), announced as by MM. X. X. and Gaillardet, was the occasion of a duel and a lawsuit with the original author, Frédéric Gaillardet, whose manuscript had been revised, first by Jules Janin and then by Dumas. In rapidity of movement, and in the terror it inspired, the piece surpassed *Henri III* and *Antony*. A lighter drama, *Mademoiselle de Belle-Isle* (Théâtre Français, April 2, 1839), long held the stage.

In 1840 Dumas married Ida Fernier, an actress whom he had imposed on the theatres that took his pieces. The amiable relations which had subsisted between them for eight years were disturbed by the marriage, which is said to have been undertaken in consequence of a strong hint from the duke of Orleans, and Mme Dumas lived in Italy separated from her husband.

His Novels—As a novelist Dumas began by writing short stories, but his happy collaboration with Auguste Maquet, which

began in 1839, led to the admirable series of historical novels in which he proposed to reconstruct the whole course of French history. In 1844 he produced, with Miquet's help, that most famous of "cloak and sword" romances, *Les Trois Mousquetaires* (8 vols.), the material for which was discovered in the *Mémoires de M. d'Artagnan* (Cologne, 1701-02) of Courtlès de Sandras. The adventures of d'Artagnan and the three musketeers, the gigantic Porthos, the clever Aramis, and the melancholy Athos, who unite to defend the honour of Anne of Austria against Richelieu and the machinations of "Milady," are brought down to the murder of Buckingham in 1628. Their admirers were gratified by two sequels, *Vingt ans après* (10 vols., 1845) and *Dix ans plus tard, ou le vicomte de Bragelonne* (16 pts., 1848-50), which opens in 1660, showing us a mature d'Artagnan, a respectable captain of musketeers, and contains the magnificent account of the heroic death of Porthos. The three musketeers are as famous in England as in France. Thackeray could read about Athos from sunrise to sunset with the utmost contentment of mind, and R. L. Stevenson and Andrew Lang have paid tribute to the band in *Memoirs and Portraits and Letters to Dead Authors*. Before 1844 was out Dumas had completed a second great romance in 12 volumes, *Le Comte de Monte-Cristo*, in which he had help from Fiorentino as well as from Maquet. The idea of the intrigue was suggested by Peuchet's *Police d'Espagne*, and the stress laid on the earlier incidents, Dantes, Duglars and the Chateau d'If, is said to have been an afterthought. Almost as famous as these two romances is the set of Valois novels of which Henri IV is the central figure, beginning with *La Reine Margot* (6 vols., 1845), which contains the history of the struggle between Catherine of Medicis and Henry of Navarre, the history of the reign of Henry III is told in *La Dame de Monsoreau* (8 vols., 1846), generally known in English as *Clotilde the Jester*, from its principal character, and in *Les Quarante cinq* (10 vols., 1847-48), in which Diane de Monsoreau avenges herself on the duke of Anjou for the death of her former lover, Bussy d'Amboise.

Much has been written about the exact share which Dumas had in the novels which bear his name. The Dumas Maquet series is undoubtedly the best, but Maquet alone never accomplished anything to approach them in value. The mass of the novels still exist in Dumas's handwriting, and the best of them bear the unmistakable stamp of his unrivelled skill as a narrator. The chief key to his enormous output is to be found in his untiring industry and amazing fertility of invention, not in the system of wholesale collaboration which was exposed with much exaggeration by Querard in his *Supercheries littéraires* and by "Eugène de Mirecourt" (C. B. J. Jacquot) in his misleading *Fabrique de romans, maison Alexandre Dumas et cie* (1845). His assistants, in fact, supplied him with outlines of romances on plans drawn up by himself, and he then rewrote the whole thing. That this method was never abused it would be impossible to say, *Les Deux Diane*, for instance, a prelude to the Valois novels, is said to have been written entirely by Paul Meurice, although Dumas's name appears on the title-page.

LATER YEARS

The latter part of Dumas's life is a record of excessive toil to meet prodigal expenditure and accumulated debts. His disasters began with the building of a house in the Renaissance style, with a Gothic pavilion and an "English" park, at Saint Germain-en-Laye. This place, called Monte-Cristo, was governed by a crowd of hangers on of both sexes, who absorbed Dumas's large earnings and left him penniless. Dumas also founded the Theatre Historique chiefly for the performance of his own works. The enterprise was under the patronage of the duc de Montpensier, and was under the management of Hippolyte Hostein, who had been the secretary of the Comédie Française. The theatre was opened in Feb. 1847 with a dramatic version of *La Reine Margot*. Meanwhile Dumas had been the guest of the duc de Montpensier at Madrid, and made a quasi official tour to Algeria and Tunis in a Government vessel, which caused much comment in the press. Dumas had never changed his republican opinions. He greeted the revolution of 1848 with delight, and was even a sandi-

date for electoral honours in the department of the Yonne. But the change was fatal to his theatrical enterprise, for the failure of which in 1850 he was made financially responsible. His son, Alexandre Dumas, was at that time living with his mother Mlle Labay, who was eventually reconciled with the elder Dumas. Father and son, though always on affectionate terms when they met, were too different in their ideas to see much of one another. After the *coup d'état* of 1851 Dumas crossed the frontier to Brussels, and two years of rapid production, and the economy of his secretary, Noël Parfait, restored something like order to his affairs. On his return to Paris in the end of 1853 he established a daily paper, *Le Mousquetaire*, for the criticism of art and letters. It was chiefly written by Dumas, whose *Mémoires* first appeared in it, and survived until 1857, when it was succeeded by a weekly paper, *Le Monte Cristo* (1857-60). In 1858 Dumas travelled through Russia to the Caucasus, and in 1860 he joined Garibaldi in Sicily. After an expedition to Marselles in search of arms for the insurgents, he returned to Naples, where Garibaldi nominated him keeper of the museums. After four years' residence in Naples he returned to Paris, and after the war of '66 he visited the battlefields and produced his story of *La Furieuse prussienne*. But his powers were beginning to fail and in spite of the 1,200 volumes which he told Napoleon he had written, he was at the mercy of his creditors, and of the succession of theatrical ladies who tyrannized over him and feared nothing except the occasional visits of Dumas fils. He was finally rescued from these by his daughter, Mme Pétel, who came to live with him in 1868, and two years later, on Dec. 5, 1870, he died in his son's house at Puy, near Dieppe.

Auguste Maquet was Dumas's chief collaborator. Others were Paul Lacroix (the bibliophile "P. L. Jacob"), Paul Bocage, J. P. Mallefille and P. A. Fiorentino. The novels of Dumas may be conveniently arranged in a historical sequence. The Valois novels and the musketeers series brought French history down to 1672. Contributions to later history are—*La Dame de volupé* (2 vols., 1864), being the memoirs of Mme de Luynes, and its sequel *Les Deux Renes* (2 vols., 1864), *La Tulipe noire* (3 vols., 1850), giving the history of the brothers de Witt, *Le Chevalier d'Hermental* (4 vols., 1853), and *Une Fille du régent* (4 vols., 1845), the story of two plots against the regent, the duke of Orleans, two books on Mme du Defand, *Mémoires d'une aveugle* (8 vols., 1856-57) and *Les Confessions de la marquise* (8 vols., 1857) both of doubtful authorship, *Olympe de Clèves* (9 vols., 1852), the story of an actress and a young Jesuit novice in the reign of Louis XV, one of his most popular novels, five books on the beginning of the Revolution down to the execution of Marie Antoinette the *Mémoires d'un médecin*, including *Joseph Balsano* (19 pts., 1846-48), in which J. J. Rousseau, Mme du Barry and the dauphiness Marie Antoinette figure, with its sequels, *Le Collier de la reine* (9 vols., 1849-50), in which Balsano appears under the alias of Cagliostro, *Ange Pitou* (8 vols., 1852), known in English as "The Taking of the Bastille", *La Comtesse de Charny* (19 vols., 1853-55), describing the attempts to save the monarchy and the flight to Varennes, and *Le Chevalier de maison rouge* (6 vols., 1846), which opens in 1793 with the hero's attempt to save the queen. Among the numerous novels dealing with the later revolutionary period are—*Les Blancs et les bleus* (3 vols., 1868) and *Les Compagnons de Jésus* (7 vols., 1857). *Les Louves de Mouchecoul* (10 vols., 1856) deals with the rising in 1832 in La Vendée. Other famous stories are—*Les Frères corses* (2 vols., 1845); *La Femme au collier de volours* (2 vols., 1851), *Les Mohicans de Paris* (19 vols., 1854-55), detective stories with which may be classed the series of *Crimes célèbres* (8 vols., 1839-41), which are, however, of doubtful authorship, *La San Felice* (9 vols., 1864-65), in which Lady Hamilton played a prominent part, with its sequels *Emma Lyonna* and *Souvenirs d'une favorite*. Of his numerous historical works other than fiction the most important is his *Louis XIV et son siècle* (4 vols., 1845). *Mes Mémoires* (20 vols., 1852-54, Eng. trans. of selections by A. F. Davidson, 2 vols., 1891) is an account of his father and of his own life down to 1832. There are collective editions of his plays: 16 vols., 1834-36, and 15 vols., 1861-74, but of the 91 pieces

for which he was wholly or partially responsible, 24 do not appear in these collections.

The complete works of Dumas were issued by Michel Lévy frères in 277 vols. (1860-84). The more important novels have been frequently translated into English. There is a long list of writings on his life and his works both in English and French. The more important French authorities are his own memoirs, already cited, C. Ginel, *Alexandre Dumas et son oeuvre* (Reims, 1884), H. Pargot, *Dumas père* (Grands écrivains français series, 1902), and *Le Drame d'Alexandre Dumas* (1899), H. Blaze de Bury, *Alexandre Dumas* (1885), Philibert Andebrand, *Alexandre Dumas à la maison d'or* (1888), G. Ferry, *Précis des œuvres d'Alexandre Dumas* (1882), and I. H. Lecomte, *Alexandre Dumas* (1904). Of the English lives of Dumas perhaps the best is that by Arthur F. Davidson, *Alexandre Dumas Père his Life and Works* (1902, bibl.). See the lives by P. Fitzgerald (1873) and H. A. Spurr (1902), and essays by Andrew Lang (*Letters to Dead Authors*) and R. L. Stevenson (*Memoirs and Portraits*). See also Herbert Gorman, *The Incredible Marquis Alexandre Dumas* (1929).

DUMAS, ALEXANDRE ("DUMAS FILS") (1824-1895), French dramatist and novelist, was born in Paris on July 27, 1824, the natural son of Alexandre Dumas (see above) and the dress maker Marie Labay. "Happily," writes the son, "my mother was a good woman, and worked hard to bring me up", while of his father he says, "by a most lucky chance he happened to be well-natured," and "as soon as his first successes as a dramatist" enabled him to do so, "recognized me and gave me his name." Nevertheless, the lad's earlier school-life was made bitter by his illegitimacy. The cruel taunts and malevolence of his companions ranked through life (see preface to *La Femme de Claude* and *L'Affaire Clémenceau*), and left indelible marks on his character and thoughts. Nor was his paternity, however distinguished, with out peril. Alexandre the younger and elder saw life together very thoroughly, and Paris can have had few mysteries for them. Surely the son, who had been led to regard his prodigal father's resources as inexhaustible, was rudely undeceived. Coffers were empty, and he had accumulated debts to the amount of £2,000.

Thereupon he pulled himself together. To a son of Dumas the use of the pen came naturally. Like most clever young writers—and report speaks of him as specially brilliant at that time—he opened with a book of verse, *Pêchés de jeunesse* (1847). It was succeeded in 1848 by a novel, *La Dame aux camélias*, a sort of reflection of the world in which he had been living. The book was followed, in fairly quick succession, by *Le Roman d'une femme* (1848) and *Diane de Lys* (1851). All this, however, did not deliver him from the load of debt, which, as he tells us, remained odious. In 1849 he dramatized *La Dame aux camélias*, but the rigour of the censorship and other circumstances delayed its production until Feb. 2, 1852, when Napoleon's all-powerful minister, Morny, intervened. The play succeeded then, and has held the stage ever since, less perhaps from inherent superiority to other plays which have foundered than to the great opportunities it affords to any actress of genius.

Thenceforward Dumas's career was that of a brilliant and prosperous dramatist. *Diane de Lys* (1853), *Le Demi-Monde* (1855), *La Question d'argent* (1857), *Le Fils naturel* (1858), *Le Père prodigue* (1859) followed rapidly. Debts became a thing of the past, and Dumas a wealthy man. The didactic habit was always strong upon him. "Alexandre loves preaching overmuch," wrote his father, and in most of his plays he assumes the attitude of a rigid and uncompromising moralist commissioned to impart to a heedless world lessons of deep import. The lessons themselves are mostly concerned with the "eternal feminine," by which Dumas was haunted, and differ in ethical value. Thus in *Les Idées de Madame Aubray* (1867) he inculcates the duty of the seducer to marry the woman he has seduced, but in *La Femme de Claude* (1873) he argues the right of the husband to take the law into his own hand and kill the wife who is unfaithful and worthless—so theses again defended in his novel, *L'Affaire Clémenceau*, and in his pamphlet, *L'Homme femme*, while in *Diane de Lys* he had taught that the betrayed husband was entitled to kill—not in a duel, but summarily—the man who had taken his honour, and in *L'Étrangère* (1876) the bad husband is the victim. Nor did he preach only in his plays. He preached in voluminous introductions, and pamphlets not a few. And when, in 1870 and 1872,

France was going through bitter hours of humiliation, he called her to repentance and amendments in a *Nouvelle Lettre de Junius* and two *Lettres sur les choses du jour*.

As a moralist Dumas *fit* took himself very seriously indeed. As a dramatist, didacticism apart, he had great gifts. He knew his business thoroughly, possessed the art of situation, interest, crisis—could create characters that were real and alive. His dialogue also is admirable, the repartee rapid like, the wit most keen. He was singularly happy, too, in his dramatic interpreters. The cast of *L'Etrangère*, for instance, comprised Sarah Bernhardt, Sophie Croizette, Madeleine Brohan, in the female characters, and Coquelin, Got, Mounet Sully and Febvre in the male characters, and Aimée Desclée, whom he discovered, gave her genius to the creation of the parts of the heroine in *Une Visite de noces*, the *Princesse Georges* and *La Femme de Claude*. He possessed wit in abundance, of a singularly trenchant kind. It shows itself less in his novels, which, however do not contain his best work, but in his introductions, whether to his own books or those of his friends, and what may be called his "occasional" writings, there is an admirable brightness. His style is that of the best French traditions.

Towards his father Dumas acted a kind of brother's part, and while keeping free from his literary influence, both loved and admired him. The father never belonged to the French Academy. The son was elected on Jan. 30, 1874. He died on Nov. 27, 1895. See J. Claretie, *A Dumas fils* (1883), P. Bourget, *Nouveaux Essais de psychologie contemporaine* (1885), "La Comédie de mort," by René Doumic, in *Le Petit de Juvénile de l'histoire de la langue et de la littérature française*, viii pp. 82 et seq., R. Doumic, *Portraits d'écrivains* (1892), Emile Zola, *Documentaires littéraires, études et portraits* (1888). (F. T. M.)

DUMAS, GUILLAUME MATHIEU, COUNT (1753-1837), French general, was born at Montpeller on Nov. 23, 1753, and entered the army in 1773. He served in America and elsewhere almost continuously up to the outbreak of the Revolution. During the Revolution he acted with the moderate party, and, though he was president of the Legislative Assembly in 1791, spent most of his time abroad until the consulate. Under Napoleon he served at Austerlitz, and then with Joseph Bonaparte in Naples and Spain. He was made a count of the empire in 1810. In 1812 he was intendant-general of the Grande Armée in Russia, but was taken prisoner after the capitulation of Dresden in 1813. At the first restoration he assisted in army administration, but joined Napoleon during the Hundred Days, when he organized the National Guard. He employed his enforced retirement after the second restoration in writing his *Précis des événements militaires* (19 vols., 1817-26), the first part of which had appeared anonymously at Hamburg in 1800. The *Précis* embraces the history of the war from 1798 to the peace of 1807. A growing weakness of sight, ending in blindness, prevented him from carrying the work further, but he translated Napier's *Penninsular War* as a sort of continuation of it. In 1818 Dumas was admitted a member of the council of state, from which, however, he was excluded in 1822. After the revolution of 1830, in which he took an active part, Dumas was created a peer of France, and re-entered the council of state. He died in Paris on Oct. 16, 1837.

Besides the *Précis des événements militaires*, which forms a valuable source for the history of the period, Dumas wrote *Souvenirs du lieutenant-général Comte Mathieu Dumas* (published posthumously by his son, 1839).

DUMAS, JEAN BAPTISTE ANDRÉ (1800-1884), French chemist, was born at Alais (Gard) on July 16, 1800. He wished to become an artist, but was apprenticed to an apothecary in his native town. In 1816 he moved to Geneva where he likewise was connected with a pharmacy. There he attended the lectures of Raoul Pictet (physics), Charles de la Rive (chemistry) and Augustin Pyramde de Candolle (botany).

Before he was 21 he was engaged with Dr. J. L. Prévost in original work on problems of physiological chemistry, and even of embryology. In 1823 Baron Alexander von Humboldt induced him to go to Paris, which he made his home for the rest of his life. He became a member of the national legislative assembly in 1849. He acted as minister of agriculture and commerce for a few months in 1850-51, and subsequently became a senator,

president of the municipal council of Paris and master of the French mint. His official career came to a sudden end with the fall of the Second Empire. He died at Cannes on April 11, 1884. He was buried with great ceremony in the Montparnasse cemetery in Paris. A statue was erected at his birthplace in 1899.

Dumas is a great figure in the chemical history of the middle part of the 19th century. He was one of the first to criticize the electrochemical doctrines of Jöns Jakob Berzelius (*qv*), which at the time his work began were widely accepted as the true theory of the constitution of compound bodies, and opposed a unitary view to the dualistic conception of the Swedish chemist. In a paper on the atomic theory (1816) he anticipated ideas which were frequently supposed to belong to a later period. The continuation of these studies led him to the ideas about substitution ("metalepsis") which were developed about 1839 into the theory ("Older Type Theory") that in organic chemistry there are certain types which remain unchanged even when their hydrogen is replaced by an equivalent quantity of a haloid element. Many of his researches were carried out in support of these views, one of the most important being that on the action of chlorine on acetic acid to form trichloroacetic acid—a derivative of essentially the same character as the acetic acid itself. In the 1816 paper he described his method for ascertaining vapour densities over wide temperatures, and the redeterminations which he undertook, by its aid and of the atomic weights of carbon and oxygen proved the forerunners of a long series which included some 30 of the elements, the results being mostly published in 1858-60. He devised a combustion method of great value in the quantitative analysis of organic substances for the estimation of nitrogen, while the classification of organic compounds into homologous series was advanced as one consequence of his researches into the acids generated by the oxidation of the alcohols.

Dumas was a prolific writer and his numerous books, essays, memorial addresses, etc., are written in a clear and graceful style. His earliest large work was a treatise (3 vols., 1828-48) on applied chemistry. His *Leçons sur la Philosophie chimique* in which he traced the development of chemistry from the earliest times was received with acclaim. In the *Essai de statique chimique des êtres organiques* (1841), written with Jean Baptiste Boussingault (1802-87), he treated the chemistry of life, both plant and animal. This book brought him into conflict with Raoul Justus von Liebig (*qv*), who contended that some of his prior work had been appropriated without due acknowledgment. In 1824, in conjunction with Jean V. Audouin and Adolphe Théodore Brongniart, Dumas founded the *Annales des sciences naturelles*, and from 1840 he was one of the editors of the *Annales de chimie et de physique*. As a teacher Dumas was the first French chemist to adopt the practical laboratory teaching method of Liebig, and in 1825 he used this method at the École Polytechnique and afterwards in his own laboratory. He succeeded Joseph Louis Gay Lussac at the Sorbonne. A member of the Académie des Sciences from 1832, he became its perpetual secretary in 1868, and was elected to the French academy in 1875 to the chair left vacant by the death of Guizot. See E. Thorpe, *Essays in Historical Chemistry* (1911), A. W. Hofmann, *Erinnerungen an vorangegangene Freunde* (1886), E. Maquard, *L'Œuvre de J. B. Dumas* (1886), W. H. Perkin, *Journal Chemical Society* (London, 1885).

DU MAURIER, GEORGE LOUIS PALMELLA-BUSON (1834-1896), British artist and writer, was born in Paris. His father, a naturalized British subject, was the son of *émigrés* who had left France during the Reign of Terror and settled in London. In *Peter Ibbetson*, the first of the three books which won George Du Maurier late in life a reputation as novelist almost as great as he had enjoyed as artist and humorist for more than a generation, the author tells in the form of fiction the story of his singularly happy childhood which was mostly spent at Passy. After some years at a Paris school, he left (in 1851) to study chemistry at University College, London, actually setting up as an analytical chemist afterwards in Bucklersbury. But this was clearly not to be his *métier*, and the year 1856 found him once more in Paris, in the Quartier Latin this time, in the core of that art world of which in *Tribby*, 40 years later, he was to produce with pen and pencil so idealistic and fascinating a picture. Then (like Barty Josselin in *The Martian*, his third novel) he spent some years in Belgium and the Netherlands, experiencing at Antwerp in 1857, when he was working in the studio of van Leru, the one great misfortune of his life—the gradual loss of sight in his left eye, accompanied by alarming symptoms in his right. It was a period of tragic anxiety, but the cloud was soon to show its silver lining, for, about Christmas time 1858, there came to the forlorn invalid a copy of *Punch's Almanac*, and with it the dawn of a new era in his career.

There can be little doubt that the study of this *Almanac*, and especially of Leech's drawings in it, fired him with the ambition to

of making his name as a graphic humorist, and it was not long after his return to London in 1860 that he sent in his first contribution (very much in Leech's manner) to *Punch*. Mark Lemon, then editor, appreciated his talent, and on Leech's death in 1865 appointed him his successor, counselling him with wise discrimination not to try to be 'too funny,' but "to undertake the light and graceful business" and be the "romantic tenor" in Mr. Punch's little company, while Keene, as Du Maurier puts it, "with his magnificent highly trained basso, sang the comic songs." These respective roles the two artists continued to play until the end, and Du Maurier himself in his book on *Social Pictorial Satire* has set forth their points both of resemblance and of difference. Besides working for *Punch* he illustrated several books, including his own novels, and from time to time he sent pretty and graceful pictures to the exhibitions of the Royal Society of Painters in Water Colour, to which he was elected in 1881. In 1885 the first exhibition of his works at the Fine Art Society took place. He died on October 8, 1896, and was buried in the Hampstead parish churchyard. He left a family of two sons—the elder, Major Guy Du Maurier (1865-1915), a soldier who became more widely known in 1909 as author of the military play *An Englishman's Home*, and the second, Gerald (later, Sir), a well known actor—and three daughters.

See *Thomas Armstrong C.B., a Memoir* (1912) and T. Martin Wood, *George Du Maurier* (1913). Other volumes containing information about Du Maurier's life and work are: M. H. Spielmann, *The History of Punch*, Felix Moscheles, *In Bohemia with Du Maurier* (1893), *Harper's Magazine* (Sept. 1897, June 1899). See also Ruskin, *Art of England*, Lecture 5, Pennell, *Pen Drawing and Pen-Draughtsmen*, and Muther, *Modern Painting*. (F. W. W.)

DUMBARTON, a royal, large and parliamentary burgh, seaport, and the county town, Dumbartonshire, Scotland, on the river Leven, near its confluence with the Clyde, 15½ mi. N.W. of Glasgow by the L.N.E.R. and L.M.S.R. Pop. (1938) 22,214. The Acluth ("hill of the Clyde") of the Britons, and Dumbreath ("fort of the Britons") of the Celts, it was the capital of the district of Strathclyde. Here the Romans had a naval station called Theodosia. The history of the town, however, practically centres in that of the successive fortresses on the Rock of Dumbarton, a twin peaked hill, 240 ft. high and a mile in circumference at the base. The Picts seized it in 736, the Northmen in 870, and Thomas Crawford of Jordanhill on March 31, 1571, in the interests of James VI. The castle has been held by Queen Mary's adherents, and gave them free communication with France. William Wallace was in 1305 imprisoned in the castle before he was removed to London. The higher of the two peaks is known as Wallace's seat, a tower being named after him. On the portcullis gateway are rudely carved heads of Wallace and his betrayer Queen Mary, when a child, residing in the castle for a short time. The rock is basalt, with a tendency to columnar formation.

Dumbarton was of old the capital of the earldom of Lennox, but was given up by Earl Maldwyn to Alexander II, by whom it was made a royal burgh in 1221 and declared to be free from all imposts and burgh taxes. Later sovereigns gave it other privileges, and all were finally confirmed by a charter of James VI. It had the right to levy customs and dues on all vessels on the Clyde between Loch Long and the Kelvin. "Offers dues" on foreign ships entering the Clyde were also exacted. In 1700 these rights were transferred to Glasgow by contract, but were afterwards vested in a special trust created by acts of parliament.

Most of the town lies on the left bank of the Leven, but there is communication with the suburb of Bridgend on the right bank by a five-arched stone bridge. Dumbarton is controlled by provost and council. It unites with Clydebank in returning one member to parliament. The principal industry is shipbuilding. The old staple trade of the making of crown glass, begun in 1777, lapsed some 70 years afterwards when the glass duty was abolished. There are several great engineering works, besides iron foundries, breweries, and rope-yards. There are quays, docks and a harbour at the mouth of the Leven, and a pier for river steamers runs out from the Castle rock, but is now disused. The first steam navigation company was established in Dumbarton in 1815, when the "Duke of Wellington" (built in the town) plied between Dumbarton and

Glasgow. But it was not till 1844, consequent on the use of iron for vessels, that shipbuilding became the leading industry.

DUMBARTONSHIRE, western county, Scotland, bounded north by Perthshire, east by Stirlingshire, south east by Lanarkshire, south by the Clyde and its estuary, and west by Loch Long and Argyllshire. The detached parish of Kirkintilloch and part of that of Cumbernauld are enclosed between the shires of Stirling and Lanark. This formerly formed part of Stirlingshire, but was annexed in the 14th century when the earl of Wigtown, to whom it belonged, became heritable sheriff of Dumbartonshire. Dumbartonshire has a land area (excluding water) of 244 sq. mi. The north west and west are mountainous, the highest point exceeding 3,200 feet. This is a district of rocks belonging to the metamorphic series of the Highlands, into which, in the north of the county, there is a large plutonic intrusion. In the south of the county are the Kilpatrick Hills (1,300 ft.), a system of lavas, tufts and agglomerates intercalated in the Calciferous Sandstone series. Sandstones of various ages occupy most of the rest of the county, but the Carboniferous limestone follows them in some parts, and notably in the detached portion of the county, includes important coal measures. The boulder clay of the Carboniferous lowland is full of schistose boulders brought by glacial action from areas far to the north west. The Clyde, the Kelvin and the Leven are the only rivers of importance. The Leven flows out of Loch Lomond at Balloch and joins the Clyde at Dumbarton after a serpentine course of about 7 miles. Most of the other streams are among the mountains, whence they find their way to Loch Lomond, and nearly all afford good fishing. Of the inland lakes by far the largest is Loch Lomond (q.v.). The boundary between the shires of Dumbarton and Stirling runs through the lake from the mouth of Endrick Water to a point opposite the Isle of Vow, giving about two thirds of the loch to the former county. Loch Sloy on the side of Ben Vorlich is a long, narrow lake, 812 ft. above the sea and wild scenery. From its name the Macfarlanes took their slogan or war cry. The shores of the Gareloch, a salt water inlet 6½ mi. long and 1 m. wide, are studded with houses of those whose business lies in Glasgow. Garelochhead, and Cove and Kilcreggan at the entrance to Loch Long, are favourite summer resorts. The more important salt water inlet, Loch Long, is 17 m. in length and varies in width from 2 m. at its mouth to about ½ m. in its upper reach. It is a dumping place for the dredgers which are constantly at work preserving the tide way of the Clyde from Dumbarton to Broomielaw. The scenery on both shores is very beautiful. Only a mile separates Garelochhead from Loch Long, and at Arrochar the distance from Tarbet on Loch Lomond is barely 14 miles. Nearly all the glens are situated in the Highland part of the shire, the principal being Glen Sloy, Glen Douglas, Glen Luss and Glen Fruin. The last is memorable as the scene of the conflict in 1603 between the Macgregors and the Colquhouns, in which the latter were almost exterminated. It was this encounter that led to the proscription of the Macgregors, including Rob Roy.

History—Prehistoric peoples have left rude forts and tumuli, and there are several remains of the wall of Antoninus, built from Forth to Clyde, and running along the north of the detached portion of the shire and through the south eastern corner of the county to Kilpatrick. Other Roman relics have been found at Duntocher, Cumbernauld and elsewhere. The shire forms part of the old Scottish territory of Lennox (*Levenachs*, "fields of the Leven"), which embraced the Vale of the Leven and the basin of Loch Lomond, or all modern Dumbartonshire, most of Stirling and parts of the shires of Renfrew and Perth. It gave the title of the earldom created in 1174 by William the Lion and of the dukedom conferred by Charles II. on his natural son, Charles, duke of Richmond and Lennox. Robert Bruce is said to have mustered his forces at Dullatur prior to the battle of Bannockburn, and died at Cardross Castle in 1329. The Covenanters in their flight from the field of Kilsyth, where in 1645 Montrose had defeated them, made their way through the southern districts. The clans of Macgregor and Macfarlane made their home in the Highland fastness and raided their Lowland neighbours.

Agriculture, Industries and Communications—The arable

lands extend chiefly along the Clyde and the Leven, and are composed of rich black loam, gravelly soil and clay. The farmers have markets on the Clyde for all kinds of stock and produce, and high farming and dairying prosper. Black faced sheep and Highland cattle are pastured on the hilly lands and Cheviots and Ayreshires on the low grounds. Oats is the principal crop (5,514 ac. in 1938), potatoes, turnips, swedes and some wheat are also grown. The average size of the 662 holdings in 1938 was 64½ ac. but 57% were 50 ac. or less.

Turkey red dyeing has long been a distinctive industry. The water of the Leven being singularly soft and pure, dyers and bleachers have constructed works at many places. Bleaching has been carried on since the early part of the 18th century, and cotton printing at Levenfield dates from 1768. There are large establishments at Alexandria, Bonhill, Jamestown, Renton and other towns for bleaching, dyeing and printing of cottons, calicoes and other cloths, besides yarns. The engineering works and ship building yards at Clydebank are famous, and at Dumbarton there are others. Coal and freestone are worked, and sandstone and igneous rocks are quarried in the detached position at Kirkintilloch and Cumbernauld.

The populous districts of the county are served by the LNER from Helensburgh to Invermanan. The West Highland line runs through beautiful scenery. The LMSR has access to Balloch from Glasgow and traverses the detached portion. Portions of the Forth and Clyde canal, connecting with the Clyde at Bowling, and opened for traffic in 1775, pass through the shire. There is regular steamer communication between Glasgow and the towns and villages on the coast.

Population and Government.—Pop. (est. 1938) 155,243. In 1931 Gaelic and English were spoken by 1,874 persons. The principal towns are Clydebank (est. 1938 pop. 47,912), Dumbarton (22,214), a royal burgh and both large burghs, the small burghs of Helensburgh (8,743), Kirkintilloch (12,845) and Milngavie (6,278), and Bonhill (1931 pop. 15,565). The fourth small burgh is Cove and Kilcraggan. There are six county districts. The county returns one member to parliament, and Dumbarton, the county town, one member with Clydebank. Dumbartonshire forms a sheriffdom with the counties of Stirling and Clackmannan, and there is a resident sheriff substitute at Helensburgh, who sits also at Dumbarton and Kirkintilloch.

DUMB WAITER, originally a small oblong or circular table to hold reserve plates, knives and forks, and other necessities for a meal. It came into use in England towards the end of the 18th century, and some elegant examples were designed by Sheraton and his school. They were usually circular, with three diminishing tiers, sometimes surrounded by a continuous or interrupted pierced gallery in wood or brass. Smaller varieties are much used in England for the display of small silver objects in drawing-rooms. The term was more recently extended to mean the small elevator used to convey household commodities from one floor to another in modern apartments. It is a box like structure, about 2 ft. square, built within the walls, and run with a rope and pulley.

DUM-DUM, a town and cantonment in British India, in the district of the Twenty-four Parganas, 4½ mi. N.E. of Calcutta. The name is derived from *dam dama*, meaning a raised mound, a battery. It was the headquarters of the Bengal artillery 1783–1853, when they were transferred to Meerut. It has an army Nile and ammunition factory. The town is divided between two municipalities, North Dum-Dum (pop. 1941, 5,974) and South Dum-Dum (pop. 1941, 25,838). It was at Dum-Dum that Siraj-ud-daula signed the treaty of 1757 with Clive.

At the Dum Dum foundry the hollow nosed "Dum-Dum" (Mark IV) bullets were manufactured, the supposed use of which by the British during the Boer War caused considerable comment in 1899. Their peculiarity consisted in their expanding on impact and thus creating an ugly wound, and they had been adopted in Indian frontier fighting owing to the failure of the usual type of bullets to stop the rushes of fanatical tribesmen. They were not, in fact, used during the Boer War. Other and improved forms of expanding bullet were used in India and the Sudan, the commonest methods of securing expansion being to file down

the point until the lead core was exposed and to make longitudinal slots in the nickel envelope. All these forms of bullet have come to be described colloquially, and even in diplomatic correspondence, as "dum dum bullets" and their alleged use by Russian troops in the Russo-Japanese War of 1904–05 formed the subject of a protest on the part of the Japanese government. An International declaration was made at the second Hague conference, July 29, 1899, forbidding the use of these bullets. The United States did not participate in this declaration. During World War I actual charges were made by the belligerents of the use of illegal bullets, but there was no evidence forthcoming that such use (if any) was authorized by any power.

DUMESNIL, MARIE FRANÇOISE (1713–1803), French actress, whose real name was Marchand, was born in Paris on Jan. 2, 1713, made her debut in 1737 at the Comédie Française as Clytemnestre in *Iphigénie en Tauride*. She played Cleopatra, Phedre, Athalie and Hermione with great effect, and when she created Merope (1743), Voltaire says that she kept the audience in tears for three successive acts. She retired in 1776 and died on Feb. 20, 1803. She authorized the publication of a *Mémoire de Marie Françoise Dumesnil*, in reply to an attack by her rival, Clairon (1800).

DUMFRIES, a royal and large burgh and the county town, Dumfriesshire, Scotland (Gaelic, "the fort in the cope"). It lies on the left bank of the Nith, about 8 mi. from the Solway Firth and 82 mi. S.E. of Glasgow by the LMSR, and is a junction for several lines. Pop. (1938) 23,797. Dumfries is a fine town, beautifully situated. St. Michael's (1746) was the church which Robert Burns attended, and in its churchyard he was buried, his remains being transferred in 1815 to the magnificent mausoleum erected in the southeast corner. The schools include an important academy. In the middle of the market place stands the old town hall, with red tower and cupola, known from its situation as the Mid Steeple. It was built by Tobias Bachup of Alloa (1708) and is now occupied by shops. The Theatre Royal, reconstructed in 1876, dates from 1787. Burns composed several prologues and epilogues for some of its actors and actresses. The Nith is crossed by three bridges and the railway viaduct. The bridge used for vehicular traffic dates from 1790–1794. Devorguilla's bridge below it, built of stone in 1280, originally consisted of nine arches (now reduced to six) and is reserved in spite of its massive appearance for foot passengers only, as is also the suspension bridge opened in 1875.

Muxwellton, on the opposite side of the river, was amalgamated with Dumfries as from Nov. 1929. It is of modern growth and has an observatory. The leading industries comprise manufactures of tweeds, hosiery, gloves and neckties, besides the timber trade, dye works and nursery gardening. Dumfries markets for horses, cattle and sheep have always ranked with the best, and there is also a market for pork during the five months beginning with November. Dumfries was long the leading market for hare skins, being still important in this respect. The Nith is navigable at Dumfries for vessels drawing 8 ft., but the sea-borne trade is small.

Although Dumfries was the site of a camp of the Selgovian Britons, nothing is known of its early history. William the Lion (d. 1214) made it a royal burgh, but the oldest existing charter was granted by Robert II. in 1395. The town became embroiled in the struggles that ended in the independence of Scotland. It favoured the claims to the throne, first of John Balliol—whose mother Devorguilla, daughter of Alan, lord of Galloway, had done much to promote its prosperity by building the stone bridge over the Nith—and then of the Red Comyn, as against those of Robert Bruce, who drew his support from Annandale. Until nearly the close of the 16th century the burgh was exposed to frequent raids, both from freebooters on the English side and from partisans of the Douglases, Maxwells and Johnstones. James VI. was royally entertained on Aug. 3, 1617, and afterwards presented the seven incorporated trades with a silver gun to encourage craftsmen in the practice of musketry. A competition for this gun, which is now kept in the old town hall, took place annually—with a great festival every seven years—until 1831. John Mayne (1759–1836), a native of Dumfries, commemorated

the gathering in a humorous poem, "The Siller Gun" The Union with England was so unpopular that not only did the provost vote against the measure in the Scottish parliament, but the articles were burned (Nov. 20, 1706) at the Market Cross by a body of Cameronians. In both 1715 and 1745 Dumfries remained apathetic. Burns, the poet, resided here from December 1791 till his death on the 21st of July 1796. The house in which he died is still standing.

The picturesque ruins of Carlarverock Castle, which is claimed to be the 'Ellangowan' of *Guy Rannering*, are 8 mi. to the south. Part of the present structure is believed to date from 1220 and once sheltered William Wallace. It withstood Edward I's siege in 1300 for two days, although garrisoned by only sixty men. Subsequently it often changed hands. In 1570 it fell into disrepair, but was restored, and in 1641 was besieged for the last time by the Covenanters. A mile and a half to the northwest of Dumfries lies Lancluden Abbey, 'an old ruin,' says Burns, "in a sweet situation at the confluence of the Cluden and the Nith." Originally the abbey was a convent, founded in the 12th century, but converted two centuries later into a collegiate church by Archibald, earl of Douglas. The remains of the choir and south transept disclose rich Decorated work.

DUMFRIESSHIRE, border county, Scotland, bounded south by Solway Firth, south east by Cumberland, east by Roxburghshire, north by the shires of Lanark Peebles and Selkirk and west by Ayrshire and Kirkcudbrightshire. Area (excluding water) is 1,073 sq mi. The county slopes gradually from uplands of 2,000 ft in the north down to the sea, loftily hills alternating in places with stretches of tableland or rich fertile holms. The greater part belongs to the tableland of Salurnian rock in southern Scotland, which is bordered in the north west and south of the county by old red sandstones, and broken at many points by intensive igneous rocks. Strata of Carboniferous age (among others) occur in hollows of the tableland, and at Sanquhar and Rowanburn include coal measures, which have been worked but are no longer rich. At various points within a few miles of the Solway are tracts of moss land, like Craigs Moss, Lochar Moss and Longbridge Moor in the west, and Nuthery Moss in the east, all once under water, but now largely reclaimed. The county is cleft from north to south by Nithsdale, Annandale and Eskdale. The Nith (65 m) enters the shire 16 m from its source and flows south east to the Solway. The Annan rises near the Devil's Beef Tub, a remarkable chasm in the far north, and flows south for about 40 m to the Solway. From the confluence of the White Esk (rising near Ettrick Pen) and the Black Esk (rising near Jock's Shoulder, 1,754 ft) the Esk flows south east to the border, and south-west in Cumberland to the Solway. For 1 m of its course the Esk, and for 7 m of its course the Sark, form the boundaries between Dumfriesshire and Cumberland. Loch Skene in the north (1,750 ft above sea), the group of lochs around Lochmaben, and Loch Urr in the west, are the principal lakes. The wild and beautiful passes of Dalveen, Enterkin and Menock, lead up from Nithsdale to the Lowther and other hills. For part of the way Enterkin pass runs between mountains rising sheer from the burn to a height of nearly 2,000 feet. Loch Skene finds an outlet in Tail burn, the water of which at a short distance from the lake leaps from a height of 200 ft in a fine waterfall known as the Grey Mare's Tail. A much-rarer fall but picture-que fall of the same name, also known as Cichopee fall, occurs on the Cichopee, near Thornhill. Mineral waters are found at Fionia, Hartfall Spa, some three miles farther north, and Closeburn on the Solway.

History—The early populations have left hill forts in the hills, stone circles (as in Dumfries and Liddell, Liddell, Liddell, Dryfessdale), tumuli and cairns (Clochburn), and sculptured stones (Dornock). The country around Norri appears to be rich in remains. At Holmwood, near Dumfries, there stands the relic of the grove of sacred oaks from which the place derived its name, and a stone circle known locally as the Twelve Apostles. The British inhabitants were called Selgovae by the Romans. In the parish church of Ruthwell (prov. Ravel the road on which, well) is preserved an ancient cross which tells in Runic char-

acters the story of the Crucifixion. There are traces of Roman roads which ran by Dalveen pass into Clydesdale and up the Annan to Tweeddale, and at Birrens is a well preserved Roman camp. Roman altars, pottery and coins have been found in many places. Upon the withdrawal of the Romans, the Selgovae were conquered by Scots from Ireland. The Saxon conquest of Dumfriesshire does not seem to have been thorough, the people of Nithsdale and elsewhere maintaining their Celtic institutions up to the time of David I.

Edward I besieged Carlarverock castle, and the factions of Bruce (who was lord of Annandale), John Comyn and John Baliol were at constant feud. The Border clans were always at strife until the 18th century. The hill country afforded retreat to persecuted Covenanters, who, at Sanquhar, published in 1680, their declaration against the king, anticipating the principles of the "glorious Revolution" by several years. The Jacobite sentiment made little appeal to the people.

Robert Burns firmed at Ellisland on the Nith for three years, and spent the last five years of his life at Dumfries. Thomas Carlyle was born at Ecclefechan, in a house still standing, and was buried beside his parents in the kirkyard.

Agriculture, Industries and Communications—Towards the middle of the 18th century farmers began to raise stock for the south, and 100 years later 20,000 head of heavy cattle, for merly Galloways, later mostly shorthorns and Ayrshires, were sent annually to the English markets. In 1938 there were 83,528 cattle in the county. Sheep breeding, of later origin, has attained to large dimensions (612,622 in 1938), the walks in the higher hilly country being given over to Cheviots, and the richer pasture of the low lying farms being reserved for half bred lambs, a cross of Cheviots and Leicesters or other long-wooled rams. Horse-breeding is pursued on a considerable scale. Oats is easily the largest crop, with 30,145 ac in 1938, followed by turnips and swedes with 11,826 ac. Half the 2,691 holdings were of 50 ac or less, though the average holding was 89½ ac. Sheep, cattle, pigs, grain, wool, hides and skins are exported. Some lead ore is mined, and limestone and sandstone are quarried. In general, the manufactures are only of local importance, the chief being the woollen and hosiery industries of Dumfries and Langholm. There are distilleries at Langholm and Annan, dyeing and tanning works at Langholm. Nursery gardening and some shipping are carried on at Annan and Dumfries, and the salmon fisheries of the Nith and Annan and the Solway Firth are of value.

Of the two main lines of the L.M.S.R. between Glasgow and Carlisle, one (the former Glasgow and South Western), runs through Nithsdale, practically following the course of the river, and lower Annandale to the Border. The other (the former Caledonian railway) runs through Annandale, throwing off at Beattock a branch to Moffat, at Lockerbie a cross-country line to Dumfries, and at Kirtlebridge a line to Annan. From Dumfries westwards there is communication with Castle Douglas, Kirkcudbright, Newton Stewart, Stranraer and Portpatrick. The L.N.E.R. sends a short line to Langholm from Riddings Junction in Cumberland, giving access to Carlisle and, by the Waverley route, to Edinburgh.

Population and Government—The population was estimated in 1928 at 81,818. In 1921 Gaelic and English were spoken by 214 persons. The chief towns are Dumfries, a large burgh (est. 1938 pop. 23,797), the small burghs of Annan (1,916), Langholm (1,385), Lockerbie (1,640) and Moffat (1,950). There are nine county districts. The county returns one member to parliament. Dumfries, the county town, Annan, Lochmaben and Sanquhar, the last two being small burghs, are '1st' burghs, Dumfries forms a sheriffdom with the shires of Kirkcudbright and Wigton, and there is a resident sheriff-substitute at Dumfries. Secondary education has been notably directed by public authorities toward carving on science and technical classes, embracing agriculture and dairying (at Kilmarnock dairy school). There are technical schools at Dumfries, Annan, Moffat and other centres.

DUMICHEN, JOHANNES (1833-1894), German Egyptologist was born near Grosslogau. He studied philology and theology in Berlin and Breslau, and in 1872 became professor of Egyptian at Strasbourg. In 1875-76 he directed the excavation of the temple at Dendera.

Among his works are *Baukunde des Tempels von Dendera* (1865), *Geographie der Inschriften ägyptischer Denkmäler* (4 vols., 1865-84), *Ägyptische Kalendarischkeiten* (1865), *Ägyptische Tempelschriften* (2 vols., 1867), *Historische Inschriften ägyptischer*

Denkmäler (2 vols, 1867-1869), *Baugeschichte und Beschreibung des Denderatempels* (Straussburg, 1877), *Die Oasen der libyschen Wüste* (1878), *Die kalendrischen Opferfesten von Medinet Habu* (1881), *Gesch. des alten Aegypten* (1878-1883), *Der Grabpalast des Psammetichus in der thebanischen Nekropolis* (1884-1894)

DUMKA (pl Dumky), a Little Russian term signifying a lament and employed frequently by Dvorak in his chamber works to designate movements of a melancholy, mournful character. The English word "dumpp," signifying a melancholy mood, and also a doleful ditty, is possibly akin. Cf also Ger *dumppf*, meaning dull, flat, dead

DUMMLER, ERNST LUDWIG (1830-1902), German historian, the son of Ferdinand Dummier (1777-1846), a Berlin bookseller, was born in Berlin, on Jan 2, 1830. He studied at Bonn under J. W. Lobell (1766-1863), under L. von Ranke and W. Wattenbach. He entered the faculty at Halle in 1855, became professor extraordinary (1858), and full professor (1866). In 1875 he became a member of the revised committee directing the *Monumenta Germaniae historica*, himself undertaking the direction of the section *Antiquitates*, and in 1888 became president of the central board in Berlin. His great work was the *Geschichte des ostfränkischen Reiches* (1862-65, in 2 vols., 2nd ed 1887-88, in 3 vols.) In conjunction with Wattenbach he completed the *Monumenta Alamanica* (1873), which had been begun by Philipp Jaffe, and with R. Kopke he wrote *Kaiser Otto der Grosse* (Leipzig, 1876). He edited the first and second volumes of the *Poetae latini aevi Carolini* for the *Monumenta Germaniae historica* (1881-84). Dummier died in Berlin on Sept 11, 1902.

DUMMY, in advertising and printing, a material representation or full sized complete physical model showing the general appearance of a proposed folder, pamphlet, or other piece of printing. It is used as a guide both in sketching in the details of the various pages and in assisting the printer to follow instructions as to how the work is to appear when finished.

DUMONT, the name of a family of prominent French artists. François Dumont (1688-1726), a sculptor, best known for his figures in the church of Saint Sulpice, Paris, was the brother of the painter Jacques Dumont, known as "le Romain" (1701-1781), whose chief success was gained with a great allegorical composition for the Paris *Hôtel de Ville* in 1761. François' son Edme (1720-1775), the latter's son Jacques Edme (1761-1844), and the son of the last named, Augustin Alexander (1801-1884), were also famous sculptors. A contemporary, Jean Joseph Dumons (1687-1770), sometimes called Dumont, is best known for his designs for the Aubusson tapestries.

See G. Vattier, *Une Famille d'artistes* (1890).

DUMONT, ANDRÉ HUBERT (1809-1857), Belgian geologist, was born at Liège on Feb 15, 1809. He was professor of mineralogy and geology and afterwards rector in the university of Liège. He spent 20 years on the preparation of a geological map of Belgium (1849), and then collected materials for a geological map of Europe. The Geological Society of London awarded him the Wollaston medal in 1840, and he died at Liège on Feb 28, 1857.

See Memoir by Major-General J. E. Portlock in *Address to Geol Soc* (1858).

DUMONT, FRANÇOIS (1751-1831), French miniature painter, was born at Luneville (Meurthe), studied for a time under Jean Girardet, and in 1788 was accepted as an academician and granted an apartment in the Louvre. He married the daughter of Antoine Vestier, the miniature painter, and had two sons, Aristide and Bias, both of whom became painters. He was one of the three greatest miniature painters of France, painting portraits of Louis XVI and Marie Antoinette, Louis XVIII and Charles X, and of almost all the important persons of his day. His own portrait was engraved both by Audouin and by Tardieu. He spent the greater part of his life in Paris, and there he died. A younger brother, known as Tony Dumont, was also a miniature painter, a pupil of his brother, a frequent exhibitor and the recipient of a medal from the Academy in 1810. Each artist signed with the surname only, and there is some controversy concerning the attribution to each of his own canvases. Many of Dumont's finest

paintings came into the collection of J. Pierpont Morgan, but others are in the Louvre, presented by the heir of Bias Dumont.

See G. C. Williamson, *The History of Portrait Miniatures* (1904), also the privately printed *Catalogue of the Collection of Miniatures of Mr J. Pierpont Morgan*, vol IV.

DUMONT, JEAN (d 1726), French publicist, became his toriographer to the emperor, who conferred on him the title of baron de Carlescoen. He died at Vienna in 1726, at an advanced age.

Among his publications are—*Mémoires politiques pour servir à la parfaite intelligence de l'histoire de la Paix de Ryswick* (The Hague, 1699, 4 vols 1700), *Recherches modestes des causes de la présente guerre, en ce qui concerne les Provinces Unies* (1713, 12mo), *Recueil de traités depuis la Paix de Münster* (Amsterdam, 1710, 2 vols 12mo), *Corps universel diplomatique du droit des gens, contenant un recueil des traités de paix, d'alliance, etc., faits en Europe, depuis Charlemagne jusqu'à présent* (Amsterdam, 1696, and following years, 8 vols fol, continued after Dumont's death by J. Rousselet), and *Batailles gagnées par le Prince Eugène de Savoie* (The Hague, 1723). Dumont was also the author of *Lettres historiques contenant ce qui se passe de plus important en Europe* (12mo). This periodical, which was commenced in 1692, two volumes appearing annually, Dumont conducted till 1710, from which time it was continued by Basnage and others until 1728. The earlier volumes are much prized.

DUMONT, PIERRE ETIENNE LOUIS (1759-1829), French political writer, was born at Geneva where his family had been citizens of good repute from the days of Calvin. He was educated for the ministry at the college of Geneva, and in 1781 was chosen one of the pastors of the city. The triumph of the austro-catholic party in 1782, however, through the interference of the courts of France and Sardinia, made residence in his native town impossible, though he was not among the number of the proscribed. He therefore went to join his mother and sisters at St Petersburg (Leningrad). In 1785 Lord Shelburne took him to London as tutor to his sons. There he met Fox, Sheridan, Lord Holland and Sir S. Romilly.

In 1788 Dumont visited Paris with Romilly. During a stay of two months in that city he met Mirabeau with whom he became intimate. On his return from Paris Dumont made the acquaintance of Jeremy Bentham, and set himself to recast and edit the writings of the great English jurist in a form suitable for the ordinary reading public. This literary relationship was, according to Dumont's own account, one of a somewhat peculiar character. All the fundamental ideas and most of the illustrative material were supplied in the manuscripts of Bentham, Dumont's task was chiefly to abridge by striking out repeated matter, to supply lacunae, to secure uniformity of style, and to improve the French. The following works of Bentham were published under his editorship: *Traité de législation civile et pénale* (1802), *Théorie des peines et des récompenses* (1811), *Traité des assemblées législatives* (1815), *Traité des preuves judiciaires* (1823), and *De l'organisation judiciaire et de la codification* (1828).

In the summer of 1789 Dumont went to Paris. He contributed to Mirabeau's journal, the *Courier de Provence*, supplying it with reports as well as original articles, and also furnishing Mirabeau with speeches to be delivered or rather read in the assembly, as related in his posthumous work entitled *Souvenirs sur Mirabeau* (1832).

In 1814 the restoration of Geneva to independence induced Dumont to return to his native place, and he soon became the leader of the supreme council. Many improvements in the judicial and penal systems of his native state are due to him.

See A. P. de Candolle, *Notice sur la vie et les écrits de M. Dumont* (1829).

DUMONT D'URVILLE, JULES SÉBASTIEN CESAR (1790-1842), French navigator, was born at Conde sur-Noireau, in Normandy. He went to sea in 1807 as a novice on board the "Aquilon." During the next 12 years he gradually rose in the service, and added a knowledge of botany, entomology, English, German, Spanish, Italian and even Hebrew and Greek to the professional handicrafts of his studies. In 1820, while engaged in a hydrographic survey of the Mediterranean, he was fortunate enough to recognize the Venus of Milo (Melos) in a Greek statue recently unearthed, and to secure its preservation by the report he

presented to the French ambassador at Constantinople. In 1822 he served in the circumnavigating expedition of the "Coquille" under the command of his friend Duperrey, and on its return in 1825 he was promoted *capitaine de frégate*, and given the command of a similar enterprise, with the purpose of discovering traces of the lost explorer, La Perouse, in which he was successful. The "Astrolabe" as he renamed the "Coquille," left Toulon on April 25, 1826, and returned to Marseille on March 25, 1829, having traversed the south Atlantic, coasted the Australian continent from King George's sound to Port Jackson, charted various parts of New Zealand, and visited the Fiji islands, the Loyalty islands, New Caledonia, New Guinea, Amboyna, Van Diemen's Land, the Caroline islands, Celebes and Mauritius. Promotion to the rank of *capitaine de vaisseau* was bestowed on the commander in Aug. 1829, and in August of the following year he conveyed the exiled king Charles X. to England. On Sept. 7, 1837, he set sail from Toulon with the "Astrolabe" and its convoy "La Zélée" on a voyage of exploration in the South Polar regions. On Jan. 15, 1838, they sighted the Antarctic ice, and soon after their progress southward was blocked by a continuous bank, which they vainly coasted for 3000 m. to the east. Returning westward they visited the South Orkney islands and part of the New Shetlands, and discovered Joinville island and Louis Philippe Land, but were compelled by scurvy to seek succour at Talcahuano in Chile. Thence they proceeded across the Pacific and through the Asiatic archipelago, visiting among others the Fiji and the Pelew islands, coasting New Guinea, and circumnavigating Borneo. In 1840, leaving their sick at Hobart Town, Tasmania, they returned to the Antarctic region, and subsequently discovered Adèle Land, which D'Urville named after his wife, in 140° E. Nov. 6 found them at Toulon. On May 8, 1842, D'Urville was killed, with his wife and son, in a railway accident near Meudon. An island (also called Kairu) off the north coast of New Guinea and a cape on the same coast bear his name.

His principal works are—*Enumeratio plantarum quas in insulis Archipelagi aut interibus Pontis Euxini, etc.* (1822), *Voyage de la corvette "l'Astrolabe" 1826–1829* (1830–35), *Voyage du pôle sud et dans l'Océanie 1837–1840* (1842–54), in each of which his scientific colleagues had a share, *Voyages autour du monde, résumé général des voyages de Magellan, etc.* (1833 and 1844).

DUMORTIERITE, a mineral first recorded from pegmatite in gneiss at Chaponost, near Lyons, France, and named after E. Dumortier, a French palaeontologist. It is essentially a basic aluminum borosilicate, most reliable analyses conforming to the formula $8Al_2O_3 \cdot 6SiO_2 \cdot B_2O_3 \cdot H_2O$. Crystallizing in the rhombic system, it occurs usually in fibrous or columnar aggregates of blue, lavender or almost black colour. These commonly observed colours are due to the oxides of iron and titanium always present in small amounts. The mineral is strongly pleochroic in blue and violet tints. On heating to 800° C the colour rapidly disappears. At higher temperatures B_2O_3 is volatilized and decomposition occurs with formation of mullite ($3Al_2O_3 \cdot 2SiO_2$), liquid appearing first at a temperature of 1,550°C.

On account of its high alumina content dumortierite possesses considerable advantages as a basis for refractory bodies. Dumortierite occurs as a rare constituent of pegmatites and gneisses. The best known locality is at Clip, Ariz., where it is found as dense fibres embedded in quartz. Among European localities its presence in pegmatite at Eilon (Scotland), in cordierite-gneiss at Tvedestrand (Norway), with corundum in pegmatite at Wolf shan (Silesia) may be mentioned. In company with lazulite and kyanite it occurs in quartzites at Chari (French Central Africa) and Svarbia (Madagascar). (C. E. T.)

DUMOULIN, CHARLES (MOLINAEUS) (1500–1566), French jurist, was born in Paris in 1500. He began practice as an advocate before the parlement of Paris. Dumoulin turned Calvinist, and when the persecution of the Protestants began he went to Germany, where for a long time he taught law at Strasburg, Besançon and elsewhere. He returned to France in 1557. Dumoulin had, in 1552, written *Commentarii sur l'édit du roi Henri II sur les petites dates*, which was condemned by the Sorbonne, but his *Conseil sur le fait du concile de Trente* created a still greater stir, and aroused against him both the Catholics and

the Calvinists. He was imprisoned by order of the parlement until 1564. Dumoulin was regarded by his contemporaries as the "prince of jurisconsults." He had a considerable effect on the subsequent development of French law. He was a bitter enemy of feudalism, which he attacked in his *De feudis* (Paris, 1539). Other important works were his commentaries on the customs of Paris (Paris, 1539, 1554, Frankfurt, 1575, Lausanne, 1576), valuable as the only commentary on those in force in 1510, and the *Extracato labyrinthi dudum et individui*, a treatise on the law of surety.

A collected edition of Dumoulin's works was published in Paris in 1681, with a life by Brodeau. See also H. de Pansey, *Éloge de C. Dumoulin* (1769), Hello, *Essai sur la vie et les Ouvrages de C. Dumoulin* (1839).

DUMOURIEZ, CHARLES FRANÇOIS DU PERIER (1739–1823), French general, born at Cambrai on Jan. 25, 1739, saw his first service as a volunteer in the campaign of Rossbach. He was retired at the peace of 1763, but was subsequently employed in Corsica. Under Choiseul he was in the secret service, and on his patron's fall was imprisoned, being only released on the accession of Louis XVI. in 1774. Dumouriez was commandant of Cherbourg for ten years, and in 1788 became *maréchal de camp*. At the outbreak of the Revolution he went to Paris, where he joined the Jacobin Club. The death of Mirabeau, to whose fortunes he had attached himself, was a great blow to him, but, promoted to the rank of lieutenant general and commandant of Nantes, his opportunity came after the flight to Varennes, when he offered to march to the assistance of the Assembly. He now joined the Girondist party, and on March 15, 1792, was appointed minister of foreign affairs. He was munificently responsible for the declaration of war against Austria (April 20), and the invasion of the Low Countries was planned by him. On the dismissal of Roland, Clavière and Servan (June 13), he took the latter's post of minister of war, but resigned it two days later on account of the king's refusal to come to terms with the Assembly, and went to join the army of Marshal Luckner. After the *émée* of August 10 and Lafayette's flight he was appointed to the command of the "Army of the Centre," and at the same moment the Coalition assumed the offensive. Dumouriez acted promptly. His subordinate Kellermann repulsed the Prussians at Valmy (Sept. 20, 1792), and he himself severely defeated the Austrians at Jemappes (Nov. 6).

Defeated at Neerwinden in Mar. 1793, he ventured all on a desperate stroke. Arresting the commissaires of the Convention sent to inquire into his conduct, he handed them over to the enemy, and then attempted to persuade his troops to march on Paris and overthrow the revolutionary government. The attempt failed, and Dumouriez with the duc de Chartres (afterwards King Louis Philippe) and his brother the duc de Montpensier, fled into the Austrian camp.

In 1804 he settled in England, where the government conferred on him a pension of £1200 a year. He became a valuable adviser to the War Office in connection with the struggle with Napoleon, though the extent to which this was only known to the public many years later. He died at Turville Park, near Henley on Thames, on March 14, 1823. His memoirs were published at Hamburg in 1794. An enlarged edition, *La Vie et les mémoires du Général Dumouriez*, appeared at Paris in 1823.

See A. von Boguslawski, *Das Leben des Generals Dumouriez* (1878–79), *Revue des deux mondes* (July 15, Aug. 1 and 15, 1884), H. Weichinger, *Le Roman de Dumouriez* (1890), J. A. Chuquet, *La Première Invasion, Valmy, La Retraite de Brunsvich, Jemappes, La Trahison de Dumouriez* (1886–91), A. Sorci, *L'Europe et la Révolution française* (1885–92), J. Holland Rose and A. M. Broadley, *Dumouriez and the Defence of England* (1908), E. Daudet, *La Conspiration de Pichegru et les complots royalistes du midi et du nord, 1795–1797* (1901), Pouget de Saint-André, in his *Le Général Dumouriez* (1914) contends that Dumouriez has been misjudged.

DUMP (1) (Of obscure origin), a state of wonder, perplexity or melancholy. The word thus occurs particularly in the plural, in such phrases as "doleful dumps." It was also formerly used for a tune, especially one of a mournful kind. (2) (Connected with "dump," but appearing later than that word, and also of obscure origin), something short and thick, and hence used of many objects such as a lead counter or medal, of a coin formerly used in

powerless Mackensen's army swept over the shattered trenches of the X Corps, meeting with little resistance, and pressed forward in the direction of Rzeszow and Jaroslaw. The Austrian IV Army forced the Russian IX Corps from its line on the lower Dunajec. The Austrian II and III Armies in the Carpathians also began a forward move. There followed five days of hard fighting, but the Russians were unable to stem the tide. Radko Dimitriev's reserve corps attacked gallantly but fruitlessly, his left wing had to yield the Dukla pass and the hard-won gains of the April offensive. An attempt to stand on the line of the Wistok river and the Lupków pass failed before renewed Austro-German attacks on May 8. Brusilov's VIII Army was now also involved in the retreat, and a few days later the left wing of the Russian IV Army north of the Vistula retired from the line of the Nida.

The Russians now decided to check their foes on the strong line of the river San, with the fortress of Przemyśl to support their left centre, and the Dniester marshes to protect their left flank. Mackensen's army, however, reached Jaroslaw on May 14, stormed the bridge-head next day and established itself east of the San. It extended its gains to Sieniawa on the following days and threatened to jeopardize the whole Russian position on the San. But the impetus of the attack had spent itself for the moment and the Russians were given a breathing space. Strong reinforcements were being hurried up to them, but their losses had been enormous, over 170,000 in prisoners alone.

Further Austro-German Attacks.—The second stage of the fighting began with an attack by Mackensen's forces on May 24, which forced the line of the San at and about Radymno and thrust southeast towards the Przemyśl-Lemberg railway. The Austrians simultaneously attacked Przemyśl from the south, but made little progress. The Russians now made a counter stroke on Sieniawa, north of Jaroslaw, with the III Caucasian Corps. This gallant corps stormed the Austrian positions and caused a temporary set back to Mackensen's plans. At the same time heavy attacks were made on the Austrian IV Army further north.

But the odds against the Russians were too heavy, they had little or no ammunition for their guns and practically no heavy artillery at all. Before combined attacks of the German XI and Austrian II and III Armies, Przemyśl fell on June 3, and the line here had to be withdrawn to about Grodek. The line of the lower San, north of Sieniawa, was held till June 11, when Mackensen, who had received reinforcements, attacked again and forced the whole of the San line, the Russians retiring to the last line of defence west of Lemberg. (See LEMBERG, BATTLES OF.)

By the middle of June the Russian losses in Galicia since the beginning of Mackensen's offensive included nearly 400,000 prisoners, over 300 guns and much other material. Their losses in killed and wounded had also been exceedingly heavy, for they had counter-attacked repeatedly with little artillery support. The Russians were in fact paying in flesh and blood for their lack of modern equipment. The dominance of his heavy artillery was the chief factor in Mackensen's success; the Russians had none with which to oppose it. (See WORLD WAR I.)

DUNASH, the name of two Jewish scholars of the 10th century.

1. **DUNASH BEN LABRAT**, grammarian and poet, belonged to the brilliant circle attracted to Cordova by Hasdai, and took a large share in promoting the Jewish "Golden Age" under the Moors in Andalusia. Dunash not only helped in the foundation of a school of scientific philology, but adapted Arabian metres to Hebrew verse, and thereby gave an impulse to the neo-Hebraic poetry, which reached its highest level in Spain.

2. **DUNASH IBN TAMIM** was, like the preceding, a leader in the critical study of language among Arabic-speaking Jews. Professor Bachner says of him: "In the history of Hebrew philology Ibn

Tamim ranks as one of the first representatives of the systematic comparison of Hebrew and Arabic."

DUNBAR, GEORGE (1774-1851), English classical scholar and lexicographer, was born at Coldingham, in Berwickshire. When about 30 years of age, he settled in Edinburgh, where he became tutor in the family of Lord Provost Fettes. In 1807 he succeeded Andrew Dalziel as professor of Greek in the university, and held the post till his death. His Greek-English and English-Greek lexicon (1840), on the compilation of which he spent eight years, was the best work of its kind that had appeared in England.

The little that is known of Dunbar's life will be found in the *Caledonian Mercury* (Dec. 8, 1851).

DUNBAR, PAUL LAURENCE (1872-1906), American author, of negro descent, was born in Dayton (O.), June 27, 1872. In high school he wrote the class poem and was editor-in-chief of the school paper. While earning his living as an elevator boy, assistant in the library of Congress, etc., he continued to write, recite, and publish his work, and after 1898, the year of his marriage, he gave his full time to writing. He died of consumption at his home in Dayton, Feb. 8, 1906. His poetry was brought to the attention of American readers by William Dean Howells, who reviewed *Majors and Minors* (1896) in *Harper's Weekly* and wrote an appreciative introduction to his *Lyrics of Lowly Life* (1896), which was subsequently used in his *Complete Poems* (1913). Dunbar published numerous volumes of verse, novels and short stories. Some of his short stories and sketches, especially those dealing with the American negro, are charming, they are far superior to his novels, which deal with scenes in which the author is not so much at home. His most enduring work, however, is his poetry. Some of this is in literary English, but the best is in the dialect of his people.

See L. K. Wiggins, *Life and Works of Paul Laurence Dunbar* (Naperville (Ill.), 1907). Tributes to him by his wife, Alice Moore Dunbar, also a writer, and by others, were reprinted from the *A. M. E. Church Review* under the title *Paul Laurence Dunbar, Poet Laureate of the Negro Race*.

DUNBAR, WILLIAM (c. 1460-c. 1520), Scottish poet. He became M.A. at St Andrews in 1479 and afterwards joined the Order of Observantines Franciscans, at St Andrews or Edinburgh, proceeding to France as a wandering friar. He spent a few years in Picardy, and was still abroad when, in 1491, Bothwell's mission to secure a bride for the young James IV reached the French court. About 1500 he returned to Scotland, and became a priest at court, and a royal pensioner. His literary life begins with his attachment to James' household. He is spoken of as the rhymist of Scotland in the accounts of the English Privy Council dealing with the visit of the mission for the hand of Margaret Tudor, rather because he wrote a poem in praise of London than because, as has been stated, he held the post of laureate at the Scottish court. In 1511 he accompanied the queen to Aberdeen and commemorated her visit in verse. Other pieces, such as the *Orison* ("Queen the Gouverneur past in France"), apropos of the setting out of the regent Albany, are of historical interest, but they tell us little more than that Dunbar was alive.

One hundred and one poems have been ascribed to Dunbar. Of these at least 90 are generally accepted as his of the 11 attributed to him it would be hard to say that they should not be considered authentic. Most doubt has clung to his verse tale *The Peiris of Berwik*.

Dunbar's chief allegorical poems are *The Goldyn Targe* and *The Thrissil and the Rous*. The motif of the former is the poet's futile endeavour, in a dream, to ward off the arrows of Dame Beautee by Reason's "schild of gold." When wounded and made prisoner, he discovers the true beauty of the lady when she leaves him, he is handed over to Heaviness. The noise of the ship's guns, as the company sails off, wakes the poet to the real pleasures of a May morning. Dunbar works on the same theme in a shorter poem, known as *Beautee and the Prisoner*. *The Thrissil and the Rous* is a prothalamium in honour of James IV and Margaret Tudor, in which the heraldic allegory is based on the familiar beast-parliament.

The greater part of Dunbar's work is occasional—personal and

social satire, complaints (in the style familiar in the minor verse of Chaucer's English successors), orisons, and pieces of a humorist character. The last type shows Dunbar at his best, and points the difference between him and Chaucer. The best specimens of this work, of which the outstanding characteristics are sheer whimsicality and topsy-turvy humour, is *The Ballad of Kynd Kittok*. This strain runs throughout many of the occasional poems, and is not wanting in odd passages in Dunbar's contemporaries, and it has the additional interest of showing a direct historical relationship with the work of later Scottish poets, and chiefly with that of Robert Burns. Dunbar's satire is never the gentle funning of Chaucer: more often it becomes invective. Examples of this type are *The Satire on Edinburgh*, *The General Satire*, the *Epitaph on Donald Owre*, and the powerful vision of *The Dance of the Seven Duddie Symms*. In the *Flying of Dunbar and Kennedy*, an outstanding specimen of a favourite northern form, analogous to the continental *estrif*, or *tenson*, he and his rival reach a height of scurrility which is certainly without parallel in English literature. This poem has the additional interest of showing the racial antipathy between the "Ingils"-speaking inhabitants of the Lothians and the "Scots" or Gaelic speaking folk of the west country.

There is little in Dunbar which may be called lyrical, and little of the dramatic. His *Interlude of the Droschis* (*Dwarf's part of the Play*), one of the pieces attributed to him, is supposed to be a fragment of a dramatic composition. It is more interesting as evidence of his turn for whimsicality, already referred to, and may for that reason be safely ascribed to his pen. If further selection be made from the large body of miscellaneous poems, the comic poem on the physician, Andro Kennedy, may stand out as one of the best contributions to mediaeval Goliardic literature, *The Two Marrit Women and the Wedo*, as one of the richest and most effective *pastiches* in the older alliterative style, then used by the Scottish Chaucerians for burlesque purposes, *Done is a battell on the Dragon Blak*, for religious feeling expressed in melodious verse, and the well known *Lament for the Makaris*. The main value of the last is historical, but it, too, shows Dunbar's mastery of form, even when dealing with lists of poetic predecessors.

BIBLIOGRAPHY—The chief authorities for the text of Dunbar's poems are—(a) the Asloan ms (c 1515), (b) the Chepman and Myllar prints (1568), preserved in the Advocates' library, Edinburgh, (c) Bannatyne ms (1568) in the same, (d) the Matland Folio ms

are caught. There are few industries, but corn, fish and potatoes are exported.

A castle was built on the cliffs at least as early as 856. In 1070 Malcolm Canmore gave it to Cospatrick, earl of Northumberland, ancestor of the earls of Dunbar and March. The fortress was an important bulwark against English invasion, and the town—which was created a royal burgh by David II—grew up under its protection. The castle was taken by Edward I, and it afforded shelter to Edward II after Bannockburn. In 1336 it was besieged by the English under William, Lord Montacute, afterwards 1st earl of Salisbury, but was successfully defended by Black Agnes of Dunbar, countess of March, a member of the Murray family. Joanna Beaufort, widow of James I, chose it for her residence, and in 1479, after his escape from Edinburgh Castle, the duke of Albany concealed himself here before sailing for France, and Mary sheltered here in two crises. The regent Moray dismantled it in 1568, but its ruins are still a picturesque object on the hill above the harbour.

Battle of Dunbar—This battle was fought on the 3rd (13th) of September 1650 between the English army under Oliver Cromwell and the Scots under David Leslie, afterwards Lord Newark. It took place about 3m SE of the centre of the town, where between the hills and the sea coast there is a plain about 1m wide, through the middle of which the main road from Dunbar to Berwick runs. The plain and the road are crossed at right angles by the course of the Brocks Burn, or Spott Burn, which at first separated the hostile armies. Rising from the right bank of the Brock is Doon Hill (560ft.), which overlooks the lower course of the stream and indeed the whole field. For the events preceding the battle see GREAT REBELLION.

Cromwell, after a war of manoeuvre near Edinburgh, had been compelled by want of supplies to withdraw to Dunbar, Leslie pursued and took up a position on Doon Hill, commanding the English line of retreat on Berwick. The situation was more than difficult for Cromwell. Some officers were for withdrawing by sea, but the general chose to hold his ground, though his army was enfeebled by sickness and would have to fight on unfavourable terrain against odds of two to one. Leslie, however, who was himself in difficulties on his post among the bare hills, and was perhaps subjected to pressure from civil authorities, descended from the heights on Sept. 2 and began to edge towards his right, in order first to confront, and afterwards to surround,

BATTLE OF DUNBAR SEPT. 3 1650
Oliver Cromwell with a force of 11,000 men defeated the Scots under David Leslie in one of the most complete victories of the Great Rebellion. The Scottish commander had been drawn into leaving his stand on Doon Hill for a position on the plains where Brocks Burn divided his army. Cromwell instantly seized this opportunity for a surprise stroke.

his opponent. The cavalry of his left wing stood fast, west of Doon Hill, as a pivot of manoeuvre, the northern face of Doon (where the ground rises from the burn at an average slope of fifteen degrees and is even steeper near the summit) he left unoccupied. The centre of infantry stood on the forward slope of the long spur which runs east from Doon, and beyond them, practically on the plain, was the bulk of the Scottish cavalry. But if Leslie had placed himself on Cromwell's line of retreat, he had thereby placed Cromwell on his—to the latter's moral advantage. In the evening Cromwell drew up his army, under 11,000 effective

men, along the ravine, and issued orders to attack the Scots at dawn of the 3rd (13th). The left of the Scots was ineffective, as was a part of their centre of foot on the upper part of the hillside, and the English commander proposed to deal with the remainder. Before dawn the English advanced troops crossed the ravine, attacked Doon and punned Leslie's left, under cover of this the whole army began its manoeuvre. The artillery was posted on the Dunbar side of the burn, directly opposite and north of Doon, the infantry and cavalry crossed where they could, and

of the poems), appeared in 1894.

DUNBAR, a royal and small burgh (Gaelic, "the fort on the point"), and seaport, East Lothian, Scotland Pop (est 1938) 3,827. Area, 1.1 sq mi. It is on the southern shore of the entrance to the Firth of Forth, 2½ mi NE of Edinburgh by the LNER. Dunbar is said to have the smallest rainfall in Scotland and is a favourite summer resort, with good golf and bathing. The ruins of the castle, and the remains of the Grey Friars' monastery, founded in 1218, at the west end of the town, and Dunbar House in High street, formerly a mansion of the Lauderdales, but now used as barracks, are of historic interest.

There are two harbours, difficult of access owing to the number of reefs and sunken rocks. On the advent of steam the shipping declined, and even the herring fishery, which fostered a large curing trade, has now practically disappeared. Crabs and lobsters

formed up gradually in a line south of and roughly parallel to the Berwick road, the extreme left of horse and foot, acting as a reserve, crossed at Brocks-mouth House on the outer flank. The Scots were surprised in their hurrahs, but quickly formed up, and at first repulsed both the horse and the foot. But ere long Cromwell himself arrived with his reserve, and the whole English line advanced again. The Irish impulse enabled it to break the Scottish cavalry and repulse the foot, and Leslie's line of battle was gradually rolled up from right to left. In the words of an English officer, "The sun appearing upon the sea, I heard Noli say, 'Now let God arise, and let His enemies be scattered,' and following us as we slowly marched I heard him say, 'I profess they run.'" Driven into the broken ground, and panned between Doon Hill and the ravine, the Scots were indeed helpless. "They routed one another after we had done their work on their right wing," says the same officer. Ten thousand men, including almost the whole of the Scottish foot, surrendered, and their killed numbered three thousand. Few of the English were killed. "I do not believe," wrote Cromwell, "that we have lost twenty men."

The account of the battle of Dunbar here followed is that of C. H. Porth for which see his *Cromwell*, pp. 281 ff. and references there given. For other accounts see Carville, *Cromwell's Letters and Speeches*, letter cd; Hoernig, *Cromwell*; Balldoc, *Cromwell as a Soldier*; and Gardiner, *Hist. of the Commonwealth and Protectorate*, vol. 1.

DUNBLANE, a small burgh and parish, Perthshire, Scotland, on the left bank of Allan water, a tributary of the Forth, 5 mi. N.W. of Stirling by the L.M.S.R. Pop. (1938) 2,762. It is a place of great antiquity, with narrow streets and old fashioned houses. Industry is limited, but a considerable amount of worsted spinning is carried on, the town is in repute as a watering place. The cathedral, by the side of the river, was one of the few ecclesiastical edifices that escaped injury at the hands of the Reformers. The first church is alleged to have been erected by Blane, a saint of the 7th century, but the cathedral was founded by David I. in 1141, and almost entirely rebuilt about 1240 by Bishop Clemens. The tower is Early Norman, the rest is Early Pointed style. After the decline of episcopacy the building was neglected for a long period, but the choir, which contains some carved oak stalls of the 16th century, and nave have been restored. From the time of the Reformation the choir only had been used as the parish church, but since its restoration the whole cathedral has been devoted to this purpose. An ancient Celtic cross, 64 ft. high, stands in the north-western corner of the nave. Of the bishop's palace only a few ruins remain. The Queen Victoria School for the sons of Scottish soldiers and sailors, to the north of Dunblane, was opened in 1908, and the chapel in the grounds in 1910. The battle-field of Sheriffmuir is about 2½ m. E. of the town.

DUNCAN, the name of two Scottish kings.

DUNCAN I. (d. 1040) was a son of Crinan or Cronan, lay abbot of Dunkeld, and became king of the Scots in succession to his maternal grandfather, Malcolm II, in 1034, having previously as *rex Cumbro-rum* ruled in Strathclyde. His accession was "the first example of inheritance of the Scottish throne in the direct line." Duncan is chiefly known through his connection with Macbeth, which has been immortalized by Shakespeare. The only fact which can be ascertained with any certainty about the feud between the two princes is that Duncan was slain by Macbeth in 1040. Two of Duncan's sons, Malcolm III. Canmore and Donald V. Bane, were afterwards kings of the Scots.

DUNCAN II. (d. 1094) was a son of Malcolm III. and therefore a grandson of Duncan I. For a time he lived as a hostage in England and became king of the Scots after driving out his uncle, Donald Bane, in 1093, an enterprise in which he was helped by some English and Norman troops. He was killed in the following year.

See W. J. Stone, *Chiefs of Scotland* (1876, 88), and A. Lane, *His. of Scotland*, vol. 1 (1890).

DUNCAN, ADAM DUNCAN, 1st Viscount (1735–1801). British naval commander, was born on July 17, 1735, at Lunenburg, Fortarburgh, Scotland. During the years 1756 he saw much active service in European and American waters and in Feb. 1795 he was appointed as commander in chief of the North Sea fleet appointed to his post the British navy. Towards the end of May 1797, though in consequence of the mutiny in

the British fleet, he had been left with only the "Adamant" (50), besides his own ship the "Venerable" (74). Admiral Duncan proceeded to his station off the Tewel, where lay at anchor the Dutch squadron of 15 sail of the line, under the command of Vice admiral de Winter. From time to time he caused signals to be made, as if to the main body of a fleet in the offing a stratagem which probably secured his freedom from molestation until, in the middle of June, reinforcements arrived. On Oct. 3 the admiral put into 3 armoured roads to refit, but receiving information early on the 6th that the enemy was at sea, he gave chase. On the morning of the 11th de Winter's fleet was sighted lying about 9 m. from shore, between the villages of Egmont and Camperdown. The British fleet was slightly superior in force to that of the Dutch. Shortly after mid day the British ships, without waiting to form in order, broke through the Dutch line, and an engagement commenced which, after heavy loss on both sides, resulted in the taking by the British of 11 of the enemy's vessels. In recognition of this victory, Admiral Duncan was, on Oct. 21, created Viscount Duncan of Camperdown and Baron of Lundie, with an annual pension of £3,000 to himself and the two next heirs to his title. The earldom of Camperdown was created for his son Robert (1785–1859) in 1831, and is still in the possession of his descendants. Lord Duncan retired in 1800, and died on Aug. 4, 1804. See Charnock, *Brit. Nav.* (1794–98); Collins, *Pearage of England*, p. 378 (1812); W. James, *Naval History of Great Britain* (1824); Yonge, *History of the British Navy*, vol. 2 (1863); Earl of Cardoux, *Admiral Duncan* (1898), vol. xvi of the Navy Record Soc. publications, contains the logs of the ships engaged at Camperdown.

DUNCAN, ISADORA (1878–1927), American dancer, was born at San Francisco (Calif.) on May 27, 1878. She began her career as a girl of 17 at Daly's theatre, New York, where she danced the part of a fairy in *A Midsummer Night's Dream*. Her early years were full of poverty and difficulty. With only the sum of \$150, the Duncans went to England in a cattle boat, and in London and Paris, before recognition was won, they nearly starved.

Isadora had already conceived the thought of interpretative dancing to awaken the world to the grace and meaning of nature dancing, spiritual expression flowing into the channels of the body. She spent hours studying the Greek vases in the Louvre. Then she danced in Paris, Budapest, Florence and Berlin. Later, amid the ruins of the Theatre of Dionysus in Athens, she meditated on the dances of Hellas. In that atmosphere she further worked out her ideas of the dance evolved directly from nature, through the rhythmic movement of wind and wave and the winged flight of bird and bee. Her ideas were so old that, to an over civilized world accustomed to the artificiality of the ballet and much dressed dramatic dancing, they were startlingly new. Even the Russian ballet through Michel Fokine at home and Sergei Diaghilev's *Ballets Russes* abroad was influenced by Isadora Duncan's ideas and technique after she visited St. Petersburg in 1905. In 1904 she established a school for classical dancing near Berlin, where she taught her art to girls who later became known as the Duncan dancers, another in Paris in 1914, and another in Moscow in 1921, which was closed in the spring of 1928. Isadora Duncan and her sister had a school near Tarrytown.

When she returned to her native country in 1908 the United States was puzzled and divided itself into enthusiasts and critics. But later the stage of the Metropolitan opera house itself was hers for her performances. In April 1915, with the dancers from her Paris school she danced for a month at the Century theatre, trying to interest Americans in a project for a school in her own land. One was conducted for a short time near Tarrytown, N.Y., by her sister, Elizabeth, who had much to do with the display of Isadora's genius. Conventionally minded people were estranged, however, by her erratic actions, which became more marked after an automobile tragedy in Paris, 1913, when her two children, Deirdre and Patrick, with their nurse were drowned.

She became an ardent advocate of the Soviet revolution in Russia and accepted Lenin's invitation (1921) to open the Moscow school of dancing in the palace of a former nobleman, which was given to her. Her marriage with a Russian, Sergei Essennin, ten years younger than herself, the difficulties at Ellis Island in 1922 on re entering the United States with him, the episode of the red

scaif waved during a performance on the stage of the Symphony Hall, Boston (Oct. 22, 1922), brought on her such trials that she left America vowing never to return.

The last years of her life were pitifully tragic—in debt and difficulty in Germany and France. Her many friends rallied to establish the Duncan memorial dance school at Neuilly, rousing in all 400,000 francs. She was killed in an automobile accident at Nice on Sept. 14, 1927. Her work to a certain extent was carried on by her adopted daughters, Anna and Irma who danced, and by Elizabeth Duncan who had a school near Salzburg.

See her autobiography *My Life* (1927), Shaemas O'Sheels 'Isadora,' *New Republic* (Oct. 6, 1927), Jose Clara's 'Isadora Duncan,' *Le 1er decembre* (1913), *Le Ballet Contemporain, ouvrage edite avec la collaboration de L. Bakst. Traduction française de M. D. Calvo-crespi et Svetlov*, pseud. of Valerian Yakovlevich Ivenchenko and Charles H. Caffin's 'Henry Matise and Isadora Duncan,' *Camera Work* (1909).

DUNCAN, JOHN (1796-1870), Scottish theologian and Hebrust, was born at Aberdeen and studied at Marischall college. In 1836 he was ordained in the Established Church and given charge of Milton church, Glasgow. After three years as a missionary to the Jews in Budapest he was appointed, in 1843, to the chair of Oriental languages in the new Free Church college, Edinburgh. Apart from his 1838 edition of Robinson's *Lexicon of the Greek New Testament*, Duncan's writings consist largely of sermons and addresses, some of which were edited by J. Steven Sinclair (1925). He died on Feb. 26, 1870.

See Knight, *Colloquia Peripatetica* (1870) and Brown, *The Late Rev. J. Duncan* (1874).

DUNCAN, ROBERT KENNEDY (1868-1914), American chemist, was born near Brantford, Ont., Canada on Nov. 1, 1868. He graduated at the University of Toronto in 1892, studied at Clark university and later at Columbia university (1897-98). He taught physics and chemistry in New York and Pennsylvania high schools. From 1901 to 1906 he was professor of chemistry at Washington and Jefferson college. During parts of 1903, 1904 and 1907, he made special studies in Europe. In 1906, while attending the International Congress of Applied Chemistry in Rome, he conceived the idea of the industrial fellowship system. His plan was to assist American manufacturers in making their products in a scientific manner and to base their plans for efficient production upon scientific research. In 1907 he became professor of industrial chemistry at the University of Kansas, and the same year arranged for the establishment of the first industrial fellowship. In 1910, his work at Kansas attracted attention in Pittsburgh, and he was made professor of chemistry at the University of Pittsburgh and director of industrial research, which position he held until his death on Feb. 18, 1914. In March 1913 the Mellon Institute of Industrial Research of the University of Pittsburgh was founded by Andrew W. Mellon and Richard B. Mellon of Pittsburgh as a memorial to their father, Thomas Mellon, and also to Duncan. This placed the industrial fellowship system upon a permanent basis.

Duncan's works are noted for their high scientific accuracy. Among his more important books are *The New Knowledge* (1905), *The Chemistry of Commerce* (1907), and *Some Chemical Problems of To-day* (1911).

DUNCAN, THOMAS (1807-1845), Scottish portrait and historical painter, was born at Kinclaven, Perthshire, on May 24, 1807, and died at Edinburgh, May 25, 1845. He was a pupil of Sir William Allan. His most famous pictures are "Prince Charles Edward and the Highlanders entering Edinburgh after the battle of Prestonpans" (1843) and "Charles Edward asleep after Culloden, protected by Flora MacDonald" (1843), which has often been engraved.

DUNCAN, a city of southern Oklahoma, U.S., on federal highway 81 and the Rock Island railroad, the county seat of Stephens county. The population was 15,260 in 1950 and was 9,207 in 1940 by the federal census. There is a diversified income from agriculture, dairying, produce, livestock and oil production.

Within a few miles of the city of Duncan, there are oil and gas wells, and the city has refineries and casinghead plants and whole

sale houses dealing in oil well supplies, as well as numerous jobbers in other lines. Duncan was settled about 1890 and incorporated in 1899. It has a well equipped airport.

DUNCE, a stupid person, incapable of learning. "Duns" or "dunsman" was a name applied by their opponents to the Scots or followers of Duns Scotus, the great schoolman. When, in the 16th century, the Scotists obstinately opposed the "new learning" the term "duns" or "dunce" became, in the mouths of the humanists and reformers, a term of abuse, a synonym for one incapable of scholarship.

DUNCKER, MAXIMILIAN WOLFGANG (1811-1886), German historian and politician, eldest son of the publisher Karl Duncker, was born at Berlin on Oct. 15, 1811. He studied at the universities of Bonn and Berlin till 1834, when he was condemned to six years' imprisonment afterwards reduced to six months, for belonging to students' societies. In 1842 he became a lecturer at Halle university. Elected to the National Assembly at Frankfurt in 1848, he joined the Right Centre party, and was chosen reporter of the projected constitution. He sat in the Erfurt assembly in 1850, and in the second Prussian chamber from 1849 to 1857. In 1859 he was assistant in the ministry of State in the Auerswald cabinet and in 1867 he became director of the Prussian archives, with which it was his task to incorporate those of Hanover, Hesse and Nassau. He retired on Jan. 1, 1875, and died at Ansbach on July 21, 1886. Duncker's fame rests mainly on his *Geschichte des Alterthums* (1st ed. 1855-57, 5th ed. in 9 vols., 1878-80, Eng. trans. by Evelyn Abbott, 1877-82).

His works include *Zur Geschichte der deutschen Reichsversammlung in Frankfurt* (1849), the anonymous *Vier Monate ausserlicher Politik* (1851), *Origines Germaniae* (1840), *Die Krisis der Reformation* (1845) and *Feudalismus und Aristokratie* (1858). See his *Politischer Briefwechsel* (ed. W. Schulze, 1923), and Harn, *Das Leben Max Duncckers* (1892).

DUNCOMBE, SIR CHARLES (c. 1648-1711), English politician, was a London apprentice, who became a goldsmith and a banker, and an alderman of the City of London in 1683. Duncombe was elected MP for Hedon in 1685 and afterwards sat for Yarmouth in the Isle of Wight and Downton in Wiltshire. He was made receiver of the customs, and for a short time receiver of the excise, and in this capacity he profited slightly by a transaction over some exchequer bills which had been falsely endorsed. Tried before the court of the king's bench in 1699 he was found "not guilty." He represented Downton a second time from 1702 until his death. In 1709 he served as lord mayor of London. He died at Teddington on April 9, 1711.

DUNDALK, a seaport of Co. Louth, Ireland, near the mouth of the Castletown river, in Dundalk bay. Pop. of urban district (1946) 18,562. It is an important junction on the G.N. railway, by which it is 54 mi. N. from Dublin. Dundalk was a borough by prescription, and received charters from Edward III. and successive kings. It was stormed in 1315 by Edward Bruce, who here proclaimed himself king. He was defeated and killed by the English in 1318 in the neighbourhood, and was buried at Faughart, near Dundalk. Ruins of a Franciscan priory with a lofty tower may still be seen. There are distilleries, breweries, flax and jute spinning mills, salt works, etc. The town is in large part dependent for its prosperity upon the activity of the Great Northern railway, which maintains large railway shops. There are also shoe factories. Trade is in agricultural produce and livestock. The town is also the centre of sea and salmon fisheries.

DUNDEE, JOHN GRAHAM OF CLAVERHOUSE, Viscount (c. 1649-1689), Scottish soldier, was the elder son of Sir William Graham and Lady Madeline Carnegie. Educated at St. Andrews university, he served as a volunteer in France and Holland, returning to England in 1677. In 1678 he became a lieutenant, and soon afterwards captain of a troop, in the regiment commanded by his relative, the marquis of Montrose, and was employed in suppressing the rebellion of the Covenanters.

After the murder of Archbishop Sharp (1679), there were reports of rebels gathering near Glasgow, and Graham went in pursuit. On June 1, the Covenanters being in a well protected position upon the marshy ground of Drumclog, Graham advanced to the attack. Hindered by the ground, he had to wait till the

the Spanish frigate 'Esmeralda' (40) in the harbour of Callao on Nov. 5, 1825 was a signal achievement. In 1834 he transferred his services to Brazil where he helped the emperor Dom Pedro I to shake off the yoke of Portugal, but by the end of 1835 he had fallen out with the Brazilians and he returned to Europe. He then entered the Greek service, but he found no opportunity for distinguishing himself, and in 1838 returned home. He succeeded in 1837 in securing reinstatement in the British navy. In 1848 he was appointed to the command of the North American and West India station, which he retained till 1851. At various periods of his life he occupied himself with scientific invention. He took out patents for lamps to burn oil of tar, for the propulsion of ships at sea, for facilitating excavation, mining and sinking, for rotary steam engines and for other purposes, and in 1843 was an advocate of the employment of steam and the screw propeller in warships. Lord Dundonald died in London on Oct. 30, 1860, and was buried in Westminster Abbey. He was succeeded in the title by his son Thomas as 11th earl (d. 1885), and the latter by his title Douglas as 11th earl (q.v.).

See the 10th earl's *Autobiography of a Seaman* (2 vols., 1860-61), which was the main source for his *Life* (1860, by his son and heir), his *Notes on the Mineralogy, Government and Condition of the British West India Islands* (1851), and a *Narrative of Services in the Liberation of Chile, Peru and Brazil* (1858), and J. B. Atlay, *The Trial of Lord Cochrane before Lord Ellenborough* (1897).

DUNDONALD, DOUGLAS MACKINNON BAILLIE HAMILTON COCHRANE, 12TH EARL OF (1852-1935), son of the 11th earl of Dundonald and Louisa Mackinnon, was born on Oct. 29, 1852, and succeeded to the earldom in 1885. On leaving Eton he entered the 2nd Life Guards, in 1870, and served in the Nile expedition of 1884-85, and in the desert march to the relief of Khartoum. In 1899-1900 he commanded the Mounted Brigade in South Natal, and led the 2nd Cavalry Brigade into Ladysmith in 1900. In the same year he was promoted major general. In 1907 he was made K.C.V.O. and in 1913 K.C.B.

DUNEDIN, a city of New Zealand, capital of the provincial district of Otago, and the seat of a bishop, in Taieri county. Pop. (1936) 64,708 (81,961 with suburbs). It lies 15 mi. from the open sea at the head of Otago harbour, a narrow inlet on the south-eastern coast of South Island.

The colony of Otago (from a native word meaning ochre, which was found here and highly prized by the Maoris) was founded as the chief town of the Otago settlement by settlers sent out under the auspices of the Free Church of Scotland in 1848. The discovery of large quantities of gold in Otago in 1861 and the following years brought prosperity, a great "rush" of diggers setting in from Australia.

The situation was chosen on the consideration of this harbour alone for the actual site offered many difficulties, steep forest-clad hills rising close to the sea, and rendering reclamation necessary. The hills give the town a beautiful appearance, as the forest was allowed to remain closely embracing it, being preserved in the public ground named the Town Belt. The principal thoroughfare is comprised in Prince's street and George street, running straight from south-west to north-east and passing through the Octagon, which is surrounded by several of the principal buildings. From these streets others strike at right angles down to the harbour, while others lead obliquely up towards the Belt, beyond which are extensive suburbs. The town hall, Athenaeum and museum are noteworthy buildings. The first having a fine biological collection. The University of Otago at Dunedin, a constituent college of the University of New Zealand, was founded in 1869, it has notable medical and dental schools and a school of mines.

DUNES or DUNKIRK DUNES, BATTLE OF, was fought near Dunkirk on May 24 (June 3), 1658, between the French and English army under the command of Marshal Turenne and the Spanish army under Don Juan of Austria and the prince of Condé. The severest part of the fighting was borne by the English contingents on either side. Six thousand English infantry under Gen. Lockhart were sent by Cromwell to join the army of Turenne, and several Royalist corps under the command of the duke of York (afterwards James II) served in the Spanish forces. The object of the Spaniards was to relieve Dunkirk, which Turenne was besieging. Don Juan had a strong superiority in cavalry, but left behind his artillery in order not to delay his advance. He took up a position on the dunes with his right on the sea and his left on the Bruges canal, and here Turenne at once attacked him. Condé's cavalry on the left wing charged with great resolution and despite heavy loss gained the upper hand. But their success was nullified by the failure of the Spanish right wing and centre under Turenne's pressure, to which Cromwell's veterans largely contributed. But when all the rest of the Spanish army was in rapid retreat the one small corps of English Royalists, some 300 strong only, held out stubbornly and only laid down their arms on terms that they were allowed to rejoin their king, Charles II, at Ypres. From this corps the Royal Regiment of Guards, as descended the present Grenadier Guards. With Turenne's victory, the surrender of Dunkirk speedily followed, and the fortress passed into English hands until sold back by Charles II—an ironical last word on this singular footnote to English history.

DUNES, mounds or hills and ridges of sand heaped by wind. They are numerous in (1) deserts, particularly in low lying areas, (2) on sandy coasts with onshore winds, and (3) near rivers of which the volume varies, leaving sandy beds exposed during the dry season. The *areg* of the Sahara and Arabian deserts are characterized by vast expanses of dunes, as are the *komus* of the deserts of Persia and Turkistan and the plateaux of Gobi and other Mongolian deserts. Few such desert dunes are found in America or Australia, but the sand hill region of western Nebraska affords a good illustration. The coasts of Brittany, Cornwall, the Landes of France, the shores of the Baltic in Europe, the whole eastern coast of North America from Cape Cod southward and at places along the Pacific coast, and numerous leeward coasts of Africa, Australia and Asia serve as examples of oceanic coastal dunes. Lacustrine dunes are admirably developed on the east shore of Lake Michigan, the south shores of Lake Superior and Lake Erie, the shores of former Lakes Lahontan and Bonneville in the Great basin of North America, and on the east shores of the Caspian and Aral seas in western Asia. Examples of river bank dunes are found in almost every land, as for instance along the east banks of the Mississippi, Missouri and Rio Grande rivers in the United States.

Dunes migrate constantly unless the sand of which they are composed is prevented from blowing by grass or other vegetation. The rate at which dunes move varies, depending upon the velocity of the wind and the height of the dunes, small dunes migrating the faster. In Denmark the rate is from 3 to 20 ft. a year, in France, on the Bay of Biscay, the sands have advanced at a rate estimated from 15 to 105 ft. a year, burying in their progress forests, farms, vineyards, churches and whole villages, some of which may in course of time be exhumed as the dunes migrate onward. On the south side of Lake Michigan forests which were buried by sand dunes have been uncovered as the dunes moved on. Hundreds perhaps thousands of square miles of towns and cities in central Asia are buried under dunes. Moving dunes constantly encroach upon the Suez canal. Nor are dunes merely a contemporary geologic feature. Sand dune deposits are recognizable by the character of their bedding in sandstone rocks of many geologic periods, indicating that aolian action has been prevalent throughout geologic history. Fossil dunes are widely distributed. See DOWNS.

(W. E. E.)

DUNFERMLINE, JAMES ABERCROMBY, 1ST BARON (1776-1858), speaker of the House of Commons, third son of Gen. Sir Ralph Abercromby, was born on Nov. 7, 1776. He was

called to the bar at Lincoln's Inn in 1801. He sat in parliament for Midhurst (1807) and Calne (1812) in the Whig interest. In 1870 Abercromby was made judge advocate general, and chief baron of the exchequer of Scotland in 1830, when he resigned his seat in parliament. He joined the cabinet of Earl Grey in 1834 as master of the mint. In the new parliament of 1835, Abercromby was elected speaker of the house. As speaker he was not very successful in quelling disorder, but he introduced several important reforms in the management of private bills. On his resignation in May 1839 he was created Baron Dunfermline of Dunfermline. He died at Colinton house, Midlothian, on April 17, 1858, and was succeeded in the title by his only son, Ralph. See Spencer Walpole, *History of England* (London, 1890), *Gessell's Memoirs*, edited by H. Reeve (London, 1896), Lord Cockburn's *Journal* (Edinburgh, 1874).

DUNFERMLINE, a royal, large and parliamentary burgh, Fifeshire, Scotland (Gaelic, "the fort on the crooked inn"). Pop. (est. 1938) 37,058. The burgh includes Rosyth, which was added to it in 1911. It is situated on high ground 3 mi. from the shore of the Firth of Forth, with two stations on the N.E.R.—Lower Dunfermline 1½ mi., and Upper Dunfermline 1½ mi. N.W. of Edinburgh, via the Forth Bridge. The town is intersected from north to south by Pittencrieff park, a deep, picturesque ravine, from which the town derives its name and at the bottom of which flows Lyne Burn.

The early Celtic monks known as Culdees had an establishment here, but its fame dates from the marriage of Malcolm Canmore and his queen Margaret, solemnized in the town in 1070. The king then lived in a tower on a mound surrounded on three sides by the glen. A fragment of this castle exists in Pittencrieff park, a little west of the later palace. Under the influence of Queen Margaret in 1075 the foundations were laid of the Benedictine priory, raised to an abbey by David I. Robert Bruce gave the town its charter in 1322.

The staple industry is the manufacture of table linen. The weaving of damask was introduced in 1718 by James Blake, who had learned the secret of the process in the workshops at Drumsheugh near Edinburgh. Other industries are dyeing and bleaching, silk manufacturing, brass and iron founding, engineering works, ropemaking and the making of soap and fireclay, while there are numerous collieries in the immediate vicinity.

Public edifices, besides churches, include the county buildings, the Public, St. Margaret's, Music and Carnegie halls, the last in the Tudor style, Carnegie public baths, high school (founded in 1560), school of science and art and two hospitals. Andrew Carnegie (1835-1919) was a well known benefactor of Dunfermline. He gave to his birthplace the free library and public baths, and, in 1903, the estate of Pittencrieff park and glen, rich in historical associations as well as natural charm, together with bonds worth £500,000 (increased by £250,000 in 1911) a year, in trust for the maintenance of the park, the support of a theatre for the production of plays of the highest merit, the periodical exhibitions of works of art and science, the promotion of horticulture among the working classes and the encouragement of technical education in the district. A statue of Carnegie was placed in the park, and Dunfermline became the headquarters of all the Carnegie trusts. The town is the seat of the sheriff-substitute for western Fife, it is governed by a provost, bailies and council, and, with Cowdenbeath, Inverkeithing and Lochgelly (the Dunfermline group) combines in returning one member to parliament.

With the exception of Iona, Dunfermline abbey has received more of Scotland's royal dead than any other place in the kingdom. Within its precincts were buried Queen Margaret and Malcolm Canmore, their sons Edgar and Alexander I, with his queen, David I and his two sons, Malcolm IV, Alexander III, with his first wife and their sons David and Alexander, Robert Bruce, with his queen Elizabeth and their daughter Matilda, and Anna-Bella Drummond, wife of Robert III and mother of James I. Bruce's heart rests in Melrose, but his bones lie in Dunfermline abbey, where (after the discovery of the skeleton in 1818) they were reinterred below the pulpit of the New church. In 1891 the pulpit was moved back and a monumental brass inserted in the

floor to indicate the royal vault. The tomb of St. Margaret and Malcolm, within the ruined wall of the Lady chapel was restored and enclosed by command of Queen Victoria. During the winter of 1303 the court of Edward I was held in the abbey, and on his departure next year most of the buildings were burned. When the Reformers attacked the abbey church in March 1560 they spared the nave, which served as the parish church till the 19th century and now forms the vestibule of the New church (1821), a building in the Perpendicular style. The old building was a fine example of simple and massive Norman and has a beautiful doorway in its west front. Another rich Norman doorway was exposed in the south wall in 1903. On the south side of the churchyard are the early 14th century ruins of the priory and dormer connected by a gatehouse with the remains of the kitchen and guest house, which was later the palace. The palace, a favourite residence of many of the kings, occupying a picturesque position near the river, was of considerable size, judging from the southwest wall which is all that is left of it, the last royal tenant was Charles II, who occupied it just before the battle of Pittencrieff (July 20, 1650), which took place 3 mi. to the southwest and there also signed the National League and Covenant.

DUNGANNON, a market town and urban district of Co. Tyrone, Northern Ireland, 8 mi. W. of the SW. shore of Lough Neagh, 32 mi. from Belfast by the G.N. railway, with a branch line thence to Cookstown. Pop. (1937) 3,920. Area, 4 sq. mi. Its early history is that of the O'Neills, whose chief residence was there, and a large rath or earthwork north of the town was the scene of the inauguration of their chiefs, but of the family castle and abbey there are no remains. In Dungannon the independence of the Irish parliament (to which the town returned two members) was proclaimed in 1782. The town was formerly corporate and was a parliamentary borough until 1885. The royal school, founded in 1614, was moved to new buildings at the end of the 18th century. The pork market is important, and soap and candle making are the main industries.

DUNGARPUR, an Indian state, in the Rajputana agency in the extreme south of Rajputana. A large portion is hilly, and inhabited by Bhils. Its area is 1,460 sq. mi. In 1941 the total population was 274,382. Kherwara is the headquarters of the Mewar Bhil corps.

The chiefs of Dungarpur, who bear the title of maharawal and enjoy a salute of 15 guns, are descended from Mahup, eldest son of Karan Singh, chief of Mewar in the 12th century, and claim the honours of the elder line of Mewar. The town of Dungarpur (pop. 8,670 in 1941), the capital of the state, was founded towards the end of the 14th century and named after Dungaria, an independent Bhil chieftain. After the battle of Khanua in 1527, these territories were divided into the states of Dungarpur and Banswara. Dungarpur fell under the sway of the Moguls and Marhattas in turn and was taken under British protection by treaty in 1818.

DUNGARVAN, a market town and seaport of Co. Waterford, Eire, 2½ mi. WSW. from Waterford by rail. Pop. of urban district (1936) 5,361. It is situated on the Bay of Dungarvan, at the mouth of the Coligan, which divides the town into two parts. Dungarvan was incorporated in the 15th century. Under John, walls were built, also a castle, of which there are still remains in the town. The eastern suburb is called Abbeyside, where remains of an ancient keep, erected by the McGraths, still exist, together with portions of an Augustinian friary, founded by the same family in the 14th century and incorporated with a Roman Catholic chapel. Brewing is carried on and there are woollen mills. Trade is in agricultural produce.

DUNGENSESS, promontory, south coast of Kent, England, near the town of Lydd. It is a low-lying bank of about 0.4 sq. mi. of shingle, forming the seaward apex of the great Romney marshes. Its seaward accretion by the formation of curved shingle beaches is about 6 ft. annually. The sea quickly dries up to deep water, which is not the case of the other headlands of the south coast. A lighthouse (50° 55' N., 0° 58' E.) stands on the ness. There are also here Lloyds' signalling station, a bird sanctuary and the terminus of a branch of the Southern railway.

The name Dungeness has also been applied elsewhere, thus the point on the north side of the eastern entrance to Magellan strait is so called, and there is a town of Dungeness near a promontory on the coast of Washington, U.S.A. (Strait of Juan de Fuca).

DUNGEON, the prison in a castle. The word is an anglicization of *dungeon*, the French for keep (*q.v.*), in whose cellars the prison is usually located. In modern usage, *dungeon* signifies, specially, the vaulted chambers that formed these prisons, hence any small, vaulted, prison-like room, particularly if dark or artificially underground.

DUNKELD AND DOWALLY, a civil parish of Perthshire, Scotland, on the left bank of the Tay, 15½ mi N.W. of Perth by the L.M.S.R. The station is at Birmam, on the right bank. Pop. (1931) 946. The river is crossed by a bridge of seven arches designed by Thomas Telford and opened in 1808.

As early as 129—some authorities fix the date a hundred and fifty years before—the Culdees possessed a monastery at Dunkeld, converted into a cathedral by David I in 1127. At the Reformation it was unroofed and fell into ruin. The building, given to the nation by the duke of Atholl in 1918, consists of the nave, aisles, choir, chapter house and tower. The pointed arches rest upon pillars, possibly Norman, and above them, below the Decorated clerestory windows, is a series of semicircular arches with flamboyant tracery. The choir, founded by Bishop William Sinclair (d. 1337), has been repaired, and serves as the parish church, a blue marble slab in the floor marking the bishop's grave. The chapter house, adjoining the choir, was built by Bishop Thomas Lauder (1395–1481) in 1469, and the vault beneath is the burial place of the Atholl Murrys. Lauder also began the tower, completed in 1501. The most famous of the bishops was Gavin Douglas (1474–1522), translator of the *Aeneid*. Shortly after the battle of Killcrankie (1689), the Cameronian regiment which was enrolled in the same year (afterwards the 26th Foot), was despatched to hold Dunkeld prior to another invasion of the Highlands. It was under the command of Colonel William Cleland (1667–89), a poet of some merit. On Aug. 26 a force of 5,000 Highlanders suddenly appearing, Cleland posted his men in the church and behind the wall of the east of Atholl's mansion. The Highlanders were forced to withdraw, but while leading a sortie Cleland was killed.

Adjoining the cathedral is Dunkeld house, a seat of the duke of Atholl. The 4th duke planted several square miles of the estate with larches. The oak and sycamore in front of Birmam house, 1 mi S., are believed to be the remnant of the wood of Birmam which Shakespeare immortalized in *Macbeth*. The Press of Birmam, where the river furrows, is the path usually taken by the Highlanders in their loaves. In the vicinity are the castles of Muthil, one an old one, still occupied which was occasionally used as a hunting lodge by the Scottish kings. Birmam and Muthil are in the civil parish of Little Dunkeld.

DUNKIRK, a seaport of northern France (Fr. *Dunkerque*), capital of a *departement* in the *departement* of Nord, on the Straits of Dover, 53 mi N.W. of Lille on the Northern railway. Pop. (1946) 105,775. Around a chapel founded by St. Eloi in the 7th century a small village sprang up, and, in the 16th century, was fortified by Baldwin III, count of Flanders. In 1658, after the victory of the Dunes (1658) given into the hands of the French and it was ceded to Cromwell in return for services of the Ironsides. Charles II sold it to Louis XIV, who fortified it. By the terms of the peace of Utrecht (1713) the fortifications were demolished and its harbour filled up, a sacrifice demanded by England owing to damage inflicted by Jean Bart and other corsairs of the port. In 1793 it was besieged by the English under Frederick Augustus, duke of York, who was compelled to retire after the defeat of Hondschoote. It was heavily bombed and damaged in World War I, during which it was for most of the time, 18 mi behind the Allied front, and in World War II Dunkirk is in the low but fertile district of the Waterings. It lies, amid a network of canals, immediately to the west and south of its port, which disputes with Bordeaux the rank of third in importance in France. The populous suburbs of Rosendael and St. Pol-sur-Mer lie respectively to the east and west of the town, to the north-east is the bathing resort of Malo-les-Bains. The streets of Dunkirk

are wide and well paved, the chief of them converging to the square named after Jean Bart (born at Dunkirk in 1651), whose statue by David d'Angers stands at its centre. Close to the Place Jean Bart rises the 16th century belfry (290 ft. high) which contains a fine peal of bells and also serves as a signalling tower. It was once the western tower of the church of St. Eloi, from which it is now separated by a street. St. Eloi, erected about 1560 in the Gothic style, was deprived of its first two bays in the 18th century, the present facade dates from 1889. The roof was destroyed in World War I. The chapel of Notre Dame des Dunes possesses a small image, which is the object of a well known pilgrimage. The large chamber of commerce includes the customs and port services. Dunkirk is the seat of a sub-prefect, its public institutions include tribunals of first instance and of commerce, a board of trade arbitrators, an exchange, a branch of the Bank of France and a communal college, and it has a school of drawing, architecture and music, a library and a rich museum of paintings. Dunkirk forms with Bergues, Bourbourg and Gravelines a group of fortresses enclosed by inundations and canals.

The harbour of Dunkirk (see DOCKS) is approached by a fine natural roadstead entered on the east and west, and protected on the north by sandbanks. From the roadstead, entrance is by a channel into the outer harbour, which communicates with seven floating basins about 1½ acres in area and is accessible to the largest vessels.

The port is provided with four dry docks and a griddon, and its quays exceed 5 mi in length. Canals bring it into communication with Belgium, the coal basins and industrial towns of Nord and Pas de Calais, and the rich agricultural regions of Flanders and Artois. The roadstead is indicated by lightships and the entrance channel to the port by a lighthouse which, at an altitude of 193 ft., is visible at a distance of 19 mi.

Dunkirk annually dispatches a fleet to the Icelandic cod-fisheries, and takes part in the herring and other fisheries. It imports great quantities of wool from the Argentine and Australia, and is in regular communication with New York, London and the chief ports of the United Kingdom, Brazil and the far East. Besides wool, leading imports are jute, cotton, tow, flax, timber, petroleum, coal, iron ore, pig iron, pitch, wine, cereals, oilseeds and oil cake, nitrate of soda and other chemical products, and metals.

The principal exports are sugar, coal, cereals, wool, forage, cement, chalk, phosphates, iron and steel, tools and metal goods, thread and vegetables.

Dunkirk is the third port of France. The industries include the spinning of jute, flax, hemp and cotton, iron founding, and the manufacture of machinery, fishing nets, sailcloth, sacks, casks and soap. There are also saw- and flour mills, petroleum refineries and oil works. Shipbuilding is carried on and the preparation of fish and cod-liver oil occupies many hands.

For the evacuation of Dunkirk see WORLD WAR II.

DUNKIRK, a city of Chautauqua county, New York, on Lake Erie, 40 mi S.W. of Buffalo. It is a port of entry and is served by the Erie, the New York Central, the Pennsylvania, the Nickel Plate and the Dunkirk, Allegheny Valley railways. The pop. (1950) was 17,965. It is a shipping point for quantities of agricultural products, particularly Concord grapes, and has import and manufactures including tool steel and stainless steel wire, petroleum products, chemicals, utility and marine equipment, shovels, hoes, glass, wire, radiators and boilers, valves, automotive parts, gloves and lingerie.

Dunkirk was settled about 1805, incorporated as a village in 1837, with 700 inhabitants, and chartered as a city in 1880. It owes its name to the similarity of its harbour to that of Dunkirk, France.

DUNLIN or OLBIRD (*Erolia alpina*), one of the commonest of the sandpipers (*q.v.*). It breeds on elevated moors in Europe, N. Asia and N. America and in winter haunts the mud flats and sand banks in large flocks. A smaller race *E. a. schinzii* occurs in Britain and Baltic Europe. In the breeding season, the male utters a peculiar whistle.

A subspecies of the dunlin, the red-backed sandpiper (*Erolia*

alpina sakhalina), is abundant on both the Atlantic and Pacific coasts of North America.

DUNLOP, JOHN BOYD (1840-1921), Scottish inventor, the pioneer of the pneumatic rubber tire, was born on Feb. 5, 1840, on a farm at Dreghorn, Ayrshire. He settled in 1867 as a veterinary surgeon in Belfast, where he had a large and successful practice. In 1887 he constructed a pneumatic tire for his little boy's tricycle. The invention was tested, and patented on Dec. 7, 1888. Two years later production on a commercial scale began, in conjunction with William Harvey Du Cros by the Pneumatic Tyre and Booth Cycle agency, Belfast. Dunlop made over the patent to Du Cros for a moderate sum, and took 1,500 shares in the company. Some difficulty arose when it was discovered that the principle of the pneumatic tire had been patented in 1846 by an inventor named Thompson, but the company held various accessory patents which enabled them to establish their position. Dunlop himself did not make a great fortune by the invention, as he took no further part in the great developments which followed the sale of the company in 1896 to E. T. Hooley, who refloated it for £5,000,000.

Dunlop died in Dublin, where he had an interest in a drapery firm, on Oct. 23, 1921. See Jean McClintock (his daughter), *History of the Pneumatic Tyre* (1923).

DUNLOP, JOHN COLIN (1785-1842), Scottish man of letters, was born on Dec. 30, 1785. In 1816 he became sheriff of Renfrewshire, and retained this office until his death at Edinburgh in 1842. His *History of Fiction* (1814, new edition, 1838, with notes by H. Wilson, in Bohn's "Standard Library") is a standard work on the subject. Dunlop was also the author of *A History of Roman Literature* (1823-28), and of *Memoirs of Spain during the Reigns of Philip IV and Charles II* (1834).

DUNLOP RUBBER COMPANY, LTD. In 1888 J. B. Dunlop invented a pneumatic tire which was really a re-invention, the first pneumatic tire having been patented in 1846. A company was registered in Ireland in 1889 to exploit Dunlop's invention with £15,010 issued capital. Prior to Dunlop's invention cycle tires were made of solid rubber. The first pneumatics were received with demerit but quickly established their superiority, cycles were made lighter and propulsion was infinitely easier. The motor car began to use them. In 1896 the Dunlop Pneumatic Tyre Co. was formed with £5,000,000 capital.

Up to 1899 the Tyre Co. had no rubber mills, but it then acquired a rubber manufacturing company in Birmingham which had a capital of £20,000. The name of the company so acquired was changed to Dunlop Rubber Co., and in 1912 it acquired all the trading rights of the Tyre Co., thus amalgamating the manufacturing and selling in one company. The share and loan capital held by the public in the Dunlop Rubber Co. and its English subsidiaries amounted in 1939 to over £20,000,000. In addition to tires, the company manufactures wheels and rims for motor vehicles of all kinds, aeroplanes and cycles, footwear, clothing, general rubber goods of every description, tennis rackets, tennis and golf balls, and various other sports requisites. In addition to 11 factories in England it owns through subsidiary companies the largest cotton mills in the world (at Rochdale) and rubber estates in Malaya with over 85,024 acres planted. There are Dunlop factories in America, France, Germany, Australia, Canada, India, South Africa, Eire, and Japan.

(A. T. F.)
DUNMORE, JOHN MURRAY, EARL OF (1732-1809), English governor of Virginia, succeeded to the peerage in 1756. He sat in the House of Lords from 1761 until he became governor of the colony of New York in 1770. In 1771 he was also appointed governor of Virginia. He made himself unpopular by dissolving the assembly in 1772, 1773 and 1774 because of its expression of revolutionary sentiments. Early in 1775 he removed the powder from the magazine at Williamsburg, Va., and thus occasioned the first armed uprising of Virginia. This led him to remove the seat of government to a man-of-war lying off Yorktown. Further disagreements led the burgesses to contend that he had abdicated. Dunmore returned to England in 1776, and in 1787 was made governor of the Bahamas, a post which he held until 1796. Later critics have felt that the Indian War (see **POINTE**

PLEASANT) which bears his name was prompted largely by his greed for western land. He died at Ramsgate in May 1809.

See C. W. Alvord, *The Mississippi Valley in British Politics* (1917), and *Documentary History of Dunmore's War*, edited by F. G. Thwaites and L. P. Kellogg (Madison, Wis., 1905).

DUNMORE, a borough of Lackawanna county, Pa., U.S., adjoining Scranton on the northeast. It is served by the Erie, the Lackawanna, and the Lackawanna and Wyoming Valley (electric) railways. Pop. (1950) 20,302, (1940) 23,086 by the federal census. Anthracite mining and work on the railroads are the principal occupations. There are also car shops, silk mills and shoe and fabric glove factories. The Pennsylvania State Oral School for the Deaf is located between there and Scranton. Dunmore was settled in 1783 and incorporated as a borough in 1862.

DUNMOW or **GREAT DUNMOW**, a market town of Essex, England, on the river Chelmer, 40 mi. NNE from London on a branch from Bishop's Stortford of the LNE railway. Pop. of civil parish (1931) 2,882. The church of St. Mary is Decorated and Perpendicular. The town was corporate from 1556 until 1886. Roman remains have been discovered. The manufacture of baize was introduced there in the 17th century but became extinct. Two miles east is the village of **LITTLE DUNMOW**. The old church of St. Mary, Little Dunmow, contains some interesting early monuments. Here was burned Robert Fitzwalter, "Marshal of the Army of God and Holy Church," who was leader of the barons who negotiated Magna Carta. It was formerly the seat of an Augustinian priory, remarkable for the custom of presenting a fitch of bacon to any couple who could give proof that they had spent the first year of married life in unbroken harmony. Later in place of the monastic judicature, a jury of six bachelors and six maidens appears in the 16th century. A rhyming oath, quoted by Fuller, was taken. This institution, which had its parallel at Whitchance (or Wichnor) in Staffordshire, at St. Moline in Brittany, and apparently also at Vienna, appears to be of very ancient origin. The first recorded instance of its award is in the reign of Henry VI. But there are references which point to it in *Piers Plowman* and Chaucer. The manorial documents relating to it are kept in the church. The custom was revived in 1855 by Harrison Answorth, author of the novel *The Fitch of Bacon*, but the scene of the ceremony was transferred to the old town hall of Great Dunmow. (For details see Chambers' *Book of Days*, ii, 748-751, and W. Andrews, *History of the Dunmow Fitch of Bacon Customs*, 1877.)

DUNNE, FINLEY PETER (1867-1936), American journalist and humorist of Irish descent, was born in Chicago, Illinois, July 10, 1867, and educated in the public schools. In 1885 he became a newspaper reporter. Later he was a member of the editorial staff of the *Chicago Evening Post*, and of the *Chicago Times-Herald* (1892-97), and editor of the *Chicago Journal* (1897-1900).

For several years he contributed humorous sketches in Irish brogue to the daily papers, but he did not come into prominence until he wrote for the *Chicago Journal* a series of satirical observations and reflections on social and political topics of the day, attributed to an honest Irish-American, Martin Dooley, the shrewd philosopher of Archey road. They were widely copied by the press of America and England.

The first published collection, *Mr. Dooley in Peace and in War* (1898), was followed by several others, similar in subject matter and in method, including *Mr. Dooley's Philosophy* (1900), *Observations by Mr. Dooley* (1902), and *Mr. Dooley Says* (1910). These books made their author famous as the creator of a delightfully original character and as a humorist of shrewd insight.

DUNNOCK, a name for the European hedge sparrow (*Pinella modularis*). (See **HEDGE SPARROW**.)

DUNOIS, JEAN, COMTE OF (1403-1468), commonly called the "Bastard of Orleans," a celebrated French commander, was the natural son of the duke of Orleans (brother of Charles VI.) and Mariette d'Enghien, Madame de Cansy. His earliest feat of arms was the surprise and rout in 1427 of the English, who were besieging Montargis—the first successful blow against the English power in France following a long series of French defeats. In 1428 he

defended Orleans with the greatest spirit, and enabled the place to hold out until the arrival of Joan of Arc, when he shared with her the honour of defeating the enemy there in 1429. He then accompanied Joan to Reims and shared in the victory of Patay. After her death he raised the siege of Chartres and of Lagny (1432) and engaged in a series of successful campaigns which ended in his triumphal entry into Paris (April 13, 1436). He gradually drove the English northward, in 1450 he reconquered northern France, and in 1451 attacked the English in Guenne, taking among other towns Bordeaux and Bayonne. In 1465 he joined the league of revolted princes, but, assuming the function of negotiator, he was after a time reinstated in his offices. He died on Nov. 24, 1468.

DUNOON, a small burgh of Argyllshire, Scotland on the west shore of the Firth of Clyde, opposite to Gourock. Pop. (est. 1938) 7,902. Area, 1,6 sq. mi. (These figures are usually increased in the holiday season.) Including Kilm and Hunter's Quay, it presents a practically continuous front of seaside villas, with an esplanade two miles long. The mildness of its climate and the beauty of its situation have made it one of the most prosperous watering-places on the west coast. On a conical hill above the pier stand the remains of Dunoon Castle, the hereditary keepership of which was conferred by Robert Bruce on the family of Sir John Campbell of Loch Awe, an ancestor of the duke of Argyll. It was visited by Queen Mary in 1563, and in 1643 was the scene of the massacre of the Lamonts by the Campbells. The grounds have been laid out as a recreation garden. The town itself is modern, having been a mere fishing village at the beginning of the 19th century. There is frequent communication by steamer with Greenock. Hunter's Quay is the yachting headquarters, the Royal Clyde Yacht Club's house adjoining the pier. Kilmun, on the northern shore of Holy Loch, a portion of the civil parish of Dunoon and Kilmun (pop. 1931, 12,361), contains the ruins of a Collegiate chapel founded in 1447 by Sir Duncan Campbell of Loch Awe and used as the burial ground of the Argyll family.

DUNS, a small burgh and the county town of Berwickshire. Scotland. Pop. (est. 1938) 1,874. It is situated 44 mi. ESE of Edinburgh by road, with a station on the branch line of the LNER from Reston to St. Boswells. Trade in grain and flour is carried on, and stock sales are held. On Duns Law (700 ft.) the Covenanters, under Alexander Leslie, were encamped in 1639, and the Covenanters' Stone on the top of the hill has been enclosed. Duns castle, adjoining the town on the W, includes the tower erected by Thomas Randolph, earl of Moray (d. 1332).

DUNSANY, EDWARD JOHN MORETON DRAX PLUNKETT, 18TH BARON (1878-), Irish dramatist, was born in London on July 24, 1878. He was educated at Eton and Sandhurst, and succeeded his father as 18th Baron Dunsany in 1899. Entering the Coldstream Guards, he served in the Boer War and, in the Royal Inniskilling Fusiliers, in World War I. As a playwright, he first attracted attention with *The Glistening Gate*, produced in Dublin, 1909. His plays are expressed in richly coloured language. They include *The Gods of the Mountain* (1911), *A Night at an Inn* (1916), *If* (1921), *Alexander and Other Plays* (1925), and *Plays for Earth and Air* (1937). Fictional tales in a similar style include *The Gods of Pegana* (1905), *The Sword of Welleran* (1908), *Tales of Wonder* (1916), *Old King's Tale* (1926), and *The Story of Mona Sheehy* (1940). His autobiography, *Patches of Twilight*, appeared in 1938.

DUNSLANE, a peak of the Sidlaw hills, in the parish of Collace, Perthshire, Scotland, 8 m. north east of Perth. It is 1,012 ft. high, and commands a fine view of the Carse of Gowrie and the valley of the Tay. Its chief claim to mention, however, is due to its association with Birnam Wood (about 12 m. NW) in two well known passages in Shakespeare's *Macbeth*. An old fort on the summit, of which faint traces are still discernible, is traditionally called Macbeth's castle.

DUNS SCOTUS, JOHN (c. 1265-1308), the famous doctor subtilis and the greatest British mediaeval philosopher, was born in the village of Duns, Scotland. He became a Franciscan and studied at Oxford where shortly after 1290 he lectured on the *Sentences*. He then spent some four years in Paris, and after returning to Oxford, was again, by 1302, lecturer in Paris. There

he received the master's licence. He was transferred to Cologne, where he died on Nov. 8, 1308.

Broadly speaking, Scotus, like Bonaventure and Pecham, seeks to defend the traditional Scholastic doctrines against Thomistic innovations (the same desire had already led Bishop Tempier of Paris to condemn in 1277 a number of Thomistic theses), and in so doing, incidentally manifests the scientific bent of the Oxford Franciscan school by his hesitation in accepting what others regard as proof. He is commonly represented only as a destructive critic of St. Thomas, which is to say, as a Franciscan antagonist to a Dominican, but, in reality, the critical position involved in many of his famous speculations, e.g., his doctrine of the Trinity, his formal distinction in God, the univocity of being in God and creatures, and the importance of the *species intelligibiles*, applies to the system of Henry of Ghent, while his voluntaristic leanings are a protest against Godfrey of Fontaine's stress on the passivity of the will. His is the legitimate aim of contributing to philosophical speculation by evaluating the theories of others. Again, certain superficial readers have absurdly accused Scotus, whom Thomas Cromwell in the 16th century attacked as the great defender of Scholasticism, of pantheism, scepticism, Pelagianism, indeterminism, excessive realism, subjectivism and a host of other imaginable iniquities. These accusations are due either to the assumption of the genuineness of the *De Rerum Principio*, now rejected by all first rate scholars, or to a lack of patience in coping with the subtle and extensive writings of Scotus.

Bearing in mind the common doctrines of the Schoolmen (see SCHOLASTICISM), the chief points of interest in the metaphysics of Scotus are his rejection of the Augustinian theory of *rationes seminales* in matter, a theory which he regards as uselessly multiplying entities and as destroying the true nature of becoming, his contention that matter is not pure passive potency but has some positive entity of its own and, therefore, by the absolute power of God, could exist apart from form, his denial of the numerical unity of matter in all things, his belief that the form is educed successively from the potency of matter, that the resulting composite has in itself both a universal and an individual nature, the latter, which for Scotus means repugnance to division into subjective parts, being due to none of the factors usually suggested, e.g., negation, existence, accidents, matter and quantity, but to a positive entity (*haecceitas*), an *ultima realitas entis*, which is a unity of this matter with this form in this composite.

In cosmology his two most important doctrines are those which maintain that elements must remain at least virtually in compounds, since they can be regained from them, and that the Ptolemaic system of eccentric and epicycles is necessary to account for the phenomena observable in the movements of the celestial bodies.

In psychology, Scotus naturally upholds the theory of the plurality of forms in man, since he is interested in proclaiming the separability and independence of the rational soul and the body. The soul is created by God and is immortal, though its immortality for Scotus, contrary to the general Scholastic opinion, cannot be positively proved but only supported by possible persuasions. As regards the hylomorphic composition of the soul, a doctrine which had been proclaimed by all his Franciscan predecessors, Scotus neither accepts nor rejects it in his genuine works. The faculties of intellect, will and memory through which the soul acts, are for him, neither really distinct from the soul's essence, for that would imply their separability, nor only logically distinct, for then they would exist *potentially* rather than *actually*, they are formally distinct, which is to say, they are inseparably founded in the essence *ex natura rei* and yet cannot be included in the same definition.

His view of cognition is very much the common Scholastic doctrine of moderate realism, except that he stresses the activity of the intellect, including the passive as well as the active intellect, and the importance of induction, that he rejects the Augustinian doctrine of Divine illumination, and that he maintains we have a direct though imperfect intuitive knowledge of singulars. In discussing our knowledge of spiritual beings, he denies that we have

an immediate knowledge of the self and that we can have any other than a *posteriori* proofs for the existence of God. His assertion that the concept of being which we apply to God is univocal with that applied to creatures, is meant to avoid agnosticism by proclaiming that our concept gives us some positive knowledge of the quiddity of being in God. He does not countenance pantheism by supposing that the actual realization of being in God is univocal with created being. All activities of the human intellect are closely related to those of the will, and hence, attention is a *sine qua non* for knowledge, just as much as a known object is essential for an act of will. Nevertheless, if the will requires such direction, it is not determined by the intellect. It is still able to deliberate and it alone must accept or reject. It is just this emphasis on the will which has led to Scotus being called an extreme voluntarist, but, in reality, the necessity of interaction between intellect and will is fully recognized by the subtle doctor, the primacy of the will being more pronounced only in the supernatural life.

In angelology, the chief contributions of Scotus are his decision as to their hylomorphic composition, his denial that each angel is a complete species, his opinion that, if the angelic beings are capable of development, they must receive *species intelligibiles* from externals and must also possess a passive as well as an active intellect, and his assertion that the angelic will has a dependency of activity as regards the intellect but a primacy of nature.

Finally in theodicy, the most important contributions of Scotus are his formal distinction between the Divine attributes, and the Divine essence, which means that the attributes can be more than conceptual without impeding the Divine simplicity, his rejection of Henry of Ghent's *esse essentiae simpliciter* for the existence of things in the mind of God before creation, his support of the Divine knowledge of singulars and of the necessity of interaction between the Divine intellect and will, the latter being limited only according to the distinction between God's absolute power and his ordained power, and lastly his discussion of the unsatisfactory objections both to the theory of the possibility of eternal creation and to that of the necessity of a temporal creation. The teaching of Scotus on the relation between reason and faith is practically that of St Thomas.

BIBLIOGRAPHY—The uncritical edition of the works of Scotus by Wadding, 13 vols. (Lyons, 1639) was reprinted at Paris, 26 vols. (1897-98). Of these, as E. Longpré, *La Philosophie du B. Duns Scot* (Paris, 1924), has shown, only the *Opus Oxon.*, the *Rep. Paris. Quod De Primo Principio* and the *Questiones on the Metaphysics* can be unquestionably accepted as genuine.

As regards the life of Scotus, all that can be said with certainty has been summarized by A. G. Little, "The Franciscan School at Oxford" in *Arch. Fran. Hist.* (1926, p. 869 sq.). The most trustworthy accounts of the philosophy of Scotus are to be found in Longpré (see above), J. Klein, *Der Gottesbegriff des D. Scotus* (Paderborn, 1913), H. Kilgus, "Die Lehre des Scotus über Materie und Form" in *Philos. Jahrb.* (1917), P. Minges *Ist Duns Scotus Indeterminist* (Münster, 1905) and *Der angeblich exzessive Realismus des Duns Scotus* (Münster, 1908), R. Seeberg, *Die Theologie des Duns Scotus* (1900), K. Werner, *Die Psych. u. Erkenntnistheorie des Scotus* (Vienna, 1877) and *Die Scholastik des späteren Mittelalters*, vol. 1 (Vienna, 1881). B. Landry, *Duns Scot* (Paris, 1932) is most uncritical, and C. R. S. Harris, *Duns Scotus*, 2 vols. (Oxford, 1927) is largely based on the spurious *De Rerum Principio*.

DUNSTABLE.

Watling street, while the high road from Luton to Linn, which crosses it in the centre of the town, represents the ancient Ickneld way. The straw hat industry which formerly flourished here moved to Luton, but there is an extensive printing works, and brewing, foundry and chain works, besides a manufactory of spark plugs. The borough is under a mayor, 6 aldermen and 12 council loids, and has a separate commission of the peace.

It appears probable that there was a Romano British village on this site corresponding to the *Forum Dunaee* of the Romans. Many interesting fragments have been found, also a walled camp of c. A.D. 9, called "Madden Bower." Dunstable (*Dunstaple*) appears as a royal borough in the reign of Henry I who in 1131 founded and endowed a priory with the lordship of the manor and borough, which it retained till its dissolution in 1536-37. The *Dunstable Annals* deal exhaustively with the history of the monastery and town in the 13th century. At Dunstable Ciammer held the court which, in 1533, declared Catherine of Aragon's marriage invalid.

Dunstable has always been an agricultural town. The *Annals* abound with references to the prices and comparative abundance or scarcity of the two staple products, wool and corn. In 1834 the town was made a municipal borough. It was extended in 1893. Whipsnade, the country branch of the London zoo, was opened in 1931, occupying 500 ac. 34 mi. by road from Dunstable.

DUNSTAN, SAINT (909-988), English archbishop and son of a West Saxon noble, was born near Glastonbury, where he was educated by the Irish pilgrims. He entered the household of King Aethelstan, but his love of books and of song and his mechanical skill soon excited the dislike of his kinsfolk at the court. Accused of practising the black arts, he took refuge with his kinsman, Alphege, bishop of Winchester, whose persuasion seconded by a serious illness, induced him to become a monk. Dunstan then lived as a hermit near the old church of St. Mary until Aethelstan's successor, Edmund, recalled him as one of his counsellors. His enemies again procured his expulsion, but Edmund soon revoked the sentence, and about 943 made Dunstan abbot of Glastonbury. Under him the abbey became a famous school, monastic life was revived and St. Peter's re-erected. Edred, the successor of Edmund, left the administration of the realm largely in the control of Dunstan, who sought to establish royal authority, to conciliate the Danish section, to uproot heathenism and to reform the secular clergy and the laity. On the accession of Edwg., however, in 955, Dunstan's fortunes underwent a temporary eclipse. Having given offense to the influential and unprincipled Aelfgifu, he was outlawed and driven to Flanders. But in 957 the Mercians and Northumbrians revolted and chose Edgar as their king. The new king at once recalled Dunstan, who was appointed to the see of Worcester as soon as it fell vacant. In 959 he also received the bishopric of London. In the same year Edwig died and Edgar became sole king. Dunstan now became archbishop of Canterbury. On Edgar's death in 975 the archbishop secured the crown for his elder son, Edward, who was murdered three years later. On the accession of Aethelred Dunstan's public career came to an end, he retired to Canterbury, where he died on May 19, 988.

Dunstan was one of the chief English saints until his glory was overshadowed by Thomas a Becket. He sought to reform monasticism according to the strict observance of the Benedictine rule, which he had seen at the abbey of Blandinium, near Ghent during his exile under Edwig, and by the re-building of churches and the promotion of education, he endeavoured to uplift his people. In political matters his policy was, as we have said, one of unification and of respect for law.

See *Memorials of St. Dunstan*, edit. W. Stubbs in the *Rolls Series* (1874), *Anglo-Saxon Chronicle*, edit. C. Plummer (Oxford, 1892-99), the *Boxworth Psalter*, edit. Bishop and Gasquet (1908), Freeman, *The Norman Conquest*, vol. 1 (Oxford, 1870) and J. A. Robinson, *The Times of St. Dunstan* (Oxford, 1923).

DUNSTER, a town in the Bridgwater parliamentary division of Somersetshire, England, 14 mi. from the shore of the Bristol channel, on the Minehead branch of the G.W. railway. Pop. of civil parish (1931) 839. Its streets, sloping sharply, contain many old houses. On an eminence stands the ancient castle with its two massive gateways of the 13th and 15th centuries and other early portions, though it has been restored and modernized as a residence. The church of St. George, with its fine tower, is mainly Perpendicular, but has Norman and Early English portions. Near the church are traces of the Benedictine house to which it was attached. The Yarn market, a picturesque octagonal building with deep sloping roof, in the main street, dates from c.

1600 There were British, Roman and Saxon settlements at Dunster (*Torre Dunestorre, Dunester*), fortified against the pirates of the Irish Northmen The Saxon fort of Alaric was replaced by a Norman castle, dating from the Domesday Survey, built by William de Mohun, first lord of Dunster, who founded the priory of St George Before 1183, Dunster had become a mesne borough, owned by the de Mohuns until the 14th century when it was sold to the Luttrells, the present owners Reginald de Mohun granted the first charter between 1245 and 1247 John de Mohun granted other charters in 1301 and 1307 Dunster was represented in parliament in conjunction with Minehead, one of its tithings being part of that borough Representation began in 1562, and was lost in 1832 During this time the port had a considerable wool, corn and cattle trade with Ireland In the middle ages the Friday market and fair in Whit week, granted by the first charter, were centres for the sale of yarn and cloth called "Dunsters," made in the town With the silting up of the harbour, its importance as a port disappeared An 18th century tower on Conegar hill forms a well-known landmark

See Sir H C Maxwell Lyte, *Dunster and its Lords* (1882), *Victoria County History, Somerset*, vol 11

DUNTOCHER (Gaelic, "The Fort of Old hhp"), a small town on Dalmar Burn, in the civil parish of Old Kilpatrick, Dumbar tonshire, Scotland, 9 mi from Glasgow Pop (1931) 2,473 The district contains coal, limestone and ironstone but there is not much mining There are considerable Roman remains there Antoninus' Wall passed immediately to the south, the burn is crossed by a bridge doubtfully alleged to be of Roman origin (restored 1772), subterranean remains indicate a Roman structure, a Roman camp has been traced, and the vicinity has yielded a number of finds, placed in the custody of Glasgow university

DUNTZER, JOHANN HEINRICH JOSEPH (1813-1901), German philologist and historian of literature, was born at Cologne on July 12, 1813 Educated at Bonn and Berlin he settled in 1837 at Bonn as Privatdozent for classical literature He had already, in his *Goethes Faust in seiner Einheit und Ganzheit* (1836) and *Goethes als Dramatiker* (1837), advocated a new critical method in interpreting the German classics, which he wished to see treated like the ancient classics In 1846 he became librarian at the Roman Catholic gymnasium in Cologne, where he died on Dec 16, 1901

Of his works on the German classical poets, especially on Goethe, Schiller and Herder, may be mentioned *Aus Herders Nachlass* (3 vols, 1856-57), *Schiller und Goethe, Übersicht und Erläuterung zum Briefwechsel zwischen Schiller und Goethe* (1859), *Goethes Leben* (1880, 2nd ed 1883, Eng trans 1884), *Schillers Leben* (1881), *Abhandlungen zu Goethes Leben und Werken* (2 vols 1885)

DUNWICH, a village in the Lye parliamentary division of East Suffolk, England, on the coast, 5 mi SSW of Southwold Pop of civil parish (1931) 174 This was in Anglo-Saxon days the most important commercial centre and part of East Anglia It was probably a Romano-British site Early in the 7th century, when Sigebert became King of East Angles, Dunwich was chosen his capital and became the nursery of Christianity in eastern Britain A bishopric was founded (according to Bede in 630 while the Anglo-Saxon chronicle gives 655), the name of the first bishop being Felix Sigebert's reign was notable for his foundation of a school modelled on those he had seen in France, it was probably at Dunwich that four of the nucleus of what afterwards became the University of Cambridge In the middle of the 11th century Dunwich had already suffered from an evil which later caused its total ruin, namely the moving of the sea upon the coast At the Norman Conquest the maror was granted to Robert Malet In 1173 the sight of its strength caused Robert earl of Leicester to despair of besieging Dunwich The town received a charter from King John In the reign of Edward I it is recorded to have possessed 36 ships and brigs, trading to the North seas, Iceland and elsewhere, with 24 fishing boats, besides having until 11 ships of war The Benedictines, Franciscans and Dominicans all maintained establishments here In 1347 more than 400 houses were washed away In 1570, after a terrible storm, appeal was made to Elizabeth But the old walled port was gradually engulfed and

mroads of the sea still continue, the ruined tower of the old church having gone over the cliff during World War I Many relics have been discovered by excavation, and even from beneath the waves Until 1832 Dunwich returned two members to parliament The corporation was abolished in 1886, and part of the civil parish was transferred to Southwold in 1934 In the same year a bishopric suffragan to St Edmundsbury was constituted, receiving the name Dunwich

DUPANLOUP, FELIX ANTOINE PHILIBERT (1802-1878), French ecclesiastic, was born at St Félix in Savoy on Jan 3, 1802, and educated at the seminaries of St Nicolas de Chardonnay and of St Sulpice, Paris In 1825 he was ordained priest, and was appointed vicar of the Madeleine at Paris, being for a time tutor to the Orleans princes He became the founder of the celebrated academy at St Hyacinthe, and received a letter from Gregory XVI eulogizing his work there, and calling him *apostolus juventutis* He became a canon of Notre Dame in 1845 When made bishop of Orleans in 1849, he pronounced a fervid panegyric on Joan of Arc, which attracted attention in England as well as France Before this he had been sent by Arch bishop Affre to Rome, and had been appointed Roman prelate and protomartyr apostolic He was a distinguished educationalist who fought for the retention of the Latin classics in the schools and instituted the celebrated catechetical method of St Sulpice Among his publications are *De l'éducation* (1850), *De la haute éducation intellectuelle* (3 vols, 1866), *Oeuvres choisies* (1861, 4 vols), *Histoire de Jésus* (1872), a counterblast to Renan's *Vie de Jésus* He died on Oct 11, 1878

See F LAGRANGE, *Life* (Eng tr by Lady Herbert, 1885) and E Faguet, *Mgr Dupanloup* (1914)

DUPERRON, JACQUES DAVY (1556-1618), French cardinal, was born at St Lo, in Normandy, on Nov 15, 1556, the son of a Protestant minister, who settled at Berne, Switzerland, where Jacques Davy received his education Returning to Normandy he abjured Protestantism and took orders On the death of Henry III, after having supported for some time the cardinal de Bourbon, the head of the league against the king, Duperron became a faithful servant of Henry IV, and in 1591 was created by him bishop of Evreux He instructed Henry in the Catholic religion, and in 1594 was sent to Rome, where with Cardinal d'ossat (1536-1604) he obtained Henry's absolution At the conference at Fontainebleau in 1600 he argued with much eloquence and ingenuity against Du Plessis Mornay (1549-1623) In 1604 he was sent to Rome as chargé d'affaires While still at Rome he was made a cardinal, and in 1606 became archbishop of Sens In the states general of 1614 he vigorously upheld the ultramontane doctrines against the Third Estate He died in Paris on Sept 6, 1618

See *Les Diverses Oeuvres de l'illustrissime Cardinal Duperron* (1622), Pierre FÉRET, *Le Cardinal Duperron* (1877)

DUPIN, ANDRÉ MARIE JEAN JACQUES (1783-1865), commonly called Dupin the elder, French advocate, president of the chamber of deputies and of the Legislative assembly, was born at Vazzy, in Nièvre, on Feb 1, 1783 Entering the chamber of deputies in 1815, he joined the Liberal opposition At the election after the second restoration Dupin was not re-elected He defended with great intrepidity the principal political victims of the reaction, among others, in conjunction with Nicolas Berrièrre, Marshal Ney, and in October 1815 published a tractate entitled *Libre Défense des accusés* In 1827 he was again elected a member of the chamber of deputies and in 1830 actively supported the revolution At the end of 1832 he became president of the chamber, which office he held successively for eight years On Louis Philippe's abdication in 1848 Dupin introduced the young count of Paris into the chamber, and proposed him, in vain, as king, with the duchess of Orleans as regent In 1849 he was president of the committee of the Assembly on legislation After the coup d'état of Dec 2, 1851, he retained his office of *procureur-général*, until effect was given to the decrees confiscating the property of the house of Orleans In 1857 he was offered his old office by the emperor, and accepted it, explaining his acceptance by the words "I have always," he said, "belonged to France and

never to parties" He died on Nov. 8, 1865. Among Dupin's works, which are numerous, may be mentioned *Principes Juris Criminels*, 5 vols. (1806), *Mémoires et plaidoyers de 1806 au 1^{er} janvier 1830*, in 20 vols., and *Mémoires ou souvenirs du barreau*, in 4 vols. (1855-57). But his greatest work was his share in the codification of the laws of the empire, of which he had sole charge after the interruption of the work of the commission after 1815.

His brother, **FRANÇOIS PIERRE CHARLES DUPIN** (1784-1873), wrote several geometrical works.

DUPIN, LOUIS ELLIES (1657-1719), French ecclesiastical historian, was born at Paris on June 17, 1657, and educated at the college of Harcourt and the Sorbonne, receiving his B.D. (1680) and D.D. (1684). The first volume of his *Notwendige bibliothek des auteurs ecclesiastiques* appeared in 1686, but the liberty with which he treated the doctrines of the Fathers aroused the prejudice of ecclesiastics, including Jacques Bossuet, and, although he consented to a retraction, the book was suppressed in 1696. After passage of the bull *Unigenitus* he was exiled to Châteleraut as a Jansenist, but the sentence of banishment was repealed on a new retraction. His correspondence with William Wake, archbishop of Canterbury, with a view to a union of the English and Gallican Churches, threw further suspicion upon him. The same zeal for union induced him, during the residence of Peter the Great in France, and at that monarch's request, to draw up a plan for uniting the Greek and Roman Churches. He died at Paris on June 6, 1719. Besides his great work, Dupin wrote a *Bibliothèque universelle des historiens*, 2 vol. (1707), *L'Histoire de l'Église en abrégé* (1712), and *L'Histoire profane depuis son commencement jusqu'à présent*, 6 vol. (1714-16).

DUPLEIX, JOSEPH FRANÇOIS (1697-1763), governor general of the French establishment in India, the great rival of Robert Clive (q.v.), was born at Landrecies, Fr., on Jan. 1, 1697. His father, François Duplex, a wealthy farmer general, sent him on a voyage to India in 1715 on one of the French East India company's vessels. He made several voyages to America and India, and in 1721 was named a member of the superior council at Pondicherry. There, besides his official duties, he made large ventures on his own account and acquired a fortune. In 1731 he was made superintendent of French affairs in Chandernagore, which he administered with great success, and in 1742 he was appointed governor-general of all French establishments in India. He determined to acquire for France vast territories in India. The British took the alarm, but the danger to their settlements and power was partly averted by the bitter mutual jealousy between Duplex and La Bourdonnais, French governor of the Isle of Bourbon. When Madras capitulated to the French in 1746 Duplex opposed the restoration of the town to the British thus violating the treaty signed by La Bourdonnais. He then sent an expedition against Fort St. David (1747), which was defeated on its march by the nawab of Arcot, the ally of the British. Duplex succeeded in gaining over the nawab and again attempted the capture of Fort St. David, but unsuccessfully. A midnight attack on Cuddalore was repulsed with great loss. In 1748 Pondicherry was besieged by the British, but in the course of the operations news arrived of the peace of Aix-la-Chapelle. Duplex next entered into negotiations which had for their object the subjugation of southern India, and he sent a large body of troops to the aid of two claimants of the sovereignty of the Carnatic and the Deccan. The British were engaged on the side of their rivals. After temporary successes the scheme failed. Though Duplex was a great organizer, he did not possess Clive's genius for war. The conflicts between the French and the British in India continued till 1754, when the French government, anxious to make peace, sent a special commissioner, Charles Robert Godeheu, a director of the Compagnie des Indes, with orders to supersede Duplex and, if necessary, to arrest him. Duplex's work was ruined at a blow, and he was compelled to embark for France on Oct. 12, 1754. He had spent his private fortune in the prosecution of his public policy, the company refused to acknowledge the obligation, and the government would do nothing for a man whom they persisted in regarding as an ambitious and greedy adventurer. The greatest of French colonial governors died in obscurity and want on Nov. 10,

1763. In 1741 he had married Jeanne Albert (d. 1756), widow of one of the commissioners of the company, known to the Hindus as Joannar Begum, who proved of great use to her husband in his negotiations with the native princes. Duplex defended his case against the company in his *Mémoires—contenant la compagnie de l'Inde avec les pièces justificatives* (1751), to which Godeheu replied in his *Lettre à M. Duplex* (1760).

DUPICATING MACHINES. See OFFICE APPLIANCES

DUPONT, PIERRE (1821-1870), French song writer, the son of a blacksmith, was born at Lyons on April 23, 1821. He was brought up in the country by his godfather, a village priest, and apprenticed to a notary at Lyons. In 1839 he found his way to Paris, and some of his poems were inserted in the *Gazette de France* and the *Quotidien*. Two years later he was saved from the conscription and enabled to publish his first volume, *Les Deux Anges*, through the exertions of a kinsman and of Pierre Lebrun Gounod's appreciation of his peasant song, "J'ai deux grands bœufs dans mon étable" (1846), settled his vocation as a songwriter. He had to engage Ernest Reyer to write down his airs. He sang his own songs, as they were composed, at the workmen's concerts in the Salle de la Fraternité du Faubourg Saint-Denis, the public performance of his famous *Le Pain* was forbidden, *Le Chant des ouvriers* was even more popular, and in 1851 he was condemned to seven years' exile. The sentence was cancelled and for a time Dupont renounced politics. He died at Lyons on July 24, 1870. His songs have appeared in various forms, *Chants et chansons* (3 vols., with music, 1852-1854), *Chants et poésies* (7th ed., 1862), etc. Among the best known are "Le Braconnier," "Le Tisserand," "La Vache blanche," and "La Chanson du blé."

DU PONT, SAMUEL FRANCIS (1803-1865), U.S. naval officer, was born in Bergen Point, N.J., Sept. 27, 1803. Educated in Philadelphia, Pa., young Du Pont was attracted to the naval service as a result of the exploits of U.S. sea-fighters during the War of 1812. He was appointed a midshipman in 1817, and his training was under Captain Charles Stewart in the ship-of-the-line "Franklin." He served on various naval vessels in South American and European waters, being promoted a lieutenant in 1826 and a commander in 1842. In command of the sloop of war "Cyane," on the Pacific coast at the outbreak of the Mexican War, Du Pont distinguished himself in a series of daring amphibious operations which cleared the enemy out of the Gulf of California. He participated in the capture of Mazatlán and other cities which drove the enemy from the Pacific coast of Mexico. For the next ten years Du Pont played an important part in the development of steam in the navy. In 1855 he was appointed a captain and, at the same time, brought congressional wrath upon himself as chairman of the naval efficiency board which found several hundred naval officers incompetent. As senior member of the commission of conference, Du Pont was instrumental in planning the naval strategy of the Civil War, and he carried out the first stages of that strategy, when, in the command of the south Atlantic blockading squadron, he stormed and took the Confederate forts at Fort Royal, S.C. (Nov. 7, 1861). Congressional thanks and a rear admiralcy followed the exploit, the capture of forts by ships previously having been regarded as impracticable. Eighteen months later, in a similar attempt upon the defenses of Charleston, S.C., and using a battle line of monitors and an ironclad, Du Pont met with a severe reverse. He was relieved in July 1863. A dispute with Secretary of the Navy Welles as to the responsibility for this defeat continued until Du Pont's death in Philadelphia, on June 23, 1865. Du Pont circle and fountain in Washington, D.C., were named in his honor.

See H. A. Du Pont, *Rear Admiral Samuel Francis Du Pont* (1926), *Official Records of the Union and Confederate Navies in the War of the Rebellion*, 30 vol. (1894-1922). (W. B. Ck.)

DU PONT, THOMAS COLEMAN (1863-1930), American manufacturer and statesman, was born at Louisville, Ky., Dec. 11, 1863. He was educated at the Massachusetts Institute of Technology, and entered the Kentucky coal and iron mining industries in 1883. In 1900 he removed to Wilmington, Del.,

being president 1902-15 of the E. I. du Pont de Nemours Powder company. Appointed senator in July 1921 in place of Josiah O. Wolcott, who had resigned, he failed to secure election on the Republican ticket in 1922, but was successful in 1924. He built a concrete motor highway at a cost of \$4,000,000 in the State of Delaware, and made a gift of it to the State.

His cousin, PIERRE SAMUEL DU PONT (1870-1954), having graduated from the Massachusetts Institute of Technology in 1890, engaged in manufacturing at Wilmington. He became chairman of the board of the E. I. du Pont de Nemours Powder company and also chairman of the General Motors Corporation. The E. I. du Pont company, which originally confined its activities to the making of explosives, under his guidance engaged in the manufacture of artificial silk, motion-picture films, paints and varnishes.

DUPONT, an anthracite mining borough of Luzerne county, Pa. U.S.A., half way between Scranton and Wilkes Barre, on the Lackawanna and Wyoming Valley railroad. The population in 1950 was 4,107 and it was 5,278 in 1940.

DUPONT DE L'ETANG, PIERRE ANTOINE, COUNT (1765-1840), French general, born at Chabanais on July 4, 1765, first saw active service as a member of Maitlebois' legion in Holland, and in 1791 was on the staff of the Army of the North under Dillon. He rose rapidly, and in the campaign of 1800 he was chief of the staff to Berthier. After the battle of Marengo he defeated the Austrians at Pozzolo. In the campaign on the Danube in 1805, as the leader of one of Ney's divisions, he prevented the escape of the Austrians from Ulm, and so contributed to the subsequent capture of Mick and his whole army (see NAPOLEONIC CAMPAIGNS). At Friedland he won further fame. He entered Spain in 1808 at the head of a corps. After the occupation of Madrid, Dupont, newly created count by Napoleon, was sent to subdue Andalusia but had to retire on the passes of the Sierra Morena. Pursued and cut off by the Spanish army under Castaños, his corps was defeated and capitulated (Baylen, July 19-23; see PENINSULAR WAR). His troops were for the most part poor lawes, and ill luck contributed materially to the catastrophe, but Dupont was deprived of his rank and title, and imprisoned from 1812 to 1814. On April 3, 1814, his nomination as minister of war was confirmed by Louis XVIII but his portfolio was removed from him on Dec. 3, owing to his incompetence. Appointed commander of the 22nd military division, he lost his post at the return of Napoleon, but after Waterloo recovered it. After the Second Restoration he was a member of the *conseil privé* of Louis XVIII. From 1815 to 1830 he was deputy for the Charente. He lived in retirement from 1832 till his death in Paris on March 8, 1840.

Amongst the writings Dupont left are some poems, including *L'Art de la guerre* (1838), and verse translations from Horace (1836), and some military works.

See Lieut-Col Tilius, *Le Général Dupont une erreur historique* (1903).

DUPONT DE L'EURE, JACQUES CHARLES (1767-1835), French lawyer and statesman, was born at Neubourg, Eure, in Normandy, on Feb. 27, 1767. In 1789 he was an advocate at the parlement of Normandy. In 1798 he was a member of the Council of Five Hundred, and in 1813 he became a member of the Corps Législatif. During the Hundred Days he was vice president of the chamber of deputies, and when the allied armies entered Paris he was one of the commissioners to negotiate with the allied sovereigns. From 1817 till 1849 he was uninterruptedly a member of the chamber of deputies, acting consistently with the liberal opposition. For a few months in 1830 he held office as minister of justice, but resigned before the close of the year and resumed his place in the opposition. At the revolution of 1848 Dupont de l'Eure was made president of the provisional assembly as being its oldest member. He died at Rouge-Peniers, Eure, on Mar. 2, 1855. His fidelity to the cause of constitutional Liberalism won for him the name of the Aristides of the French tribune.

DU PONT DE NEMOURS, PIERRE SAMUEL (1739-1817), French economist and statesman, one of the founders of the school of "Physiocrats," was born at Paris on Sept. 14, 1739.

He became intimate with François Quesnay, Turgot and other leaders of the school known as the "economists" and advocated their doctrine of free trade in his *Exportation et importation des grains* (1764). The Physiocratic school (*q.v.*) took its name from du Pont's treatise, *Physiocratie, ou constitution naturelle du gouvernement le plus avantageux au genre humain* (1768). An admirably clear expression of the doctrine is given in his *De l'origine et des progrès d'une science nouvelle* (1767). Du Pont aided Turgot during his brief period of office (1774-76). He was recalled from retirement by Vergennes in 1782 to negotiate with the English commissioner James Hutton, for recognition of the independence of the United States (1783), and to prepare a treaty of commerce with Great Britain (1786). Under Calonne he became councillor of state, and was appointed commissary general of commerce.

Du Pont was a member of the states general, and then of the constituent assembly, of which he was elected president on Oct. 16, 1790. But after Aug. 10, 1793 when he took the side of the king, he was driven into hiding. He was eventually arrested and imprisoned in La Force (1794). The death of Robespierre saved him from the guillotine. As a member of the Council of Five Hundred, du Pont was a leader of the reaction. After the republican triumph on the 18th Fructidor (Sept. 4, 1797), his house was sacked by the mob, and in 1799 he emigrated to the United States.

Jefferson requested him to prepare a scheme of national education, which was published in 1800 under the title *Sur l'éducation nationale dans les Etats Unis d'Amérique*. Though the scheme was not carried out in the United States, several of its features have been adopted in the existing French code. On his return to France in 1802 he was elected to the *Institut*. In 1814 he was secretary to the provisional government, and on the restoration he was made a councillor of state. In 1815 he returned to the United States, and died at Eleutherian Mills near Wilmington, Del., on Aug. 6, 1817.

The powder mills founded by his son Eleuthère at Wilmington brought the family considerable wealth. Du Pont's grandson, Admiral Samuel Francis du Pont (1803-65), played a conspicuous part as a U.S. naval officer in the American Civil War.

See Schelle, *Du Pont de Nemours et l'école physiocratique* (1888).

DU PONT DE NEMOURS AND COMPANY, E. I., organized in 1802 as a gunpowder company, later developed into a world known chemical manufacturing corporation with (in 1951) 72 plants in 25 states of the United States. Among the products of the company are commercial explosives acids, tetra ethyl lead, sodium, synthetic ammonia, industrial alcohol, dyes, lacquers, paints pigments, coated fabrics, rayon, nylon "Orlon" acrylic fibre and other synthetic fibres, cellulose film, photographic film and plastics. Its commercial explosives have helped to build canals, railroads, highways and tunnels, and to extract coal, oil and minerals. Its dyes, nitrogen products, synthetic camphor, neoprene chemical rubber and nylon have contributed importantly to the nation's self sufficiency. Its military explosives have served the nation's wartime needs since 1802, but at the termination of hostilities it has always quickly returned to peacetime production. In peacetime, military explosives make up only a small fraction of 1% of the company's business. Headquarters are at Wilmington, Del., the site of the original powder plant, long since abandoned, built by Eleuthère Irénée du Pont de Nemours, its founder, who had learned to manufacture powder under the renowned French chemist Antoine Lavoisier.

(L. D. P.)

DU PONT HIGHWAY see COLEMAN DU PONT ROAD

DUPONT, JAMES (1606-1679), English classical scholar, was born in Cambridge. In 1639 he was appointed regius professor of Greek there, in 1664 dean of Peterborough and in 1668 master of Magdalen college. Throughout the Civil War, in spite of the loss of his clerical offices and eventually of his professorship, Dupont continued his lectures. He is best known by his *Homeric gumologia* (1660), a collection of the aphorisms in the *Iliad* and *Odyssey*, illustrated by quotations from the Bible and classical literature. His other published works chiefly consist of translations (from the Bible and Prayer Book into Greek) and short original poems (*Horae subsecivae* or *Stromata* and *Sylvae*).

Duport did much to keep alive the study of classical literature in his day

The chief authority for the life of Duport is J. H. Monk's "Memoir" (1825), see also Sandys, *Hist. Class. Schol.* (1908), II 349

DUPPLIN MOOR, scene of the battle of Dupplin, Aug. 9, 1332. This battle is of importance not only as the turning point in the Scottish Wars but as the birthplace of the tactics which gained the English victories later against France in the Hundred Years War (q.v.). The series of defeats suffered by Edward I in Scotland, and the initial failure of Edward III, had led to the Peace of Northampton. As a consequence, the Scottish supporters of the Plantagenets were disinherited, but, headed by Edward Baliol and Henry de Beaumont, they organized an expedition to regain their fiefs. Edward III, bound by the treaty, not merely refused help but prohibited them from crossing the border. Not to be balked, they collected a small force of English archers and men at arms, hired ships, and, sailing from Ravenspur, landed at Kinghorn in Fife. Thence they marched on Perth but were met at the river Earn by a large Scottish army under the earl of Murr. Trying to discount their inferiority by the use of surprise, the "disinherited" crossed the river under cover of darkness and made an audacious night onslaught on the rear of the Scottish camp. But this only affected part of the enemy's bivouac, and at daybreak the main force moved out in battle order to swamp their puny adversary. The "disinherited" fell back to the slopes of Dupplin murr, and there the knights and men-at-arms dismounted to form a phalanx of spears, while the archers spread out in a dispersed line amid the heather on either flank. Only 40 men at arms were kept mounted as a reserve. The Scottish, all dismounted according to their custom, charged direct at the opposing men-at-arms, disregarding the archers. Once spears were locked the charge lost impetus and the archers, closing in from either side, poured a hail of arrows into the press, which grew ever denser until the close locked mass became help less to use their weapons. Held in front and galled on both flanks, those who could, broke away and fled, pursued by the "disinherited" horse, and those in the centre fell easy victims.

DU PRAT, ANTOINE (1463-1535), chancellor of France and cardinal, was born at Issore on Jan. 17, 1463. He began life as a lawyer, and rose rapidly in the legal hierarchy owing to the influence of his cousin Antoine Bohier, cardinal archbishop of Bourges. In 1507 he became first president of the parlement of Paris. Louise of Savoy had employed him as her adviser in her affairs, and had made him tutor to her son. When Francis I ascended the throne he made Du Prat chancellor of France. During the regency of Louise of Savoy he, together with Florimond Robertet, was at the head of affairs. After the death of his wife in 1507 Du Prat had taken orders, he received the bishoprics of Valence, Dia, Meaux and Albi, and the archbishopric of Sens (1525), in 1527 he became cardinal, and in 1530 papal legate. He was a determined adversary of the Reformation. He died at Nantouillet on July 9, 1535.

See the marquis Du Prat, *Vie d'Antoine Du Prat* (1857)

DUPRE GIOVANNI (1820-1885), Italian sculptor, born in

a more ideal conception of form contrasting with the naturalism of his early period. Among his later work we may mention a 'Pieta' in the cemetery of Siena, executed for the Bichi-Ruspoli family and the monument of Cavour in Turin. His realistic treatment of form here seems to conflict with the allegorical elements of the composition. Dupre also executed many portrait busts. He died in Florence on Jan. 10, 1882.

His autobiography *Pensieri sull'Arte e i Ricordi Autobiografici* (1882) was translated into English by Peruzzi.

DUPRÉ, JULES (1811-1889), French painter, and one of the chief members of the Barbizon group of romantic landscape painters, was born at Nantes, and died at L'Isle Adam, Oct. 6, 1889. If Corot stands for the lyric and Rousseau for the epic aspect of the poetry of nature, Dupré is the exponent of her tragic and dramatic aspects. He was the son of a porcelain manufacturer and started his career in his father's works, whence he went to his uncle's china factory at Sèvres. Dupré exhibited first at the Salon in 1831, and three years later was awarded a second class medal. In the same year he came to England, where he was deeply impressed by the genius of Constable. From him he learnt how to express movement in nature, and the district of Southampton and Plymouth, with its wide, unbroken expanses of water, sky and ground, gave him good opportunities for his special gifts. Late in life he changed his style, and gained appreciably in largeness of handling and arrived at greater simplicity in his colour harmonies. Among his best known works are the "Morning" and "Evening" at the Louvre, the early "Crossing the Bridge" in the Wallace collection, and the "River Scene" now in the Tate Gallery, London.

See Jules Claretie, *Peintres et sculpteurs contemporains* (2nd series, 1884).

DUPUIS, CHARLES FRANÇOIS (1742-1809), French author and politician, was born of poor parents at Trye-Chateau, near Gisors. He represented Seine-et-Oise in the Convention, was secretary to the Assembly in An III and a member of the Council of Five Hundred in An IV. After the 18th Brumaire he was a member of the Legislative Body, eventually becoming its president. In 1781 he had published a memoir on the origin of the signs of the zodiac, which he placed in Upper Egypt, and on the connection with the whole fabric of the mythology of the ancients. His chief work, *Origine de tous les cultes* (3 vols., 1795), developing his theories, aroused a bitter controversy, and was one of the factors which led Napoleon to send a scientific expedition to Upper Egypt. The *Origine* passed through many editions (modern ed. 1876), and the author himself published an abridged edition in 1798. Dupuis died on Sept. 29, 1809.

DUPUY, CHARLES ALEXANDRE (1815-1923), French statesman, born at Le Puy (Haute Loire) on Nov. 5, 1815. In 1885 he was elected to the chamber as an Opportunist Republican, and became minister of public instruction in Ribot's cabinet, in 1892. In April 1893 he formed a ministry himself, but resigned at the end of November, and on Dec. 5 was elected president of the chamber. During his first week of office the anarchist Vaillant, who had gained admission to the chamber, threw a bomb at the president, and M. Dupuy's collected bearing, and his historic words "Messieurs, la séance continue," gained him much credit. In May 1894 he again became premier and minister of the interior, and he was by President Carnot's side when the latter was assassinated at Lyons in June. His cabinet remained in office till January 1895, it was under it that Captain Dreyfus (q.v.) was arrested and condemned (Dec. 23, 1894). In November 1898, after Brisson had at last remitted the case to the judgment of the court of cassation, Dupuy formed a cabinet of Republican concentration. It was no sooner discovered that the judges were likely to decide in favour of Dreyfus than Dupuy proposed a law in the chamber transferring the decision to a full court of all the divisions of the court of cassation. This arbitrary act, though adopted by the chamber, was at once construed as a fresh attempt to maintain the judgment of the first court martial, but the whole court of cassation decided that there must be a new court-martial, and Dupuy at once resigned (June 1899). In June 1900 he was elected senator for the Haute-Saône. He died in 1923.

(1845, Arcades of the Uffizi, Florence) The mourning Sappho (1857) is his most famous work of this period. His success was due to his lifelike and original interpretation of form at a time when Italian sculpture was deteriorating into a mannered imitation of Canova. A visit in 1856 to Naples and Rome, where he admired Canova's monument to Pius VI, influenced him towards

DUPUY, PIERRE (1582-1651), French scholar, otherwise known as *Puteanus*, was born at Agen (Lot-et Garonne). In 1615 he was commissioned by Mathieu Mole, first president of the parlement of Paris, to catalogue the "Trésor des chartes." His ms inventory is preserved in the original and in copy in the Bibliothèque Nationale, and transcriptions are in the national archives in Paris, at the record office in London, and elsewhere. Dupuy and his brother then bought from Rigault the post of keeper of the king's library, and drew up a catalogue of the library. He was author of some important books, written from the Gallican standpoint, on the history of the relations of Church and State in the middle ages. Dupuy died in Paris on Dec. 14, 1651.

DUPUY DE LÔME, STANISLAS CHARLES HENRI LAURENT (1816-1885), French naval architect, the son of a retired naval officer, was born at Ploemeur, near Lorient, on Oct. 15, 1816. He entered the École Polytechnique in 1835, and in 1842 was sent to England to study and report on iron ship-building. Acting on his report, which was published in 1844, the Government built their first iron vessels under his supervision. He planned and built the steam line of battle ship "Napoleon" (1848-1852), and devised the method of altering sailing ships of the line into steamers, which was afterwards extensively practised in both France and England. He also showed the practicability of armouring the sides of a ship, and the frigate "Gloire" gave a very clear demonstration of his views. It was the beginning of a great change in the construction of ships. At the beginning of the Franco-German War Dupuy sat on the committee of defence, and during the siege of Paris planned a steerable balloon, for carrying out which he was given a credit of 40,000 fr., but the balloon was not ready till a few days before the capitulation. In 1877 he was elected a senator for life. He died in Paris on Feb. 1, 1885.

DUQUE DE ESTRADA, DIEGO (1589-1647), Spanish memoir writer, soldier and adventurer, was born at Toledo. He left a book of amazingly vivid memoirs, entitled *Comentarios de el Desengañado de sí Mismo, prueba de todos estados, y elección del Mejor de ellos*—"The Commentaries of one who knew his own little worth, the touchstone of all the states of man, and the choice of the best."

The memoirs have been reprinted by Don Pascual de Gayangos in the *Memorial histórico español*, vol. xii (1860).

DUQUESNE, ABRAHAM, MARQUIS (1610-1688), French naval officer, was born at Dieppe in 1610. He spent his youth in the merchant service, and captured the island of Lerins from the Spaniards in May 1637. About the same time his father was killed in an engagement with the Spaniards, and the news raised his hatred of the national enemy to the pitch of a personal and bitter animosity. He distinguished himself in the engagement at Guebara (1638), the expedition to Corunna (1639) and in battles at Tarragona (1641), Barcelona (1643) and the Cabo de Gata. Serving as a volunteer in the Swedish service in 1643, he defeated the Danish fleet near Gothenburg and thus raised the siege of the city. The Danes returned to the struggle with increased forces under the command of King Christian in person, but they were again defeated—their admiral being killed and his ship taken. On the conclusion of peace between Sweden and Denmark in 1645, Duquesne returned to France. The revolt at Bordeaux, supported as it was by material aid from Spain, gave him the opportunity of at once serving his country and gratifying his long cherished hatred of the Spaniards. In 1650 he fitted out at his own expense a squadron with which he blockaded the mouth of the Gironde, and compelled the city to surrender. Peace with Spain was concluded in 1659, and Duquesne was then occupied in suppressing piracy in the Mediterranean. On the revolt of Messina from Spain, he was sent to support the insurgents, and encountered the united fleets of Spain and Holland under the command of de Ruyter. After several battles, in which the advantage was generally on the side of the French, a decisive engagement took place near Catania (April 20, 1676), when the Dutch fleet was totally routed and de Ruyter mortally wounded. The greater part of the defeated fleet was

afterwards burned in the harbour of Palermo, where it had taken refuge, and the French thus secured the undisputed command of the Mediterranean. For this service Duquesne received a letter of thanks from Louis XIV. together with the title of marquis and the estate of Bouchet. His last achievements were the bombardment of Algiers (1682-83), to effect the deliverance of the Christian captives, and the bombardment of Genoa in 1684. He retired from service in 1684, on the ground of age and ill health. It is probable also that he foresaw the revocation of the Edict of Nantes, which took place in the following year. He died in Paris on Feb. 2, 1688.

See Jal, *Abraham Duquesne, et la marine de son temps* (1873).

DUQUESNE, a city of Allegheny county, Pa., U.S., on the Monongahela river, 12 mi. S.E. of Pittsburgh, served by the Pennsylvania railroad. The population was 17,612 in 1950 and was 20,693 in 1940 by the federal census. It is an important steel-manufacturing centre, with a total production in 1950 of about 1,323,000 net tons of pig iron and ferromanganese and 1,843,000 net tons of ingots. Rolled products of semfinished steel, concrete reinforcement bars and other bars, and tube rounds are also manufactured. Duquesne was settled in 1885, incorporated as a borough in 1891 and chartered as a city in 1917.

DU QUOIN, a city of Perry county, Ill., U.S., in the fertile agricultural and coal mining region southeast of St. Louis, on federal highway 51 and state highways 153 and 154 and the Illinois Central railroad. The population was 7,139 in 1950 and was 7,515 in 1940 by the federal census. It is a shipping point for coal, grain, livestock, fruit and the home of the Du Quoin state fair and Egyptian music camp. Its manufacturing industries include machine shops, a dairy and bottling and a meat packing plant. The largest strip coal mines in the country are there. The community of Old Du Quoin was settled in 1816, and the present city was laid out 5 mi. E.

DURALUMIN. An aluminum alloy discovered by A. Wilm and originally made at Duren in Germany. It possesses the valuable property of being greatly strengthened by heat treatment, as steel is hardened by quenching and tempering. In addition to 94% aluminum, 4% of copper and 1% of manganese, duralumin contains 1% of magnesium and owes its special qualities to the association of the last named component with the silicon always present in aluminum as an impurity. (For a brief explanation see *ALUMINUM Alloys of Aluminum*.) The original composition has been varied, manganese being sometimes eliminated and sometimes replaced by iron, nickel or chromium, but magnesium and silicon remain as essential constituents, while copper, which itself confers somewhat similar properties on aluminum, is also generally retained. Special trade names have been applied to some of these later alloys and the whole class is now frequently known as the "strong aluminum alloys."

In the normal state these alloys are soft and ductile and may be rolled into sheets and bars or drawn into tubes, angles, etc. Such work hardens them, as all metals, but leaves them like many aluminum alloys, unduly subject to corrosion. Annealing at about 400° C. removes this "work hardness," but if the alloys be heated to temperatures which vary with the alloy and its intended use from 450° C. to 550° C. and are then plunged into water, although at first softened and, therefore, still capable of being worked, hardening soon commences and continues for several days. By reheating at about 200° C. the hardening process can be hastened.

Heat-treated duralumin is comparatively resistant to corrosion. It is ductile (elongation 8% to 15%), will bear a load of 30,000 lb. per square inch without permanent distortion and breaks under a load of 55,000-62,000 lb. per square inch.

As the alloys are light (specific gravity = 2.85) their strength per unit of weight (specific tenacity) is high (9.3) compared with nickel steel (5.9) and nickel chrome steel (7.2). The properties make them particularly suitable for aircraft construction, for which they have been used to a very great extent. It may be said that the development of the rigid airship would have been impossible without duralumin, used throughout for the framework of these gigantic craft, while all-metal heavier-than-air machines also depend on these alloys. Connecting rods of duralumin find favour for internal-

combustion engines, while an alloy in which nickel replaces manganese (Y alloy) is used for the pistons of the large diesel engines of submarines, for which it is particularly suited, because it can be cast to shape and retains its strength at comparatively high temperatures.

Like aluminum and its other alloys, duralumin cannot be effectively soldered since joints so made corrode rapidly nor can it be welded without losing the special properties to which it owes its utility.

To all ordinary fabricating processes as spinning, pressing, riveting, machining, etc., duralumin lends itself perfectly.

For a full account of these alloys see R. J. Anderson *The Metallurgy of Aluminum and Aluminum Alloys* (1925), where an extensive bibliography will be found. (R S)

DURAN, a Jewish Provençal family of rabbis and scholars, of whom the following are the most important —

1. **PROFIAT DURAN**, called also **EPHOD**.

He was in 1391 compelled to profess Christianity, but remained devoted to Judaism. His chief works were grammatical and philosophical. In the former realm his most important contribution was the *Ma'aseh Ephod* (completed in 1403), in the latter, his commentary to the *Guide of the Perplexed* by Maimonides (q v).

2. **SIMON BEN ZEMAH DURAN** (1361–1441), rabbi of Algiers. He was one of the first of the medieval rabbis to be a salaried official of the synagogue. Before the 14th century the rabbinical post had been almost invariably honorary, and filled by men who derived their income from a profession, especially medicine. Duran wrote a systematic work on theology, *Magen Aboth*, but is chiefly famous for his numerous *Responsa* (known as *Tashbaas*), published in 1738–39, which gives valuable information as to social and religious conditions of his day. (I A)

DURAN, AGUSTIN (1793–1862), Spanish scholar, was born at Madrid, where his father was court physician. He was sent to the seminary at Vergara. He studied philosophy and law at the University of Seville, and was admitted to the bar at Valladolid. He held a post in the education department at Madrid (1821–23), but was suspended because of his political opinions. In 1834 he became secretary of the board for the censorship of the press, and shortly afterward obtained a post in the national library at Madrid. The revolution of 1840 led to his dismissal, but he was reinstated in 1843, and in 1854 was appointed chief librarian, he retired, however, in the following year. In 1838 he published anonymously his *Discurso sobre el influjo que ha tenido la crítica moderna en la decadencia del teatro antiguo español*, which greatly influenced the younger dramatists of the day. He next endeavored to interest his fellow countrymen in their ancient, neglected ballads, and in the forgotten dramas of the 17th century. His *Romancero general* was published in five volumes (1828–32, later ed. 2 vol., 1849–51), *Talla española* (1834) is a reprint of old Spanish comedies. Durán's *Romancero general* is the fullest collection of the kind.

DURANCE (anc. *Druentia*), one of the principal rivers draining the French slope of the Alps towards the Mediterranean. Its total length from its source in the High Alps of Dauphiné to its junction with the Rhone, a little below Avignon, is 217½ miles. It is commonly said to take its origin in some small lakes a little south of the Mont Genève pass, but has two other head streams of much greater length and volume. These are the Claire, flowing in from the north, through the smiling Névache glen, at the head of which, not far from the foot of the Mont Thabor (10,440 ft.) it rises in some small lakes, on the east side of the Col des Rochilles, and the Gussane (flowing in from the north west and rising near the Col du Lautaret, 6,808 ft.). Between its junction with the Cervyrette and the Gyrondé the Durance passes through fine deeply-cut gorges. It then runs through a stony plain, where it frequently overflows and causes great damage, this being indeed the main characteristic of the Durance throughout its course. At the foot of the fortress of Mont Dauphin and some distance above the town of Embrun, it receives (left) the Guil, which flows through the Queyras valley from near the foot of Monte Viso. It becomes the boundary for a while between the

departments of the Hautes Alpes and of the Basses Alpes, and receives the considerable Ubaye river, flowing from near the foot of Monte Viso past Barcelonnette (left).

Flowing through the Basses-Alpes it is joined above Sisteron (right) by the wild torrent of the Buech, flowing from the desolate region of the Devoluy, the Bleone (left) (on which Digne, the capital of the department, is situated) and the Asse (left). The Verdon, flowing past the town of Castellane, joins it from the lower summits of the Maritime Alps. After passing through some narrow gorges near Sisteron the bed of the river becomes wide and liable to flood, the frequent overflows being kept within bounds by numerous dykes and embankments. These features are especially marked when the river, after leaving the Basses-Alpes, bends north west and, always serving as the boundary between the departments of Vaucluse (north) and of the Bouches-du-Rhône (south), passes Cavaillon above its junction with the Rhone. The drainage area of the Durance is about 5,166 sq. m., while the height it descends is 6,550 ft., if reckoned from the lakes on the Mont Genève, or 7,850 ft. if we take those at the head of the Névache valley as the true source of the river.

DURAND, ASHER BROWN (1796–1886), American painter and engraver, was born at South Orange (N. J.), on Aug. 21, 1796. He worked with his father, a watchmaker, was apprenticed, in 1812, to an engraver named Peter Maverick, and his first work, the head of an old beggar after Waldo, attracted the attention of the artist Trumbull. Durand established his reputation by his engraving of Trumbull's "Declaration of Independence." After 1835, however, he devoted himself chiefly to portrait painting. He painted several of the presidents of the United States and many other men of political and social prominence.

In 1840 he visited Europe, where he studied the work of the old masters, after his return he devoted himself almost entirely to landscape. He died at South Orange on Sept. 17, 1886. He was one of the founders of the National Academy of Design in 1826, and was its president in 1845–61. Durand may be called the father of the Hudson River school. Although there was something hard and unsympathetic about his landscapes and unnecessary details and trivialities were over prominent, he was a well trained craftsman, and his work is marked by sincerity.

DURAND, GUILLAUME (DURANTI or DURANTIS) (c. 1230–1296), French canonist and liturgical writer, and bishop of Mende, was born at Pumiisun, near Beziers. He studied law at Bologna, and about 1264 was teaching canon law at Modena. Clement IV. called him to the pontifical court as a chaplain and auditor of the palace, and in 1274 he accompanied Gregory X. to the Council of Lyons, the constitutions of which he helped to draw up. Martin IV. made him vicar general in 1281, then governor of Romagna and of the March of Ancona (1283). In the midst of the struggles between Guelphs and Ghibellines, Durand successfully defended the papal territories, both by diplomacy and by arms. Honorius IV. retained him in his offices, and although elected bishop of Mende in 1286, he remained in Italy until 1291. In 1295 he refused the archbishopric of Ravenna, and in 1296 retired to Rome, where he died on Nov. 1.

Durand's principal work is the *Speculum judicale*, which was drawn up in 1271, and revised in 1286 and 1291 (best ed. Turin, 1578). It is a general explanation of civil, criminal and canonical procedure, and also includes a survey of the subject of contracts. It is a remarkable synthesis of Roman and ecclesiastical law, distinguished by its clarity, its method, and especially its practical sense, in a field in which it was pioneer, and its reputation was as lasting in the courts as in the schools. His *Rationale divinarum officiorum*, on the origin and symbolic sense of the Christian ritual, written before 1286, is one of the authorities on the Western liturgy (latest ed. Naples, 1866). The other important works of Durand comprise a *Repertorium juris canonici* (*Breviarium aureum*), a collection of citations from canonists on questions of controversy, a *Commentarius in sacrosanctum Lugdunense concilium* (ed. 1569), of especial value owing to the share of Durand in the elaboration of the constitutions of this council (1274), and inserted by Boniface VIII. in the *Sextus*.

Durand's nephew, also named **GUILLAUME DURAND** (d. 1330),

and also a canonist, was rector of the university of Toulouse and succeeded his uncle as bishop of Mende. He wrote in 1311, in connection with the council of Vienne, *De modo celebrandi concilii et corruptelis in Ecclesia reformandis*.

On the elder Durand see V. Leduc in *Histoire littéraire de la France*, vol. xx, pp. 411-497 (1842); Schulte, *Geschichte der Quellen des canonischen Rechts* (1877); E. Male, *L'Art religieux au XIII^e siècle en France* (1898). On the nephew see B. Hauréau, in *Journal des savants* (1892).

DURAND, GUILLAUME (DURANDUS OF ST. POURSAIN) (d. 1332), French scholastic theologian known as *Doctor Resolutorius*, was born at St. Pourçain, Auvergne. He entered the Dominican order at Clermont and in 1313 was made a doctor in Paris, where he taught till Pope John XXII called him to Avignon as master of the sacred palace, i.e., theological adviser and preacher. He subsequently became bishop of Limoux (1317), of Le Puy (1318) and of Meaux (1326). He composed a commentary on the *Sentences* of Peter Lombard (Paris, 1508, etc.), in which, breaking with the moderate realism of Aquinas, he anticipated the terminology of William of Occam. Singularity alone exists in things and is known immediately by the intellect. From this it follows that the active intellect which is supposed to abstract universals, is superfluous and the problem of individuation absurd. Durand also denied a distinction between essence and existence and opposed the realms of reason and faith. In the question of the beatific vision, arising out of opinions promulgated by John XXII (q.v.), he sided with Thomas Walleis, Armand de Belloc and the doctors of Paris against the pope, and composed his *De statu animarum sanctarum*. Mention should also be made of his *De jurisdictione ecclesiastica et de legibus* (Paris, 1506).

See B. Hauréau, *Histoire de la philosophie scolastique* (1880); C. Werner, *Die Scholastik des späten Mittelalters*, vol. II (1883); J. Koch, *Durandus de S. Porciano* O.P. (Münster, 1927).

DURANDO, GIACOMO (1807-1894), Italian general and statesman, was born at Mondovì in Piedmont. He was implicated in the revolutionary movements of 1831 and 1832. In 1848 he was one of those who asked King Charles Albert for the constitution. On the outbreak of the war with Austria he commanded the Lombard volunteers, and in the campaign of 1849 he was aide-de-camp to the king. He was elected member of the first Piedmontese parliament and was a strenuous supporter of Cavour, during the Crimean campaign he took General La Marmora's place as war minister. In 1855 he was nominated senator, lieutenant general in 1856, ambassador at Constantinople in 1859 and minister for foreign affairs in the Rattazzi cabinet two years later. He was president of the senate from 1884 to 1887, after which year he retired from the army.

His brother, GIOVANNI DURANDO (1804-1869), also spent his early life abroad. Returning to Italy on the outbreak of the revolution of 1848, he was appointed commander of a division of the pontifical forces and fought against the Austrians in Venetia until the fall of Vicenza, when he returned to Piedmont as major general. In the campaign of 1849 he commanded the first Piedmontese division, he subsequently served in the Crimea, in the war of 1859, and in that of 1866 as commander of the 1st army corps.

DURANGO, a city of southwestern Colorado, U.S., 6,525 ft above sea level, the county seat of La Plata county. It is on federal highways 160 and 350 and is served by the Denver and Rio Grande Western and the Rio Grande Southern railways. The population was 7,458 in 1930 and 5,887 in 1940 by the federal census.

Durango is the trading centre of a wide area, with livestock, fruit, oil, natural gas, mining and lumbering the main industries. Durango National forest (3,000,000 ac.) is 12 mi N. of the city, 60 mi W. is Mesa Verde National park, containing the most notable prehistoric cliff dwellings in the United States. At Hesperus (8 mi W.) is the Fort Lewis school of agriculture, a branch of the state agricultural college. The city was incorporated in 1880, four years after Colorado was admitted to statehood.

DURANGO, a state in north central Mexico, bounded north by Chihuahua, east by Coahuila, south by Nayarit, west by Sinaloa,

with an area of 47,679 sq mi. Pop. (1950) 629,502, including fewer than 600 Indians. On a high, semiarid plateau, Chihuahua is extremely mountainous in its westward districts where the Sierra Madre Occidental courses in a series of peaks between 7,000 and 10,000 ft high. Rainfall in the eastern sections is sparse and agriculture depends exclusively on irrigation; stock raising and minor forest industries occur in the west. Coursing eastward from the Sierra, the Nazas river is the largest of the state flowing for approximately 375 mi., when swollen by spring rains it is the main source of water that permits commercial crops of cotton, wheat, maize, tobacco, sugar cane, vegetables and fruits. Durango shares with Coahuila the famous Laguna cotton district, a large co-operative enterprise. The state is highly mineralized and mining has traditionally been a principal mainstay. Silver, gold, sulphur, tin, coal, cinnabar and other valuable deposits exist, only partially known. A colossal helmet shaped hill 700 ft high of nearly pure iron, known as Cerro de Mercado, rises 2 mi from the capital, Durango city. The hill is estimated to contain between 300,000 and 600,000 tons of haematite in various stages of oxidation, forced out by ancient volcanic action. It supports the iron and steel works near by. The Candelaria mine (argenteite) is famous for its prodigious output and purity of ore. Other mining districts are Mapimi, a great arid depression 130 mi N.N.E. of Durango city, Cuernavaca, Nombre de Dios (first Spanish settlement, c. 1555), Papasquaro, and San Juan del Rio. Expensive and inadequate transportation has hampered development of mineral resources. National Railways of Mexico lines traverse the state northeast to southwest, and another line crosses its eastern parts. In 1951 construction began on a direct rail connection from Durango city to the Pacific port of Mazatlán. The state is also crossed by two branches of the Pan American paved highway and has air routes. Originally explored by Francisco de Ibarra (1562-63), Durango shared the colonial history of Chihuahua as major parts of the realm of Nueva Viscaya, the two became sovereign and separate states in 1823. As frontier zones, they were plagued by Indian uprisings until late in the 19th century. Principal places in Durango, with their 1940 populations, include the only city and state capital, Durango (33,412), Guanacachi (2,512), El Oro (1,860), San Juan de Guadalupe, San Dumas, and Villa Lerdo. The latter is a suburb of Torreon, Coahuila. (Hd C.)

DURANGO, also called VICTORIA DE DURANGO, a city of Mexico, capital of the state of Durango, 574 mi N.W. of Mexico City, in lat. 24° 25' N., long. 105° 55' W. Pop. (1940) 33,412, (est. 1950) 61,000. Durango lies on the main trunk highway from the federal capital to the United States border at Ciudad Juárez. El Paso, Tex., and is served by National Railways of Mexico, in 1951 construction began on a rail link to the Pacific port of Mazatlán. At an altitude of 6,314 ft the city dominates the picturesque and fertile Guadiana valley formed by eastern spurs of the Sierra Madre. Its climate is mild and healthful, and the city is provided with abundant water supply, thermal springs are found near by. An outstanding feature is the Cerro de Mercado north of the city, it is a solid hill of iron that represents one of the world's largest deposits. Durango is an important commercial and mining centre with diversified local industries, iron, steel, reduction works, cotton and woolen mills, glass works, iron

DURANT

San Francisco and the Kansas, Oklahoma and Gulf railways. Pop. (1950) 10,521. Oklahoma Southeastern State college and Oklahoma Presbyterian college are located in Durant. There is a large state fish hatchery.

DURANTE, FRANCESCO (1684–1755), Italian composer, was born at Frattamaggiore, in the kingdom of Naples, on March 15, 1684. At an early age he entered the Conservatorio dei poveri di Gesù Cristo, at Naples, where he received lessons from Gaetano Greco, later he became a pupil of Alessandro Scarlatti at the Conservatorio di Sant' Onofrio. He is also supposed to have studied under Pasquini and Pitoni in Rome, but no documentary proof of this statement can be given. He is said to have succeeded Scarlatti in 1725 at Sant' Onofrio, and to have remained there until 1742, when he succeeded Porpora as head of the Conservatorio di Santa Maria di Loreto, also at Naples. This post he held for 13 years, till his death on Aug. 13, 1755, at Naples. His fame as a teacher was all but unrivalled, and Jommelli, Paisiello, Pergolesi, Piccini and Vinci were among his pupils. A complete collection of Durante's works, consisting all but exclusively of sacred compositions, was presented by Selvaggi, a Neapolitan lover of art, to the Paris library. The imperial library of Vienna also preserves a valuable collection of Durante's manuscripts. Two requiems, several masses (one of which, a most original work, is the *Pastoral Mass* for four voices) and the *Lamentations* of the prophet Jeremiah are among his most important settings.

DURAO, JOSÉ DE SANTA RITA (c. 1737–1784), Brazilian poet, was born in the parish of Cata Preta, near the boundary of Minas Geraes, Brazil, probably in 1737, though some authorities place his birth within the years 1718–22. He received his early education at the Jesuit college in Rio de Janeiro, and in 1756 obtained the degree of doctor of theology from the historic University of Coimbra, Portugal. Two years later he entered the Gratian convent of the order of St. Augustine. Famous already as a preacher, he offended his superiors by his liberality of thought, and particularly by his openly expressed regard for the proscribed Jesuits. In consequence he was forced to leave the country. He was detained in Spain as a spy in 1762, but was released in the following year, and then went to Rome, where he became acquainted with Alfieri, Pindemonte, Casti and other literary men of the time. In 1778 he returned to Portugal to accept the chair of theology at the University of Coimbra, and at the opening of the university for the year delivered an address in Latin, *De sapientia*, which marked him as one of the foremost intellectuals of his day. He soon returned, however, to the Gratian convent, and became its prior. In 1781 he published in Lisbon his great epic *Caramuru poema épico do descobrimento da Bahia*, a poetic treatment in ten cantos of the discovery of Bahia (southern Brazil), by Diego Alvarez. This is one of the masterpieces of Brazilian literature, and is remarkable especially for the beauty of its descriptions of South American scenery and Indian life. Failure of the poem to command instant recognition embittered its author, and led him to burn nearly all his other works. A French translation of the *Caramuru* appeared in Paris in 1829. He died in Lisbon on Jan. 24, 1784.

DURATION AND TIME are commonly used as synonymous terms. In recent philosophy, however, great stress has been laid on the need of differentiating between them in order to avoid certain confusions. The difference has been expressed most clearly by Bergson, who, however, has only revived and elaborated the distinction drawn already by Spinoza (see LXXII in A Wolf, *The Correspondence of Spinoza*, p. 119). Time is commonly conceived abstractly and is thought of as composed of discrete instants or moments which follow one another in a uniform manner. For the purposes of science such an abstraction is often necessary. But *real time*, time as it actually passes, as it is actually experienced and lived in the world of changing events is not composed of such instants which replace one another. It is duration, that is a continuous change in which "the past gnaws into the future and swells as it advances" (H. Bergson, *Creative*

Evolution, p. 5). When time is conceived as a succession of discrete parts it is incomprehensible how any period of time, say an hour, can ever elapse, seeing that it involves the sequence of an infinity of parts. Hence Zeno's paradox of Achilles and the tortoise. But real time is only apprehended in intuition, and is continuous duration. The abstract concept of time, as commonly used in science, is the result of an attempt to assimilate it to space, or at least to measure it by means of certain correlated positions in space. Such is the view of Bergson, whose views may be summarized as follows. When science speaks of time it really refers to the motion of a body M on its trajectory. This motion is taken to represent time, and, by definition, is assumed to be uniform. Let M_1, M_2, M_3 be points which divide the path of the moving body, M, into equal parts from its starting point M₀ onwards. Then it will be said that 1, 2, 3, units of time have elapsed when M is at M_1, M_2, M_3 . Hence to consider the state of the universe at a certain time, say t , is simply to consider its state when M will be at the position Mt. No attention is paid to the actual flow of time, much less to its effect, on consciousness. For only points or positions are taken into account. And all that is considered in connection with all other parts of the universe is their positions on their several paths. With each *virtual position* of M (M_1, M_2, M_3 , ...) there is correlated a *virtual position* of all other moving bodies. But these correspondences in position are *simultaneous* which take no account of the flow of time, the continuous transitions from position to position in unbroken sequence. If real time could be measured by feeling, independently of physical events, then the sequence of physical events would continue to be expressed by the same equations, however much their actual tempo might be varied as judged independently by our duration-feeling. Science, as a matter of fact, has no symbols to express real succession or duration. See H. Bergson, *Time and Free Will* (1910), see also the article SPACE-TIME. (A Wo.)

DURAZZO (DURRES), a seaport of Albania. Pop. (1930) 8,739, of whom 70% were Mohammedans, 25% Orthodox, and 5% Roman Catholics. Most of the merchant class are of Vlachs origin. Durazzo is the seat of a Roman Catholic archbishop and a Greek metropolitan. It is built on the slope of Mt. Durazzo and stretches down into a picturesque valley, but is surrounded by marshes, dotted with lakes, and the water supply, from wells, is far from satisfactory. The old crenellated walls are dilapidated, plane trees grow on the gigantic runs of the old Byzantine citadel, and the harbour, commodious and safe when used by the Venetian galleys, is gradually becoming silted up, sandbanks rendering the approach difficult. The only features worthy of notice are the quay with its rows of cannon, and the viaduct, 750 ft. long, which crosses the marsh to the road to Tirana. The chief exports are olive oil, wheat, oats, barley, skins, tobacco, sumach and sheep. Salt is obtained by evaporation, and there are brick kilns in the district, while the making of the national costumes is an important industry.

Ep'damnus, the ancient name of Durazzo, was founded by a joint colony of Corcyreans and Corinthians towards the close of the 7th century B.C., and from its admirable position and the fertility of the surrounding country, soon rose into considerable importance, and played a part in bringing about the Peloponnesian War (431–404 B.C.). In 312 B.C. the city was seized by the Illyrian king Glaucias, and shortly after it passed to the Romans, who changed its name to Dyrrachum, and it again rose to importance. It was a favourite point of debarkation for the Roman armies, the great military road known as the Via Egnata led from Dyrrachum to Thessalonica (Salonica), and another highway passed southwards to Buthrotum and Ambracia. Broad swamps rendered the city almost impregnable, and in 48 B.C. Pompey made his last successful resistance to Caesar here. After the battle of Actium in 31 B.C. Augustus made over Dyrrachum to a colony of his veterans, it became a *civitas libera*, and reached the summit of its prosperity at the end of the 4th century when it was made the capital of Epirus Nova.

Its bishopric, created about A.D. 58, was raised to an archbishopric in 449. In 481 the city was besieged by Theodoric the

Goth, and during the 10th and 11th centuries was frequently attacked by the Bulgarians. In 1081 it was stormed by Robert Guiscard, the Norman, and in 1185 it fell into the hands of King William of Sicily, was surrendered to Venice in 1202, and in 1268 came into the possession of Charles of Anjou. In 1273 it was destroyed by an earthquake, but soon recovered from the disaster, and became an independent duchy under John of Anjou (1294-1304), and afterwards under Philip of Tarento. In 1333 it was annexed to Achaia, in 1336 to Serbia, and in 1394 to Venice. The Turks captured it in 1501, and held it till 1913. In that year Essad Pasha set up a government of his own in Durazzo, but in 1914 Prince William of Wied landed there as King of Albania, and Essad fled to Italy. His partisans, however, attacked the town, and three months later Prince William abandoned the country. At Kavajë, near Durazzo, an Albanian American school of agriculture was founded in 1925 for the promotion of better methods of cultivation and cattle raising.

Durazzo was a main point of disembarkation for the Italian troops invading Albania in 1939. During the Greek-Italian war of 1940-41 it was subjected to heavy air raids by the British. British warships also shelled the port from the Adriatic, disrupting Italian supplies to its armies facing the Greeks.

D'URBAN, SIR BENJAMIN (1777-1849), British general and colonial administrator, entered the British army in 1793. In 1794 he took part in operations in Holland and Westphalia. In 1795 he served under Sir Ralph Abercromby in San Domingo. He spent the years 1800-05 at the Royal Military college, and then served in Hanover under Lord Cathcart. In Nov. 1807 he went to Dublin as assistant-quartermaster general, being transferred successively to Limerick and the Curragh. He joined the army in the Peninsula in 1808 and acted as quartermaster general to General (afterwards Viscount) Beresford in the reorganization of the Portuguese army. He served throughout the Peninsular War, being present at Busaco, Albuera, Badajoz, Salamanca, Vittoria, the Pyrenees, the Nivelle, the Nive and Toulouse. He was made a K.C.B. in 1815. He remained in Portugal until 1816. In 1819 he became major general and in 1837 lieutenant general. From 1839 he was colonel of the 51st Foot.

Sir Benjamin began his career as colonial administrator in 1820 as governor of Antigua. In 1822 he was transferred to Demerara and Essequibo, then in a disturbed condition owing to a rising among the slaves consequent on the emancipation movement in Great Britain. In 1823 he carried out the amalgamation of Berbice with the other colonies, the whole forming the colony of British Guiana, of which D'Urban was first governor. The 10 years of his governorship in Cape Colony (1834-38) were of great importance in the history of South Africa. They witnessed the abolition of slavery, the establishment of the first legislative and municipal councils in Cape Colony, the first great Kafir war and the beginning of the Great Trek. The firmness and justice of his administration won the cordial support of the British and Dutch colonists. The eastern part of 1833 was occupied in founding an upriver mission on the eastern borders of the colony of Xhosa Kaffirs. To protect the inhabitants of the eastern province Sir Benjamin extended the boundary of the colony to the Kei river and erected military posts in the district, allowing the Xhosa to remain under British supervision. But Lord Glenelg, secretary for the colonies in the second Melbourne administration, adopted the view that the Kaffirs and their victims of systematic injustice. In a despatch dated Dec. 26, 1835, he instructed D'Urban to give up the newly annexed territories. At the same time Sir Andrew Stoddart, Bart. (1762-1864), was appointed lieutenant governor for the eastern provinces of the colony to carry out the policy of the home Government, in which the Kafir tribes were to be brought on terms of full equality with Europeans. One result of the new policy was to recreate a state of insecurity, bordering on anarchy, in the eastern province, and this condition was one of the causes of the Great Trek of the Dutch farmers which began in 1836. In various despatches D'Urban justified his position, characterizing the trek as due to "insecurity of life and property occasioned by the recent measures, inadequate compensation for the loss of the slaves, and despair of obtaining recompense for the

runous losses by the Kafir invasion." (See SOUTH AFRICA, UNION OF, and CAPE PROVINCE.) D'Urban was relieved of his office (May 1, 1837), but remained governor until the arrival of his successor, Sir George Napier, in Jan. 1838.

During his governorship Sir Benjamin helped the British settlers at Port Natal, who in 1835 named their town D'Urban (now written Durban) in his honour, but his suggestion that the district should be occupied as a British possession was vetoed by Lord Glenelg. D'Urban remained in South Africa until April 1846. In 1840 he was made a G.C.B., and in 1842 declined a high military appointment in India offered him by Sir Robert Peel. In Jan. 1847 he took up command of the troops in Canada, and held it at the time of his death at Montreal on May 25, 1849.

DURBAN, a seaport on the coast of Natal, Union of South Africa, situated in 29° 52' S., 31° 1' E., just south of the Umgeni river. It is 6,992 nautical miles from London by the West Coast route, and 7,785 via Suez. Owing to its low latitude and proximity to the Mozambique current, its climate is humid and sub-tropical. The mean annual temperature is about 70°, and the temperature ranges, both daily and annual, are comparatively small. The monthly means for July and January are 64.6° and 76.6°, the mean minimum for July being 52.3° and the mean maximum for January 84.5°. Rains mostly fall in the summer months, October to March inclusive, the annual rainfall is just over 40 inches. The dry season, however, is not so marked here as it is further inland, the six winter months receiving 29% of the total rainfall. The average number of rainy days is between 110 and 118. The relative humidity is high, making the climate rather enervating, a fact that is probably reflected by the large number of murricks, drawn by Zulus, which ply for hire in the streets. The health of the town is good, though malaria is liable to occur in the summer, and in 1926-27 there was a serious epidemic of dengue fever.

Durban is the largest urban centre in Natal, and is exceeded in the union only by Johannesburg and Capetown. In 1936 the population consisted of 95,033 Europeans (104,976 in 1941), 68,698 natives, 88,226 Asiatics and 7,649 "coloured" (mixed), making a total of 259,606. The town is built near the shores of a bay originally a shallow lagoon, 8 sq. mi. in extent, cut off from the sea by a line of ancient partially consolidated sand dunes. The northern end of this barrier, known as the Bluff, 195 ft. high, overlooks the narrow entrance to the lagoon. On the northern side of the entrance is a low sandy spit, called the Point. The main business part of the city is laid out on a low lying sandy tract on the north and northwestern side of the bay (i.e., the lagoon). In West Africa almost all of the principal shops, the theatre, and, at the western end, a large technical college, near which is a colossal statue of the late Louis Botha in the dress of a Boer general, erected by citizens of Durban. About the middle of West street is a rectangular area occupied by gardens and a large war memorial. Along the West street side of this open space is the general post office, while on the opposite, southern side, is a hotel and an imposing block of insurance offices. The western flank is occupied by shops, and on the eastern side is a block of buildings containing the town hall, municipal offices, public library and art gallery. The town hall has an assembly room, which is capable of accommodating 3,000 people, and which is fitted with a fine organ. The art gallery has some good pictures by modern British painters. The border of the lagoon is laid out as an esplanade, and is known as the Victoria embankment. It forms a picturesque walk, lined with palms. About the middle is an equestrian statue of Dick King, commemorating his famous nine days ride to Grahamstown (600 mi.) to obtain relief when Durban was besieged by the Boers in 1842.

The Harbour—The area about the Point is occupied by harbour works, loading sheds, etc. Here also is a memorial to Vasco da Gama. Owing to the presence of sandbanks it was originally difficult for any but smaller craft to enter the lagoon. The entrance has, however, been greatly improved. A wall has been constructed from the end of the Bluff for about 2,000 ft. out to sea. Nearly parallel with this the North pier was carried out to the same distance from the Point. The narrow entrance thus formed is kept

free from sand by the tidal scour and by dredging. The depth at LOW ST is about 37 ft., and the average rise of a spring tide is 4 ft. 11 inches.

Along the lagoon side of the Point are the sheds and wharves, of which there are about 3 mi. The depth alongside ranges from 23 to 34 ft. For coaling purposes electrically driven belt and bucket transporter appliances have been installed at the Bluff, capable of coaling five ships simultaneously. Oil depôts exist near by.

For repairs there is a floating dock capable of lifting 8,500 tons, and a patent slip capable of lifting craft up to 150 tons. At the southwestern end of the bay, near Congella, is a graving dock, 1,150 ft. long and 110 ft. broad. The depth of the entrance channel is 32 ft.

Not far away is the largest grain elevator in South Africa, with a storage capacity of 42,000 tons.

Extensive harbour developments, which expanded the capacity of the port, were completed during World War II. A large marine airport was opened in April 1940.

Homes and Recreation—Behind the business section rises a sharp ridge, the Berea, which runs in a more or less northerly direction until it meets the Umgeni river, where the Dwyka conglomerate, of which it is formed, is quarried for road metalling and harbour works. The Berea is the favourite residential quarter, and building sites are, therefore, dear. Most of the houses stand in their own grounds, surrounded by trees and shrubs, flowers and lawns. The streets are lined with the beautiful flamboyant tree, which is sharply restricted to the coastal strip of Natal. The general appearance of this quarter, and the views out to sea are very pleasing. A bridge was constructed across the mouth of the Umgeni.

On some of its other sides the town is hemmed in by a zone of Indian settlements, with squalid huts, untidy surroundings and sanitary conditions which could not be regarded as being satisfactory. On the sea front, north of the harbour, and stretching in the direction of the Umgeni, is a large esplanade, with its accompaniment of hotels, bathing conveniences, bandstands, etc. Near its northern end is a capacious concert hall, built in 1924. Between this and the river is an area of open beach and sand dunes. A part of the latter is occupied by the country club and its golf links and tennis courts. Durban is one of the most important seaside holiday resorts in South Africa. Many people from the high country inland come down during the winter for relaxation, and to escape the severe frosts. During July important race meetings are held here.

Public Services—The town is well supplied with public services. It has a good water supply, obtained from a large reservoir on the Umhlanga river, a water-borne sewage, electric light and a good tram service. The botanical gardens on the lower slopes of the Berea contain a fine collection of plants, more tropical in character than those in most other parts of South Africa. There are several other open spaces, such as Albert park, between West street and the bay, Mitchell park, Bulwer park, etc. Opportunities for sport are provided by a race course, near the centre of the town, polo and football grounds and golf links. Near the Port Natal University of South Africa.

Industry—The town is well supplied with public services. It has a good water supply, obtained from a large reservoir on the Umhlanga river, a water-borne sewage, electric light and a good tram service. The botanical gardens on the lower slopes of the Berea contain a fine collection of plants, more tropical in character than those in most other parts of South Africa. There are several other open spaces, such as Albert park, between West street and the bay, Mitchell park, Bulwer park, etc. Opportunities for sport are provided by a race course, near the centre of the town, polo and football grounds and golf links. Near the Port Natal University of South Africa.

exports are maize from the high veld, coal for bunking and export from the Natal coalfields, wattle bark from the midlands of Natal, and wool. It is also the chief focus of the sugar industry which occupies most of the coastal belt of Natal. Durban is second only to Capetown as a shipping centre in the union. In 1939, 1,699 vessels entered the harbour, with a total tonnage of 6,730,390, and in 1938-39, 6,566 passengers landed or embarked at Durban. The port played a very important part on the supply route to the middle east and India during World War II. Durban is also the centre of the whaling activities on this coast. The season lasts from May to November, and a whaling station has been established on the seaward side of the Bluff. The oil is used by local soap factories. The establishment of industries in the town is favoured by the plentiful supplies of coal, water, electricity and local labour that are available, and by the facilities for importing and exporting raw material and finished products. Land is being reclaimed at the southwestern end of the bay, and is quickly taken up for industrial development. Among the industries already established are those dealing with the production of soap, matches, jams and preserves, biscuits, furniture, etc.

See G. Russell, *History of Old Durban (to 1860)* (Durban, 1899), *Fifty Years of Municipal History*, compiled for the Corporation by the town clerk, 1904, *South Africa Year Book* (R. U. S. H. F.).

DURBAR, a term in India for a court or levee, from the Persian *darbar*. A *darbar* may be either a council for administering affairs of state, or a purely ceremonial gathering. In the former sense the native rulers of India in the past received visitors and conducted business in *darbar*. A *darbar* is the executive council of a native state. In the latter sense the word has come to be applied to great ceremonial gatherings like Lord Lytton's *darbar* for the proclamation of the queen empress in India in 1877, or the Delhi *darbar* of 1911.

DUREN, a town in Rhemish Prussia, Germany, on the right bank of the Roer, 19 mi. E. from Aix-la-Chapelle on the main line of railway to Cologne. Pop. (1939) 45,441. The Gothic St. Annakirche is said to contain a portion of the head of the saint, to the shrine of which frequent pilgrimages are made. There are several high grade schools, and in the town hall, a collection of antiquities. It is the seat of considerable manufactures, notably cloth, paper, flax spinning, carpet, artificial wool, sugar, beer and spirits, iron wares, needles, machinery, glass.

Duren derives its name from the *dura* or *duria*, assemblies held by the Carolingians in the 8th century. It received civic rights early in the 13th century. Hypothecated by the emperor Frederick II to Count William of Julich, it became incorporated with the duchy of that name, and with it passed to Prussia in 1816.

DURENE (1,2,4,5-tetramethylbenzene) $C_6H_2(CH_3)_4$, a hydrocarbon occurring in the light oils of coal tar and prepared by the action of methyl iodide on bromopropene or 4,6-dibromomethylbenzene in presence of sodium, or by the action of methyl chloride on toluene, in presence of anhydrous aluminum chloride. It crystallizes in plates, having a camphorlike smell, melting at $79-80^\circ C$ and it boils at $189-191^\circ C$.

DURER, ALBRECHT (1471-1528), German painter, engraver, and architect, was born at Nuremberg on May 21, 1471. He was the son of a goldsmith, Hans Durer, and his mother was Barbara. He was apprenticed to his father's trade, and settled soon after the middle of the 15th century in Nuremberg. He served as assistant under a goldsmith of the city, Hieronymus Holper, and in 1488 he married his master's daughter Barbara, the bridegroom being 16 and the bride 15 years of age. They had 13 children, of whom Albrecht was the second. Durer painted the portrait of his father (who died in 1502) twice, in 1490 and again in 1497. The works of these in the Uffizi at Florence, of the latter, four in the National Gallery, London (formerly in the Ashburnham Northampton collection) having the best claim to originality.

The young Albrecht was his father's favourite son, and was apprenticed at the age of fifteen and a half to the principal painter of the town, Michael Wolgemut. Wolgemut furnishes a complete type of the German painter of that age. There were

produced in the workshop of Wolgemut a great number of woodcuts for book illustration. We cannot with certainty identify any of these as being by the prentice hand of the young Dürer. Authentic drawings done by him in boyhood, however, exist, including one in silver point of his own likeness at the age of 13 in the Albertina at Vienna, and others of two or three years later in the print room at Berlin, at the British Museum and at Bremen.

At the end of his apprenticeship in 1490 he entered upon the usual course of travels—the *II. oder Jahre*—of a German youth. It had at one time been his father's intention to apprentice him to Martin Schongauer of Colmar. But after travelling two years in various parts of Germany, the young Dürer arrived at Colmar in 1492, only to find that Schongauer had died the previous year. He was received kindly by three brothers of the deceased master established there, and afterwards, still in 1492, by a fourth brother at Basle. Under them he evidently had some practice both in metal engraving and in furnishing designs for the woodcutter. There is in the museum at Basle a wood block of St. Jerome executed by him and elaborately signed on the back with his name. This was used in an edition of Jerome's letters printed in the same city in 1492. In the early part of 1494 he was working at Strasbourg, and returned to his home at Nuremberg immediately after Whitsuntide in that year. Of works certainly executed by him during his years of travel there are extant, besides the Basle wood-block, only a much injured portrait of himself, dated 1493 and originally painted on vellum but since transferred to canvas (this is the portrait of the Felix Goldschmid collection), a miniature painting on vellum at Vienna (a small figure of the Child Christ), and some half a dozen drawings, of which the most important are the characteristic pen portrait of himself at Erlangen, with a Holy Family on the reverse, much in the manner of Schongauer, another Holy Family in nearly the same style at Berlin, a study from the female nude in the Bonnat collection, a man and woman on horseback in Berlin, a man on horseback, and an executioner about to behead a young man, at the British Museum, etc. These drawings all show Dürer intent above all things on the sternly accurate delineation of ungeneralized individual forms by means of strongly accented outline and shadings curved, somewhat like the shadings of Martin Schongauer's engravings, so as to follow their modellings and roundness.

Within a few weeks of his return (July 7, 1494) Dürer was married, according to an arrangement apparently made between the parents during his absence, to Agnes Frey, the daughter of a well-to-do merchant of the city. By the autumn of the same year he must have made an excursion of some months to Italy. The evidences of this travel consist of (1) some fine drawings, three of them dated 1494 and others undated, but plainly of the same time, in which Dürer has copied, or rather boldly translated into his own Gothic and German style, two famous engravings by Mantegna, a number of the "Tarocchi" prints of single figures which pass erroneously under that master's name, and one by yet another minor master of the North-Italian school, with another drawing dated 1495 and plainly copied from a lost original by Antonio Pollaiuolo, and yet another of an infant Christ copied in 1495 from Lorenzo di Credi, (2) several landscape drawings done in the passes of Tirol and the Trentino, (3) two or three drawings of the costumes of Venetian courtesans, one of which is used in his great woodcut Apocalypse series of 1498, (4) a general preoccupation from this date with the problems of the female nude, treated in a manner for which Italy only could have set him the example, and (5) the clear implication contained in a letter written from Venice in 1506 that he had been there already 11 years before. Some time in 1495 Dürer must have returned from this first Italian journey to his home in Nuremberg, where he seems to have lived for the next ten years.

The hour when Dürer, the typical artist of the German nation, attained maturity was one of the most pregnant in the history of his race. It was the crisis, in northern Europe, of the transition between the middle ages and our own. The art of printing had been invented in good time to help and hasten the new movement of men's minds. Nor was it by the diffusion of written ideas only

that the new art supplied the means of popular enlightenment. Along with word printing, or indeed in advance of it, there had sprung into use another kind of printing, picture printing, or what is commonly called engraving. Just as books were the means of multiplying, cheapening and disseminating ideas, so engravings on copper or wood were the means of multiplying, cheapening and disseminating images which gave vividness to the ideas, or served, for those ignorant of letters, in their stead. The genius of Albrecht Dürer cannot be rightly estimated without taking into account the position which the arts of engraving on metal and on wood thus held in the culture of this time. He was indeed professionally and in the first place a painter, but throughout his career a great, and on the whole the most successful, part of his industry was devoted to drawing on the block for the woodcutter or engraving with his own hand on copper. Nuremberg was a favourable home for the growth and exercise of his powers. Of the free imperial cities of central Germany, none had a greater historic fame or a more settled and patriotic government. Nuremberg had imported before the close of the 15th century a fair share of the new learning of Italy, and numbered among her citizens distinguished humanists like Hartmann Schedel, Sebald Schreyer, Willibald Pirckheimer and Conrad Celtes. From associates like these Dürer could imbibe the spirit of Renaissance culture and research, but the external aspects and artistic traditions which surrounded him were purely Gothic, and he had to work out for himself the style and form language fit to express what was in him. During the first seven or eight years of his settled life in his native city from 1495, he betrays a conflict of artistic tendencies as well as no small sense of spiritual strain and strife. His finest work in this period was that which he provided for the woodcutter. After some half dozen miscellaneous single prints—"Samson and the Lion," the "Annunciation," the "Ten Thousand Martyrs," the "Knight and Men-at-arms," the "Men's Bath," etc.—he undertook, and by 1498 completed, his famous series of 15 great designs for the Apocalypse. Founding himself to some extent on traditional motives, Dürer conceived and carried out a set of designs in which the qualities of the German late Gothic style, its rugged strength and restless vehemence, its love of gnarled forms, writhing actions and agitated lines, are fused by the fire of the young master's spirit into vital combination with something of the majestic power and classic severity which he had seen and admired in the works of Mantegna. Of a little later date, and of almost as fine a quality, were the first seven of a large series of woodcuts known as the "Great Passion," and a little later again (probably after 1500), a series of 11 subjects of the Holy Family and of saints singly or in groups, then, towards 1504-05, came the first 17 of a set illustrating the life of the Virgin, neither these nor the "Great Passion" were published till several years later.

In copper engraving Dürer was at the same time diligently training himself to develop the methods practised by Martin Schongauer and earlier masters into one suitable for his own self-expression. He contented himself for the most part with Madonnas, single figures of scripture or of the saints, some nude mythologies founded upon the impressions received in Italy, and groups, sometimes bordering on the satirical, of humble folk and peasants. In the earliest of the Madonnas, the "Virgin with the Dragon fly" (1495-96), Dürer has thrown something of his own rugged energy into a design of the traditional Schongauer type. In examples of a few years later, like the "Virgin with the Monkey," the design of Mother and Child clearly betrays the influence of Italy and specifically of Lorenzo di Credi. On the other hand, he treats the subjects of the "Prodigal Son" and "St. Jerome in the Wilderness" in an almost purely northern spirit. In the nudes of the next four or five years, which included a "St. Sebastian," the so-called "Four Witches" (1497), the "Dream" or "Temptation," the "Rape of Anyonome" and the "Jealousy" or "Great Hercules," Venetian, Paduan and Florentine memories are found, in the treatment of the human form. In these early engravings the highly wrought landscape backgrounds, whenever they occur, are generally the most satisfying feature. This feature reaches a climax of beauty and

elaboration in the large print of "St. Eustace and the Stag," while the figures and animals remain still somewhat cramped and immature. In the first three or four years of the 15th century we find Dürer in his graver work still contending with the problems of the nude, but now with added power, though by varying methods. Thus the "Nemesis," belonging probably to 1503, is a marvellously wrought piece of quite unflinching realism in the rendering of a common type of mate, muscular, unshapely German womanhood. The conception and attributes of the figure are taken, as has lately been recognized, from a description in the "Manto" of Politan, the goddess, to whose shoulders are appended a pair of huge wings, stands like Fortune on a revolving ball, holding the emblems of the cup and bridle, and below her feet is spread a rich landscape of hill and valley. In the "Adam and Eve" of 1504 we find Dürer treating the human form in an entirely opposite manner, constructing it, that is, on principles of abstract geometrical proportion. The Venetian painter etcher, Jacopo di Barbari, whom Dürer had already, it would seem, met in Venice in 1494-95, and by the example of whose engravings he had already been much influenced, came to settle for a while in Nuremberg in 1500. He was conversant to some extent with the new sciences of perspective, anatomy and proportion, which had been making their way for years past in Italy, and from him it is likely that Dürer received the impulse to similar studies and speculations. At any rate a whole series of extant drawings enables us to trace the German gradually working out his own ideas of a canon of human proportion in the composition of his famous engraving of "Adam and Eve" (1504), which at first, as a drawing in the British Museum proves, had been intended to be an Apollo and Diana conceived on lines somewhat similar to one of Barbari's. Two or three other technical masterpieces of the engraver's art, the "Coat-of-Arms with the Skull," the "Nativity," with its exquisite background of ruined buildings, the "Little Horse" and the "Great Horse," belong to 1505.

The pictures of this earlier Nuremberg period are not many in number and not very admirable. Among the earliest seem to be two examples of a method practised in Italy especially by the school of Mantegna, but almost without precedent in Germany, that of tempera painting on linen. One of these is the portrait of Frederick the Wise of Saxony, formerly in the Hamilton collection and now at Berlin, the second, much disfigured by restoration, is the Dresden altar piece with a Madonna and Child in the middle and St. Anthony and St. Sebastian in the wings. A mythology reminiscent of Italy is the "Hercules and the Stymphalian Birds" in the Germanic museum at Nuremberg, founded directly upon the "Hercules and Centaur Nessus" of Pollaiuolo, now at New Haven, Conn., U.S.A. Of portraits, besides that of his father already mentioned as done in 1497, there is his own of 1498 at Madrid. Two totally dissimilar portraits of young women, both existing in duplicate examples, for each of which has been claimed the name Furlengerin, that is, a member of the Furlerger family at Nuremberg, belong to nearly the same time. Other panel portraits of the period are three small ones of members of the Tucher family at Weimar and Cassel, and the striking, restlessly elaborated half-length of Oswald Krel at Munich. In some devotional pictures of the time Dürer seems to have been much helped by pupils, as in the two different compositions of the Maries weeping over the body of Christ preserved respectively at Munich and Nuremberg. Two examples of high value are the Paumgartner altar piece at Munich, with its romantically attractive composition of the Nativity with angels and donors in the central panel and the fine armed figures of St. George and St. Eustace on the wings, and the "Adoration of the Magi" in the Uffizi at Florence.

In the autumn of 1505 Dürer journeyed for a second time to Venice, and stayed there until the spring of 1507. One of the motives for this journey was the prospect of a commission for an important picture from the German community settled at Venice, who had caused an exchange and warehouse—the *Fondaco de' Tedeschi*—to be built on the Grand canal, and who were then desirous of dedicating a picture in the church of St. Bartholomew. The picture painted by Dürer on this commission

was the "Adoration of the Virgin," better known as the "Teast of Rose Garlands"; it was subsequently acquired by the emperor Rudolf II., and carried as a thing beyond price upon men's shoulders to Vienna, it now exists in a greatly injured state in the State museum in Prague. Of all Dürer's works, it is the one in which he most deliberately rivaled the combined splendour and playfulness of certain phases of Italian art. A similar festal intention in design and colouring, with similar mastery in passages and even less sense of harmonious relations in the whole, is apparent in a second important picture painted by Dürer at Venice, "The Virgin and Child with the Goldfinch," formerly in the collection of Lord Lothian and now at Berlin. A "Christ disputing with the Doctors" of the same period, in the Barberini gallery at Rome, is recorded to have cost the painter only five days' labour. The most satisfying of Dürer's paintings done in Venice are the admirable portrait of a young man at Hampton Court (the same sitter reappears in the "Teast of Rose Garlands"), and two small pieces, one the head of a brown Italian girl modelled and painted with real breadth and simplicity formerly in the collection of Mr. Reginald Cholmondeley and now at Berlin, and the small and very striking little "Christ Crucified" with the figure relieved against the night sky, which is preserved in the Dresden gallery and has served as model and inspiration to numberless later treatments of the theme. An interesting, rather fantastic, portrait of a blonde girl wearing a wide cap, now in the Berlin museum, is dated 1507 and may have been done in the early months of that year at Venice. A portrait of a Venetian woman, discovered in 1914 at Vienna, belongs to this period, and possibly also the famous portrait of himself at Munich bearing a false signature and date, 1500. In the latter the artist modified his own lineaments according to a preconceived scheme of facial proportion, so that it must be taken as an ideal rather than a literal presentment of him.

From the spring of 1507 until the summer of 1520, Dürer was again a settled resident in his native town. Except the brilliant existences of Raphael at Rome and of Rubens at Antwerp and Madrid, the annals of art present the spectacle of few more honoured or more fortunate careers. His reputation had spread all over Europe. He was on terms of friendship or friendly communication with all the first masters of the age, and Raphael held himself honoured in exchanging drawings with Dürer. In his own country, all orders of men, from the emperor Maximilian down, delighted to honour him, and he was the familiar companion of chosen spirits among the statesmen, humanists and reformers of the new age. His temper and life seem to have been remarkably free from all that was jarring, jealous and fretful, unless, indeed, we are to accept as true the account of his wife's character which represents her as an incorrigible shrew and skinflint. The name of Agnes Dürer was for centuries used to point a moral, and among the unworthy wives of great men the wife of Dürer became almost as notorious as the wife of Socrates. It is to be noted that neither in Dürer's early correspondence with his intimate friend, Willibald Pirckheimer, nor anywhere in his journals, does he use any expression of tenderness or affection for his wife, only speaking of her as his house-mate and of her help in the sale of his prints, etc. But it is far to remember in her defence that Pirckheimer, when he denounced her in the letter which forms the basis of these imputations, was old, gouty and peevish, and that the immediate occasion of his outbreak against his friend's widow was a fit of anger because she had not let him have a pair of antlers out of the property left by Dürer. After her husband's death Agnes Dürer behaved with generosity to his brothers.

The 13 or 14 years of Dürer's life between his return from Venice and his journey to the Netherlands (spring 1507-midsummer 1520) may be divided according to the classes of work with which he was principally occupied. The first five years, 1507-11, are pre-eminently the painting years of his life. In them he produced what have been accounted his four capital works in painting, besides several others of minor importance. The first is the "Adam and Eve" dated 1507, two versions of

which exist: one in Florence at the Pitti palace, the other, which is generally allowed to be the original at Myrdin. To 1508 belongs the life-sized "Virgin with the Ius," a piece remarkable for the fine romantic invention of its background, but plainly showing the hand of an assistant perhaps Hans Baldung, in its execution the best version in the National gallery, at London, an inferior one in the Rudolphinum at Prague. In 1508 Durer returned to a subject which he had already treated in an early woodcut, the "Massacre of the Ten Thousand Martyrs of Nicomedia." The picture, painted for the elector Frederick of Saxony, is now in the Imperial gallery at Vienna. In 1509 followed the "Assumption of the Virgin" with the Apostles gathered about her tomb, a rich altar-piece with figures of saints and portraits of the donor and his wife in the folding wings, executed by Jacob Heller, a merchant of Frankfurt, in 1509. This altar-piece was afterwards replaced at Frankfurt (all except the portraits of the donors, which remained behind) by a copy, while the original was transported to Munich, where it perished by fire in 1674. In 1511 was completed another famous painting, multitudinous in the number of its figures though of very moderate dimensions, the "Adoration of the Trinity by all the Saints" now at Vienna.

In the meantime Durer had added a few to the number of his line engravings and had completed the two woodcut series of the "Great Passion," begun about 1498-99, and the "Life of the Virgin." In 1511 these two works were brought out for the first time, and the Apocalypse series in a second edition, and for the next three years, 1511-14, engraving both on wood and copper, but especially the latter, took the first place among Durer's activities. Besides such fine single woodcuts as the "Mass of St. Gregory," the "St. Christopher," the "St. Jerome," and two Holy Families of 1511, Durer published in the same year the most numerous and popularly conceived of all his woodcut series, that known from the dimensions of its 37 subjects as the "Little Passion" on wood, and in the next year, 1512, a set of 15 small copper-engravings on the same theme, the "Little Passion" on copper. Both of these must represent the labour of several preceding years: one or two of the "Little Passion" plates, dating back as far as 1507, prove that this series at least had been as long as five years in his mind. In thus repeating over and over on wood and copper nearly the same incidents of the Passion, or again in rehandling them in yet another medium, as in the highly finished series of drawings known as the "Green Passion" in the Albertina at Vienna, Durer shows an inexhaustible variety of dramatic and graphic invention, and is never betrayed into repeating an identical action or motive.

In 1513 and 1514 appeared the three most famous of Durer's works in copper-engraving, "The Knight and Death" (or simply "The Knight," as he himself calls it, 1513), the "Melancholia" and the "St. Jerome in his Study" (both 1514). These are the masterpieces of the greatest mind which ever expressed itself in this form of art. The idea at the bottom of the "Knight and Death" seems to be a combination of the Christian knight of Erasmus's *Enchiridion militis Christiani* with the type, traditional in mediaeval imagery, of the pilgrim on his way through the world. The "Melancholia," numbered "1," as though intended to be the first of a series, with its brooding winged genius sitting defectively amidst a litter of scientific instruments and symbols, is hard to interpret in detail, but impossible not to recognize in general terms as an embodiment of the spirit of intellectual research (the student's "temperament" was supposed to be one with the melancholic), resting sadly from its labours in a mood of lassitude and defeat. Comparatively cheerful beside these two is the remaining subject of the student saint reading in his chamber, with his dog and domestic lion resting near him, and a marvellous play of varied surface and chequered light on the floor and ceiling of his apartment and on all the objects which it contains. Besides these three masterpieces of line-engraving, the same years, 1513-15, found Durer occupied with his most important experiments in etching, both in dry-point ("The Holy Family and Saints" and the "St. Jerome in the Wilderness") and with the acid bath. At the same time he was

more taken up than ever, as is proved by the contents of a sketchbook at Dresden, with mathematical and anatomical studies on the proportions and structure of the human frame. A quite different kind of study, that of the postures of wrestlers in action, is illustrated by a little-known series of drawings, still of the same period, at Vienna. Almost the only well authenticated painting of the time is a "Virgin and Child" in the Imperial museum at Vienna. The portraits of the emperors Charles the Great and Sigismund (1512), in their present state at any rate, can hardly be recognized as being by the master's hand. An interval of five years separates the Vienna "Madonna" from the two fine heads of the apostles Philip and James in the Uffizi at Florence, the pair of boys' heads printed in tempera on linen in the Bibliothèque Nationale at Paris, the "Madonna with the Pink" at Augsburg, and the portrait of Wolgemut at Munich all of 1516. Among engravings of the same time are three Madonnas, the apostles Thomas and Paul, a bagpiper and two peasants dancing, and three or four experiments in etching on plates of iron and zinc. In wood engraving his energies were almost entirely given to his share in the great decorative schemes commanded by the emperor Max in his own honour, namely, the Triumphal Gate and the Triumphal March or Procession. A third and smaller commemorative design, the Triumphal Car, originally designed to form part of the second but in the end issued separately, was entirely Durer's own work. A far more successful effort of his genius is to be found in the marginal decorations done by him in pen for the emperor's prayer-book. This unequalled treasure of German art and invention has been broken up, the part executed by Durer being preserved at Munich, the later sheets, which were decorated by other hands, having been transported to Besançon. Durer's designs, drawn with the pen in pale lilac, pink and green, show an inexhaustible richness of invention and an easy freedom and playfulness of hand beyond what could be surmised from the sternness of those studies which he made direct from life and nature.

All these undertakings for his imperial friend and patron ceased with the emperor's death in 1519. A portrait drawing by the master done at Augsburg a few months previously, one of his finest works, served him as the basis both of a commemorative picture and a woodcut. In line engravings we have four more Madonnas, two St. Christophers, one or two more peasant subjects, the well known St. Anthony with the view of Nuremberg in the background, and the smaller of the two portraits of the cardinal elector of Mainz, and in wood-engraving several fine heraldic pieces, including the arms of Nuremberg.

In the summer of 1520 he set out for the Netherlands, together with his wife and her maid, in order to be present at the coronation of the young emperor Charles V, and if possible to conciliate the good graces of the all-powerful regent, Margaret. He journeyed by the Rhine, Cologne, and thence by road to Antwerp, where he was handsomely received, and lived in whatever society was most distinguished, including that of Erasmus of Rotterdam. Besides his written notes, interesting traces of his travels exist in the shape of the scattered leaves of a sketchbook filled with delicate drawings in silver point, chiefly views of places and studies of portrait and costume. Several of his finest portrait-drawings in chalk or charcoal, including those of his brother artists Lucas Van Leyden and Bernard Van Orley, as well as one of two fine portrait paintings of men belong to the period of this journey. So does a magnificent drawing of a head of a nonagenarian with a flowing beard who sat to him at Antwerp, together with a picture from the same head in the character of St. Jerome, the drawing is now at Vienna, the picture at Lisbon. Besides going to Aachen for the coronation, he made excursions down the Rhine from Cologne to Nimwegen, and back overland by Hertogenbosch, to Brussels, to Bruges and Ghent, and to Zealand with the object of seeing a natural curiosity, a whale reported ashore. The diary contains a passionate outburst of sympathetic indignation at the supposed kidnapping of Luther by foul play on his return from the diet of Worms. Without being, properly speaking, a reformer, Durer in his art and his thoughts was the incarnation of those qualities

of the German character and conscience which resulted in the Reformation, and personally, with the fathers of the Reformation he lived in the warmest sympathy.

On July 12, 1527, Durer reached home again. Drawings of this and the immediately following years prove that on his return his mind was full of schemes for religious pictures. There exist fine drawings for a "Lamentation over the body of Christ," an "Adoration of the Kings," and a "March to Calvary," of the last named composition, besides the beautiful and elaborate pen and ink drawing at Florence, three still more highly wrought versions in green monochrome exist, whether any of them are certainly by the artist's own hand is matter of debate. But no religious paintings on the grand scale, corresponding to these drawings of 1521-24, were ever carried out. The artist allowed much of his time and thoughts to be absorbed in the preparation of his theoretical works on geometry and perspective, proportion and fortification. Like Leonardo, but with much less than Leonardo's genius for scientific speculation and divination, Durer was a confirmed reasoner and theorist on the laws of nature and natural appearances. The consequence was that in the last and ripest years of his life he produced as an artist comparatively little. In painting there is the famous portrait of Hieronymus Holzschuher at Berlin. This and the Antwerp head of Jerome are perhaps the most striking examples of Durer's power of forcing into subordination to a general impression such a multiplicity of insistent detail as would have smothered any weaker conception than his. To the same period belong a "Madonna and Child" at Florence, and finally, still in the year 1526, the two famous pinnels at Munich embodying the only one of the great religious conceptions of the master's later years which he lived to finish. These are the two pairs of saints, St. John with St. Peter in front and St. Paul with St. Mark in the background. The John and Paul are conceived and executed really in the great style, with a commanding nobility and force alike in the character of the heads, the attitudes, and the sweep of draperies, they represent the highest achievement of early German art in painting. In copper engraving Durer's work during the same years was confined entirely to portraits, those of the cardinal elector of Mainz ("The Great Cardinal"), Frederick the Wise, elector of Saxony, Willibald Pirckheimer, Melanchthon and Erasmus. To the tale of his woodcuts, besides a few illustrations to his book on measurements (that is, geometry and perspective), and on fortification, he added only one Holy Family and one portrait, that of his friend Eoban Hesse. Of his theoretical books he succeeded in getting only two finished and produced during his lifetime, that on geometry and perspective or measurements—to use his own title—which was published at Nuremberg in 1525, and that on fortification, published in 1527, the work on human proportions was brought out shortly after his death in 1528. His labours, whether artistic or theoretic, had for some time been carried on in the face of failing health. In the canals of the Low Countries he had caught a fever, of which he never shook off the effects. We have the evidence of this in his own written words, as well as in a sketch which he drew to indicate the seat of his suffering to some physician, and again in a portrait engraved on wood just after his death, from a drawing made no doubt not long before in this portrait we see his shoulders already bent, the features somewhat gaunt, the old pride of the abundant locks shorn away. The end came suddenly on the night of April 6, 1528. An appropriate *Requiescat* is contained in the words of Luther, in a letter written to their common friend Eoban Hesse—"As for Durer, assuredly affection bids us mourn for one who was the best of men, yet you may well hold him happy that he has made so good an end, and that Christ has taken him from the midst of this time of trouble and from greater troubles in store, lest he, that deserved to behold nothing but the best, should be compelled to behold the worst. Therefore may he rest in peace with his fathers Amen."

The principal extant paintings of Durer, with the places where they are to be found, have been mentioned above. Of his drawings, which for students are the most vitally interesting part of his works, the richest collections are in the Albertina at

Vienna, the Berlin museum and the British Museum. The Louvre also possesses some good examples, and many others are dispersed in various public collections, as in the Musée Bonnat at Bayonne, at Munich, Hamburg, Bremen, Frankfurt, Dresden, Basle, Milan, Florence and Oxford, as well as in private hands.

The principal editions of Durer's theoretical writings are: *Geometry and Perspective—Underweisung der Messung mit dem Zirckel und Richtschylt, in Linien, Eben und ganzen Corporen* (Nuremberg, 1525, 1533, 1538). A Latin translation of the same, with a long title (Paris, Wechel, 1532) and another ed. in 1535. Again in Latin, with the title *Institutionum geometricarum libri quatuor* (Arnhem, 1605).

Fortification—Eltliche Unterricht zu Befestigung der Stett, Schloss und Flecken (Nuremberg, 1527), and other editions in 1530, 1538 and 1563 (Arnhem). A Latin translation with the title *De urbis arcebus, castellisque munitis et condendis* (Paris, Wechel, 1537).

Human Proportion—Herrnerner und begriffen vuer Bucher vuer menschlicher Proportion (Nuremberg, 1528, and Arnhem, 1603). Latin translation *De symetria partium in rectis formis humanorum corporum libri in latinum conversi, de varietate figurarum, etc.* (Arnhem, 1528, 1533 and 1534), (Paris, 1535, 1537, 1557). German translation (Paris, 1557, Arnhem, 1613, 1614). Italian translation (Venice, 1501, 1594), Portuguese translation (1500), Dutch translation (Arnhem, 1621, 1662).

The private literary remains of Durer, his diary, letters, etc., were published most completely in Lange and Fubser's *Durers schriftlicher Nachlass* (Halle, 1903), W. M. Conway's *Literary Remains of A. Durer* (London, 1889) contains extensive transcripts from the mss in the British Museum.

The principal remaining literature on the subject will be found in the following books and treatises: F. Lippmann, *Zeichnungen von A. Durer in Nachbildungen* (1883-1905), A. Springer, *Albrecht Durer* (1892), D. Bueckhardt, *Durers Aufenthalt in Basel, 1494-95* (Munich, 1892), G. von Treyer, *A. Durers venezianischer Aufenthalt, 1494-95* (Strasbourg, 1892), S. R. Koehler, *A Chronological Catalogue of the Engravings, Dry Points and Etchings of A. Durer* (New York, 1894), L. Cust, *A. Durer, a Study of his Life and Works* (1897). Durer Society's Publications (1898-1907), edited by C. Dodgson and S. M. Peartrie, M. Thuesen, *Durer, die Geschichte seines Lebens* (2nd ed. 1884, English translation 1883), B. Haendcke, *Die Chronologie der Landschaften A. Durers* (Strasbourg, 1890), H. Wolff, *Die Kunst A. Durers* (Munich, 1905, 2nd ed. 1908), V. Scherer, *A. Durer (Klassiker der Kunst, IV)*, (3rd ed. 1908), Max Friedländer, *A. Durer* (1921), Pierre de Colombyer, *Albert Durer* (1927).

Singer's *Versuch einer Durer-Bibliographie* (Strasbourg, 1903), A. Jellinek's *Internationale Bibliographie der Kunstwissenschaft* (Berlin), an edition de luxe of Dr. Willm. Kurth's *Complete Woodcuts of Albrecht Durer* (Intro by Campbell Dodgson) was published in 1927.

DURESS, in law, constraint or compulsion. Duress may be of two kinds. It may consist of personal restraint or actual violence or imprisonment, or it may be by threats (*per minas*), as where a person is compelled to an act by threats of immediate death or grievous bodily harm (See COERCION, CONTRACT).

D'URFEY, THOMAS (1653-1723), better known as Tom D'Urfey, English song writer and dramatist, belonged to a Huguenot family settled at Exeter. Honoré d'Urfé, the author of *Astrée*, was his uncle. His first play, *The Siege of Memphus, or the Ambitious Queen*, a bombastic rhymed tragedy, was produced at the Theatre Royal in 1676. He was much more successful with his comedies, which had brisk, complicated plots carried out in lively dialogue. He had a light touch for fitting words on current topics to popular airs, moreover, many of his songs were set to music by his friends Dr. John Blow, Henry Purcell and Thomas Farmer. Many of these were introduced into his plays. Addison in the *Guardian* (No. 67) relates that he remembered to have seen Charles II. leaning on Tom D'Urfey's shoulder and humming a song with him. Even William III. liked to hear him sing his songs, and as a strong Tory he was sure of the favour of Princess Anne, who is said to have given Tom fifty guineas for a song on the Electress Sophia, the next heir in succession to the crown. "The crown's far too weighty, for shoulders of eighty," said d'Urfey, with an indirect compliment to the princess, "So Providence kept her away,—poor old Dowager Sophy." He was poor in his old age, but his gaily and invincible good humour had made him friends in the craft, and by the influence of Addison his *Fond Husband*, or *The Plotting Sisters* was revived for d'Urfey's benefit at Drury Lane on June 15, 1713. He died on Feb. 26, 1723.

Lord Grey at Edinburgh in Sept. 1834 Brougham made a venomous attack on Durham, repeated shortly afterwards at Salisbury, and anonymously in the *Edinburgh Review*. But the strength of Durham's position in the country was shown when a concourse of more than a hundred thousand persons assembled to hear him speak at Glasgow Green in October. Durham however found no place in the Melbourne administration, partly because of his difficult temper, and partly on account of his radicalism.

In 1837 Durham accepted the post of governor general and lord high commissioner in Canada, with the almost dictatorial powers conferred on him by an act passed in Feb. 1838, by which the constitution of Lower Canada was suspended for two years. Having secured the services of Charles Buller (q.v.) as first secretary, and having appointed Thomas Turton and Edward Gibbon Wakefield (q.v.) to be his unofficial assistants, Durham arrived at Quebec on May 28, 1838. Papineau's rebellion had been quelled, but the French Canadians were sullen, the attitude of the United States equivocal, and the general situation dangerous, especially in the Lower Province where government was practically in abeyance. Durham at once issued a conciliatory proclamation. He dismissed his predecessor's executive council and created a new and unprejudiced one. On June 28, the day of Queen Victoria's coronation, he issued a proclamation of amnesty, from which eight persons only were excepted, these were to be transferred from Montreal to Bermuda, where they were to be imprisoned without trial. Papineau and 15 other fugitives were forbidden on pain of death to return to Canada.

These proceedings were violently attacked in England by Brougham. Of the ministers Lord John Russell alone defended the public servant to whom they had promised "the most unflinching support", and the prime minister and the colonial secretary, who had signified their "entire approval," now disavowed the ordinance, and earned an Act of Indemnity the terms of which were insulting to Durham. The latter immediately resigned, but before returning to England he put himself in the wrong by attempting a public justification of his actions. He laid his memorable "Report on the Affairs of British North America," before parliament on Jan. 31, 1839. This report, one of the greatest state papers in the English language, laid down the principles, then unrecognized, which have guided British colonial policy ever since. It was not written or composed by Charles Buller, as Brougham was the first to suggest, and the credit for the statesmanship it exhibits is Lord Durham's alone, though he warmly acknowledged the assistance he had derived from Buller, Wakefield and others in preparing the materials on which it was based. With regard to the future government of British North America, Durham had at first inclined towards a federation of all the colonies on that continent, but as a more immediately practical policy he advised the legislative union of Upper and Lower Canada. He further urged the creation of an executive council responsible to the colonial legislature, he advised state aided emigration on the broadest possible scale, and the formation of an intercolonial railway for the development of the whole country. Meantime Durham, who almost alone among the statesmen of his time saw the importance of imperial expansion, interested himself in the emigration schemes of Gibbon Wakefield (q.v.), he became chairman of the New Zealand Company, and was thus concerned in the enterprise which forestalled France in asserting sovereignty over the islands of New Zealand in Sept. 1839. He died at Cowes on July 28, 1840, just five days after the royal assent had been given to the bill giving effect to his project for uniting Upper and Lower Canada.

Lord Durham filled a larger place in the eyes of his contemporaries than many statesmen who have been better remembered. He was in his lifetime regarded as a great popular leader, and his accession to supreme political power was for some years considered probable by many, his opinions were, however, too extreme to command the confidence of any considerable party in parliament before 1840. That Brougham hated him and Melbourne feared him, is a tribute to his abilities, and in the first Reform Act, of which he was the chief author, and in the famous *Report* on the principles of colonial policy, he left an indelible mark on

English history. His personal defects of character did much to mar the success of a career, which, it must be remembered, terminated at the age of 48. He was impatient, hot-tempered, hypersensitive to criticism, vain and prone to take offence at fancied slights, but he was also generous and unvindictive, and while personally ambitious his care for the public interest was genuine and untiring.

By his first wife Durham had three daughters, by his second, who was a lady of the bedchamber to Queen Victoria but resigned on her husband's return from Canada, he had two sons and three daughters, the eldest son, Charles William, the "Master Lambton" of Sir Thomas Lawrence's celebrated picture, died in 1831, the second, George Frederick d'Arcy (1828-1879), succeeded his father as 2nd earl of Durham. The latter's son, John George Lambton (1855-1928), became 3rd earl in 1879.

Reid, *Life and Letters of the First Earl of Durham* (10 vols., 1906). *The Grenville Memoirs*, parts I and II (1874-87), Richard, duke of Buckingham and Chandos, *Memoirs of the Courts and Cabinets of William IV and Victoria* (2 vols., 1861), William Harris, *History of the Radical Party in Parliament* (1885), Harriet Martineau, *History of the Thirty Years Peace* (4 vols., 1877), William Kingsford, *History of Canada*, vol. x (10 vols., Toronto, 1887-98), H. E. Egerton, *Short History of British Colonial Policy* (1897).

DURHAM, a county of England bounded north by Northumberland, east by the North sea, south by Yorkshire, and west by Westmorland and Cumberland. Area 1,014.7 sq. mi. The Derwent, a tributary of the Tyne, forms part of the northern boundary with Northumberland, while the Tees in the south forms almost the whole of the boundary with Westmorland and Yorkshire. The county is divided into a highland west and a lowland east. No clearly marked contour separates these regions but geologically the Permian scarp, forming the right bank of the middle Wear and continuing north-north-eastwards to just south of Tynemouth is a suitable dividing line. West of this the Carboniferous limestone series prevails, a succession of thick beds of limestone with intervening sandstones and shales. This series forms the high ground of the north Pennines which are the backbone of the western section of the county. It is, however, broken by intrusive dykes and sills of basalt, especially in the Tees valley above Middleton, one of these, the Great Whin Sill, extends 20 miles. The Cockfield dyke and Little Whin Sill are similar intrusions of basalt. Millstone Grit caps many of the higher points in the west as at Muggleswick and Walsingham commons. On these plateaux, Bolis Law reaches 1,778 ft. and Fotherly hill 1,504 feet. The outcrop of the Millstone Grit broadens eastward until it is covered by the Durham coalfield which occupies the centre of the county from Newcastle and South Shields to Barnard Castle. There are some small Silurian outcrops near Cronkley on the Tees, once famous for its slate pencils. South and east of the Permian Scarp the newer rocks are exposed and dip eastwards or south eastwards. The Permian magnesian limestone reaches from the Tees to South Shields in a broad tract and occupies the coast between that town and Hartlepool. The south-eastern corner of the county is low lying with Triassic and Jurassic material—red marls and sandstones with beds of gypsum and rock salt.

The drainage system as represented by the major streams, the Wear, Derwent and Tees, bears a curious relation to the geology. When flowing over the older rock of the west they follow a general north west to south-east line, well marked in the Upper Wear and Tees, but, once they enter the newer rocks, the general direction of the drainage runs almost at right angles south west to north east. Of additional interest is the final section of the Wear from Chester le Street to the sea. In pre-glacial times the south west to north section of the middle course continued and the Wear was a tributary of the Tyne entering it just to the west of Gateshead. The blocking of its former lower course by glacial debris caused it to turn at Chester-le-Street to the eastward and it cut through the low Permian scarp and found the sea at its present mouth at Sunderland. Between the Wear and lower Tees is the strange valley of the Skerne. This river flows on Permian rock in an

opposite direction to the general trend of the larger rivers and enters the Tees just as it changes its course (near Darlington) from the upper north-west to south-east section on the older rocks (where it takes advantage of important fault lines) to its lower course on newer rocks in a broad open valley with wide stretches of sand near the coast.

Glacial deposits containing derived material from the Cheviots and Pennines obscure the older rocks. There are evidences from sunk meanders in the middle courses of the Wear and Tees, raised beaches, and submerged forests off the coast at West Hartlepool and other points of post-glacial earth movements. Except in the western moorlands only a few scraps of the county have been left in their natural state. The ballast hills at Shields, Jarrow and Hartlepool, have many foreign plants elsewhere unknown in England. Stockton was almost the last retreat in England of the native black rat. Peatbog remains testify to the former abundance of deer, wild ox and boar, which appear to have existed in the reign of Henry VIII, records of red deer are found in the 18th century.

Early Settlement—Evidence of early man is scarce. It would seem that the area was but sparsely populated at least until Saxon times. Copt hill, Houghton-le-Spring, has a barrow which shows a series of burials, the earliest of which may be of neolithic date. Finds of the Bronze age are more numerous, yet from their characteristic distribution along the river valleys, especially those of the Tyne and Wear, it may be taken that the Bronze age in vaders were more "birds of passage" than settlers. The Bronze hoard at Heathery Burn Cave has yielded important finds. Evidence of the Iron age is very scanty—a fine late Iron age sword, at Barnston, near Sadberge being its only representative.

History—In Roman and Romano British times, county Durham was an outpost and the main concern of the Romans was for the safety of communication to the frontier walls. Through the county ran the great north road, from outside York via Cataractum to Vindua at the bend of the Wear and thence northward to the Tyne at Constopitum. Chester-le-Street and South Shields were Roman stations. The post-Roman centuries saw the county overrun by northern raiders until the Saxon settlement and the establishment of the kingdom of Northumbria. The church sits at Monk Wearmouth (Sunderland), Jarrow, Easington, near Bishop Auckland, and numerous sculptured crosses (as those at Aycliffe) are of the Anglo-Saxon period.

In the 6th century Northumbria was divided into Bernicia and Deira, separated by the Tees, the latter including the district afterwards known as Durham. The post-Norman palatinate grew around a grant of land originally made by Egfrith to St. Cuthbert on his election to the see of Lindisfarne in 685. On the transference of the see to Chester-le-Street in the 9th century, Guthred the Dane endowed it with the whole district between the Tyne and the Wear, stretching west as far as Watling street, a grant confirmed by Alfred, the endowment was again enriched at the establishment of the see at Durham in 995. The ravages of the Danes caused much disruption in this area in the 9th century when the Tees formed the northern boundary of the Danelaw. Durham continued, however, to form part of the earldom of Northumbria, and it was not until after the purchase of the earldom by Bishop Walcher in 1075 that the bishops began to exercise regal rights in their territory. The term palatinate is applied to the bishop in 1293. At the time of the Conquest the bishop's possessions included nearly all the district between the Tees and the Tyne, except Sadberge, and also the outlying districts of Bedlingtonshire, Northamshire, Islandshire and Crayke, together with Hexhamshire, the city of Carlisle, and part of Teviotdale. Henry I deprived the bishopric of the last three but made over to it three villas of the earldom of Northumberland. The wapen take of Sadberge was purchased by Bishop Pudsey in 1189, but continued independent in administration. The division into the four wards of Chester-le-Street, Darlington, Easington and Stockton existed in the 13th century. The diocese was divided into the archdeaconries of Durham and Northumberland.

The palatinate was administered by a steward with a sheriff, coroners, chamberlain and chancellor. The palatine assembly

represented the whole county and dealt chiefly with fiscal questions. The bishop's council, consisting of the clergy, the sheriff and the barons, regulated judicial affairs. The prior of Durham had his own court. The repeated efforts of the crown to check the powers of the palatinate bishops culminated in 1536 in the Act of Resumption, which deprived the bishop of much of his judicial power. In 1596 further restrictions were imposed and in 1646 the palatinate was abolished. It was revived, however, after the Restoration, and continued with much the same power until the Act of 1836, which finally vested the palatine jurisdiction in the crown. The most important palatinate barons of the 12th century were the Hiltons, the Bulmers, the Conyers, the Hansards and the Lumleys. The Nevilles owned large estates in the county, which they ruled from Raby castle. Owing to its isolated position the palatinate took little part in the great rebellions of the Norman and Plantagenet period. On the outbreak of the Civil War Durham inclined to support the cause of parliament, and in 1640 harboured the Scottish army. In 1642 the earl of Newcastle organized the western counties for the king, but in 1644 the palatinate was again overrun by the Scottish army, and after Marston Moor fell entirely into the hands of the parliament.

Agriculture—Agriculture centres in the river valleys. East of the line from Barnard Castle to Consett the hills are covered with a dry loam, whose fertility varies with its depth. West of the line the hills are in great part waste moorland. About 58½% of the total area of 645,739 ac. was under cultivation in 1939 and of this two thirds was in permanent pasture, including 132,482 ac. of rough pasture. Oats, with 33,854 ac. were the main crop, with wheat (20,652 ac.) and barley (5,797 ac.) coming next. Potatoes and turnips and swedes, with 24,156 ac. almost equally divided, were prominent among the green crops. Cattle are imported. The sheep are esteemed, particularly the Teesdale and Wensdale breeds. The National Trust owned only 18½ ac. in Durham in 1942.

Industrial Activities—The coal-field has two sections, that west of Durham on the Pennine plateau where early mining occurred, and that east of the Wear. In the former region the coal measures outcrop on the valley sides and the mines are shallow. In the latter the coal is beneath the Permian rocks and the mines deep but productive. Little mining is done now west of Durham as the mines are shallow and the habitations consequently scattered, but east of the Wear large quantities of coal are raised, which can easily be transported to the coast for exportation. Here the big industrial towns are gathered. The Frosterley marble has been quarried for many centuries near Stanhope, and excellent slate is quarried at several places. Fire-clay is obtained in various parts of Durham, and exported in considerable quantity. The industrial districts may be taken to be almost wholly east of a line from Darlington through Bishop Auckland to Consett. The manufacture of machines, appliances, locomotives, trams and tools is important, and the ship-building yards on the Tyne are second only to those on the Clyde, building is carried on also at Sunderland, the Hartlepool's and Stockton-on-Tees. The use of the waste gases from the iron foundries gives an impetus to the manufacture of chemicals, glass and bottles and earthenware. The heavy chemical industry has developed on Tees-side. Local iron ore was formerly used, but now vast quantities are imported. The Tyne and the Tees mouth are the main areas. Much timber is imported from Scandinavia. There is a large production of salt gypsum and a tidal manures on the Tees mouth. The sea fisheries of Sunderland and Hartlepool are valuable.

The decline in shipping and the contraction of foreign markets (especially for coal), combined with the cessation of intensive wartime activity, led to widespread unemployment and poverty in the industrial region and Tyne-side in the decades between World Wars I and II. Unemployment in June 1931 reached a peak of about 34% of the insured population, and relief from public funds was annually more than double the amount per capita expended in the country as a whole. Complete recovery from this condition was almost impossible and was made the more difficult by the deteriorated financial position of the local industries and the water-logged condition of many mines in the southwest of the county. When, therefore, under the 1st of 1934 almost all Durham became a "special area," the commissioner's attention was primarily directed toward the attraction of new industries to the area. A development board for the northeast as a whole was formed, along with local development councils. Derelict sites were cleared, public works were undertaken by the local authorities with the aid of government grants and a trading estate of 700 ac. was established in 1936 at Gateshead, within two m. of Newcastle, for light industries, while facilities were created to provide capital to potentially successful small businesses. In addition, land settlement schemes were promoted. The success of these measures led to an expansion of the commissioner's powers under the 1937 act, so that further sites were cleared and new factories set up outside trading estate areas.

The I.N.E.R. main line runs northward through Darlington, Dur-

ham and Gateshead, and there are branches through the mining and industrial districts. The company also owns some docks. From Stockton to Darlington the railway, engineered by George Stephenson and opened in 1825. Its main object was to transport coal to the coast for exportation.

Administration and Population.—The area of the administrative county is 973.7 sq. mi., with a population (est. 1938) of 884,000. Wartime movements, caused mainly by evacuation, led to a decline of 6% in the county population between Sept. 1939 and Feb. 1941. The county boroughs are Darlington, Gateshead, South Shields, Sunderland and West Hartlepool. Municipal boroughs are the city of Durham, Hartlepool, Jarrow and Stockton-on-Tees. There are 11 urban districts. Durham is in the northeastern circuit, and sessions are held at Durham. There are two courts of quarter sessions and the county is divided into 25 petty sessional divisions. It is in the diocese of Durham, excepting part of one parish in that of York, and contains 168 civil parishes. The bishop strongly opposed in 1614 a bill for securing representation to the county and city of Durham and the borough of Barmston Castle. The county was first summoned to return members to parliament in 1554. After 1918 it returned one member for each of 11 divisions. The five county boroughs and Stockton-on-Tees also return one member each, except Sunderland, which returns two.

DURHAM, a city, and county town of Durham, England, in the Durham parliamentary division, 256 mi. NW from London, on the LNER Pop. (est. 1938) 19,370. Area 6.3 sq. mi. The nucleus of the site is a narrow, rocky peninsula formed by a sharp bend of the river Wear, on which stands the cathedral and castle. Though the mediaeval city grew around this site there are indications of earlier settlement, particularly on Maiden hill, where there is a Romano-British encampment. On the projecting rock rising some 70 ft. above the river the monks of Lindisfarne found, in 995, a resting place for the body of St. Cuthbert, which they had removed from its tomb in fear of Viking raids. The naturally strong position selected was possibly artificially fortified also, thereby laying the foundations of one of the few examples in Britain of a mediaeval fortress city. In 1928 it was reported that Durham castle was in danger of collapse from moving foundations. A national appeal for £150,000 "to save the castle from falling into the river" was made, and the restoration was successfully completed.

On the peninsula, which was called Dunholm (softened in Norman times to Duresme, whence Durham), a church was built by Bishop Ealdhun and the see was removed thither from Chester-le-Street in 995. In 1093 Ealdhun's church was rebuilt by Bishop Saint Calais, who changed the early establishment into a Benedictine abbey. The grand Norman building in which his designs were carried out remains, with numerous additions. The cathedral library, formerly the dormitory and refectory of the abbey, contains a number of printed books and MSS. and the relics found in St. Cuthbert's grave.

In 1072 Earl Waltheof erected the castle to the north of the cathedral, but Ranulph Flambard was the designer of the Norman fortifications as they can be traced today. Of this there remains a beautiful crypt chapel. Other interesting portions are the Norman gallery, with its fine arcade, Bishop Hatfield's Hall of c. 1350, a reconstruction of the previous Norman one by Bishop Pudsey, and the Black Staircase of fine woodwork of the 17th century.

The church of St. Mary le Bow in the North Bailey is a 17th century building on a very ancient site, while that of St. Mary the Less possesses slight traces of Norman work. Of other churches in Durham, the site of St. Oswald is apparently pre-Norman, and the building contains Norman work of Bishop Pudsey, also some fine early 15th century woodwork. St. Mar-

gret's and St. Giles's churches show work of the same period while the latter has earlier portions.

The remarkable meander of the Wear served as a natural defense and replaced, in parts, the usual mediaeval town wall. Three of the present bridges across the river are old, that of Elvet having been built 1153-95. Framwellgate was rebuilt in the early 13th century. Outside the city on the Wear is the priory of Finchale (1106), of which there are considerable remains of Early English and later styles, but in the main decorated. The earliest charter, dated 1179 or 1180, is a grant of exemption from toll market and hearth. Before that time, however, the monks had a little borough at Elvet, which is divided from Durham by the Wear and afterward became part of the city. In 1183 the city was at farm and rendered 60 marks. The bishop of Durham, among other privileges, claimed a mint in the city, which record in Boldon Book rendered ten marks yearly until its value was reduced by that established by Henry II at Newcastle, and it was temporarily abolished by the same king.

The palatinate of Durham in the middle ages was a great border ecclesiastical state occupying the extent of the present county, with many outlying portions, and the cathedral functioned as "half church of God, half castle against the Scots." In the neighbourhood of the city is Neville's Cross, of which little remains. A battle was fought there in 1346 resulting in the defeat of the Scots. With the Reformation came the rise of other city buildings. A grammar school was founded by Henry VIII in place of the monastic school. The town hall, a 16th century building, was reconstructed in 1851. The city possesses a guild hall and shire hall together with other county buildings. Four miles west of the city is the great Roman Catholic college of St. Cuthbert, Ushaw, the representative of the old college at Douai.

Durham was at first governed by a bailiff appointed by the bishop, but in 1505 Bishop Pilkington ordained that the government should consist, in addition to the bailiff, of one alderman and twelve assistants, the latter to continue in office for life and the former to be chosen every year from among their number. This form of government was replaced in 1602, under the charter of Bishop Matthew, by that of a mayor, 12 aldermen and 24 burgesses, the aldermen and burgesses forming a common council and electing a mayor every year from among the aldermen. This was confirmed by James I, but in 1684 the corporation were obliged to resign their charters to Bishop Crew, who granted them a new one, probably reserving to himself a right of veto on the election of the mayor and aldermen. At the time of the Revolution, however, Bishop Matthew's charter was revived and continued to be the governing charter of the city until 1770, when, owing to dissensions as to the election of the common council, the number of aldermen was reduced to four and the charter became void. No mayor or aldermen were elected for 10 years, but in 1780 Bishop Egerton, on the petition of the burgesses, granted them a new charter, which was practically a confirmation of that of 1602 and remained in force until the Municipal Reform act of 1835. Being within the county palatine, the city of Durham sent no members to parliament, until, after several attempts beginning in 1614, it was enabled by an act of 1673 to return two members, which it did until 1885, when the number was reduced to one. It was disfranchised in 1918.

The University.—Prior Richard de Holon (1200-1308) erected a hall in Oxford for students from Durham. In 1380 Bishop Hatfield refounded this hall as Durham college, which became Trinity college (see OXFORD) on a new foundation (1555). Henry VIII had the unfulfilled intention of founding a college in Durham, and a similar attempt failed during the Commonwealth. In 1831 the scheme for a college was projected by the chapter, an act of 1832 specified the foundation as a university, which was opened in 1833. In 1837 the university received its charter from William IV. Instruction in civil engineering and mining was established as early as 1837. In 1871 the university and the North of England Institute of Mining and Mechanical Engineers co-operated to found a college at Newcastle-upon-Tyne, which was incorporated with the university in 1874. The College of Medicine at Newcastle has been connected with Dur-

ham university since 1852. In 1895 women were admitted to degrees. In 1889 music degrees were instituted, and a professorship was founded in 1897.

In 1908 the university was reconstituted to consist of the Durham and the Newcastle divisions. The latter had the college of medicine and Armstrong college, while the Durham colleges, University college, Hatfield college, St Chad's college, St John's college, St Mary's college (women) and three residential colleges are controlled by the former. The university was later reorganized along lines suggested by a royal commission appointed in 1934, so that, although it still consisted of two divisions known as Durham colleges and King's college, Newcastle, the senate received greatly increased powers over the university as a whole.

Industries—The corporation of Durham claim their fair and market rights under Bishop Hugh de Puselet's charter of 1179, confirmed in 1565, as a weekly market and three yearly fairs. There is also a fourth fair. In 1610 the bishop recovered the markets and fairs, which he afterward leased to the corporation for a rent of £20 yearly until they were purchased from the ecclesiastical commissioners in 1860. Durham has never been noted for any particular trade, and the attempts to introduce the manufacture of cloth and wool in the 17th and 18th centuries were failures. The manufacture of carpets was begun in 1814.

The uplands have many collieries and ironworking and smelting is important. Durham is no longer one of the great cities of the north, but has become a small market town for the industrial population.

DURHAM, a city of North Carolina, U.S., 25 mi. W of Raleigh, the county seat of Durham county. It is on federal highways 15, 70, 264 and 501, and is served by the Durham and Southern, the Norfolk and Western, the Norfolk Southern, the Seaboard Air Line and the Southern railways. Pop. (1950) 70,307, (1940) 60,195 by the federal census. It is the seat of Duke university (q.v.), and is one of the leading tobacco markets and tobacco manufacturing centres of the country. Durham became a nationally known medical centre with the establishment of the Duke clinic.

In the city of Durham there are large cotton mills, hosiery mills and various other manufacturing industries. The assessed valuation of property in 1950 was \$250,000,000 and bank debts in 1949 amounted to \$1,221,779,000. The North Carolina College at Durham (Negro), Lincoln hospital (one of the finest in the country for Negroes) and the largest Negro life insurance company in the country are situated there. The tobacco industry of Durham was founded soon after the Civil War by W. T. Blackwell (1839-1904) and Washington Duke (1820-1905). The city was incorporated in 1869, became the county seat of the newly constituted county in 1881, and in 1921 adopted a council manager form of government. In the Bennett house near the city, Gen. J. E. Johnston on April 26, 1865, surrendered to Gen. William T. Sherman.

DURIAN, the fruit of *Durio zibethinus*, a tree of the family Bombacaceae, which attains a height of 70 or 80 ft., has oblong, tapering leaves, rounded at the base, and yellowish green flowers, and bears a general resemblance to the elm. The durian is cultivated in Sumatra, Java, Celebes and the Moluccas and northward as far as Mindanao in the Philippines, also in the Malay peninsula, in Tenasserim, on the Bay of Bengal, to 14° N. lat., and in Siam to the 13th and 14th parallels. The fruit is spherical and 6 to 8 in. in diameter, approaching the size of a large coconut, it has a hard external husk or shell, and is completely armed with strong pyramidal tubercles, meeting one another at the base and terminating in sharp, thorny points. On dividing the fruit at the joints of the carpels, where the spines arch a little, it is found to contain five oval compartments, each filled with a cream coloured, glutinous pulp, in which are embedded from one to five seeds about the size of chestnuts. The pulp and the seeds, which latter are eaten roasted, are the edible parts of the fruit. With regard to the taste of the pulp, A. R. Wallace (*The Malay Archipelago* [1872]) remarks, "A rich butter-like custard, highly flavoured with almonds, gives the best idea of it, but intermingled with it come wafts of flavour that call to mind cream cheese, onion-sauce, brown sherry

and other incongruities, it is neither acid, nor sweet, nor juicy, yet one feels the want of none of these qualities, for it is perfect as it is." The fruit, especially when not fresh from the tree, has an exceedingly offensive smell, which has been compared to that of rotten onions or of putrid animal matter.

DURIS, of Samos Greek historian, according to his own account a descendant of Alcibiades, was born about 340 B.C. He must have passed his early years in exile, since from 352 to 324 Samos was occupied by Athenian cleruchs, who had expelled the original inhabitants. He was a pupil of Theophrastus of Eresus, whom he met at Athens. When quite young he won a prize at the Olympic games, a statue by Hippis was set up to commemorate his victory (Pausanias, vi, 13, 5). He was for some time despot of Samos. Duris was the author of a history (*Historiae*) from the battle of Leuctra (371) down to the death of Lysimachus (281), and a life of Agathocles of Syracuse (both used by Diodorus), the annals (*ἁπορίαι*) of Samos, arranged according to the lists of the priests of Hera, and treatises on literary and artistic subjects. Plutarch (*Pericles*, 28) expresses doubt as to his trustworthiness, Dionysius Halicarnassensis (*De compos. verborum*, 4) criticizes his style and Photius (*cod.* 176) the arrangement of his work.

See Fragments in C. W. Müller, *Fr. Hist. Graec.*, ii, 446, where the passage of Pausanias referred to above and the date of Duris' victory at Olympia are discussed.

DURKHEIM, EMILE (1858-1917), French sociologist and philosopher, came of a rabbinical Alsatian family. His study of law, philosophy and social science, first in France and later in Germany, led to acceptance of the chair of sociology founded for him at Bordeaux in 1887, five years later he was called to Paris to teach sociology and pedagogy. Like Auguste Comte, whose successor he was, Durkheim studied society as a natural phenomenon to be treated as the physical scientists treat their subject matter. His books on the division of labour, suicide and primitive religion combine a bold and well considered theoretical analysis with monographic empirical material. A notable contribution is his concept of collective representation, the effect upon the individual of a synthesis of the reactions which the consciousness of individuals in society exercise on each other. With this concept he developed the view that society, to remain stable, must have a common value system. Durkheim's chief publications are *De la division du travail social* (1893), *Les Règles de la méthode sociologique* (1894), *Le Suicide* (1897), *Les Formes élémentaires de la vie religieuse* (1912, Eng. trans., 1915).

In 1897 Durkheim founded *L'Année sociologique*, which he edited annually.

DURKHEIM, a town in the Bavarian Palatinate, Germany, near the foot of the Hardt mountains, and at the entrance of the valley of the Isenach, 15 mi. NW of Spire on the railway Monheim Neustadt. Population 7,770. The town hall occupies the site of the castle of the princes of Leiningen Hartenburg. It is well known as a health resort for the grape cure and for the baths of the brine springs of Philipshalle which produce marketable salt. There is a brisk trade in wine. As a dependency of the Benedictine abbey of Limburg, built and endowed by Conrad II, Durkheim or Thurnheim came under the counts of Leiningen, who in the 14th century made it the seat of a fortress. It was often damaged in wars but was rebuilt after the French invasion of 1689. The ruins of the Benedictine abbey of Limburg lie about 1 mi. SW of the town, and in the neighbourhood rises the Kastanienberg, with ancient fortification of the Heidenmauer or Heathen wall.

DURLACH, a town in the Land of Baden, Germany, 2½ mi. by rail from Karlsruhe, with which it is connected by canal, on the left bank of the Pfünz at the foot of the vineyard covered Thurnberg. Pop. (1933) 18,658. It possesses a castle (1565), now a bar racks, and an ancient town hall. It has manufactures of brushes, chemicals, machinery, gloves, leather, tobacco, beer, vinegar and cucury, and considerable trade in market produce.

Durlach was bestowed by the emperor Frederick II on the margrave Hermann V of Zahringen as an allodial possession, but afterwards came into the hands of Rudolph of Habsburg. It was chosen as his residence by the margrave Charles II in 1565, and retained this distinction till the foundation of Karlsruhe in 1715, though it was almost totally destroyed by the French in 1688.

DUROC, GÉRAUD CHRISTOPHE MICHEL, DUC DE FAULT (1772-1813), French general, was born at Pont à Mousson (Meurthe et Moselle) on Oct. 25, 1772. He was gazetted second lieutenant (artillery) in the 4th regiment in 1793, and advanced steadily in the service. Captain Duroc became aide de camp to Napoleon in 1796, and distinguished himself at Isonzo, Brenta and Gradisca in the Italian campaigns of 1796-97. He served in Egypt, and was seriously wounded at Aboukir. His devotion to Napoleon was rewarded by complete confidence. He became first aide de camp (1798), general of brigade (1800) and governor of the Tuileries. After the battle of Marengo he was sent on missions to Vienna, St. Petersburg, Stockholm and Copenhagen. As grand marshal of the Tuileries he was responsible for the measures taken to secure Napoleon's personal safety whether in France or on his campaigns, and he directed the minutest details of the imperial household. After Austerlitz, where he commanded the grenadiers in the absence of General Oudinot, he was employed in negotiations with Frederick William of Prussia, with the elector of Saxony (December 1806), in the incorporation of certain states in the Confederation of the Rhine, and in the conclusion of the armistice of Znaim (July 1808). In 1808 he was created duke of Friuli, and after the Russian campaign he became senator (1813). He was in attendance on Napoleon at the battle of Bautzen (May 20-21, 1813) in Saxony, when he was mortally wounded, and died in a farmhouse near the battlefield on May 23.

The chief source for Duroc's biography is the *Moniteur* (May 31, 1797, Oct. 24, 1798, May 30, 1813, etc.).

DURRA, see KAFIR.

DURUY, JEAN VICTOR (1811-1894), French historian and statesman, was born in Paris. He studied under Michelet at the École Normale Supérieure, and taught at the Collège Henri IV at Paris for over a quarter of a century. Already known as a historian by his *Histoire des Romains et des peuples soumis à leur domination* (2 vols., 1843-44), he was appointed minister of education in 1863.

Among his measures may be cited his organization of higher education ("enseignement spécial"), his foundation of the "conférences publiques," which later became universal throughout France, and of a course of secondary education for girls by lay teachers, and his introduction of modern history and modern languages into the curriculum both of the *lycées* and of the colleges. He greatly improved the state of primary education in France and proposed to make it compulsory and gratuitous, but was not supported in this project by the emperor. In 1884 he was elected to the Academy. He died on Nov. 25, 1894.

Duruy's fame rests mainly on the revised edition of his Roman history, which appeared in a greatly enlarged form in 7 vol. under the title of *Histoire des Romains depuis les temps les plus reculés jusqu'à la mort de Théodose* (1879-85), Eng. trans. by W. J. Clarke, 6 vol., 1883-86. He also wrote *Histoire des Grecs* (3 vol., 1886-91, Eng. trans., 4 vol., 1892), *Histoire de France de 1453 à 1815* (1886, new enlarged ed. 1891), and other works on French history.

A memoir by Ernest Lavisse appeared in 1895 under the title of *Un Ministre. Victor Duruy*. See also the notice by Jules Simon (1895) and S. Monod, *Portraits et souvenirs* (1897).

DURYEY, an anthracite mining borough of Luzerne county, Pa., U.S.A., on the Susquehanna river and the Lackawanna railroad, 8 mi. S.W. of Scranton. The population in 1950 was 6,676 and 8,275 in 1940.

The borough, originally called Babel because the first inhabitants came from so many different countries and spoke so many different languages, was called Duryea after Abram Duryea, who began working coal mines in that region in the middle of the 19th century.

DU RYER, PIERRE (c. 1606-1658), French dramatist, was born in Paris. His masterpiece, *Scévole*, probably dates from 1644 (the date generally given is 1646). *Illecebre* (1637) was so popular that the abbé d'Aubignac knew it by heart. Among du Ryer's other works may be mentioned *Saul* (printed 1642) and a comedy *Les Vendanges de Suresnes* (printed 1635, probably played 1633).

See H. C. Lancaster, *Pierre du Ryer Dramatist* (1913).

DUSART (DU SART), CORNELIS, the younger (1660-1704), Dutch painter and engraver. He was born at Haarlem on April 24, 1660, and became one of the most distinguished pupils of Adriaen van Ostade, following his master closely both as regards style and subject matter. His engravings are much sought after. He died at Haarlem on Oct. 1, 1704.

DUSE, ELEONORA (1859-1924), Italian actress, belonged to a family of actors from Chioggia, near Venice. Her grandfather, Luigi Duse, a celebrated actor of Goldoni plays, created the 18th century Venetian masque of Giacomotto, round which a whole dialect repertory turned. Born on a tour in Lombardy on Oct. 3, 1859, Eleonora Duse was carried to her christening at Vigevano in a gilt theatrical property box, some Austrian soldiers presented arms, thinking it was a reliquary. She acted the part of Cosette in *Les Misérables* at the age of four in a booth at Chioggia. At Verona she played Juliet when just 14, and drew public attention by her love of flowers and the use she made of them in her art. The incident is always referred to as "the device of the roses" (*la trovata delle rose*).

About this time her mother, to whom she was passionately attached, died, and thrown on her own resources, often in dire poverty, she passed from one travelling company to another, eventually reaching fame through sheer hard work, no less than by genius and the exceptional beauty of her speaking voice. She acted in *Alcibiades* of Felice Cavallotti, in *Orfeo* of Alfieri, and took the part of Shakespeare's Ophelia with success. She gained wider recognition in 1878 when, one night at Naples, she was called upon suddenly to take the leading part in *Les Fourchambaults* by Augier. In the following year, after securing a real triumph in the part of Zola's *Thérèse Raquin*, Cesare Rossi engaged her for his famous company as *prima diva* and she added *La Princesse de Bagdad* to her repertory. A memorable year was 1882: she saw Sarah Bernhardt act at Turin in *La Dame aux Camélias* of Dumas fils, and felt inspired to give her own interpretation of Marguerite Gautier—"fille galante, extrêmement distinguée," a character which both actresses idealized. The Frenchwoman, less realistic and temperamental, possessed a more subtle style, but, in certain scenes, the passionate, almost volcanic, powers of the Duse admitted of no rival. The greatest triumph, perhaps, in her career was gained in this part, and she was induced to act in Paris in 1897, when the Parisians were taken by storm, Sarah Bernhardt leading the applause. She also acted in *Frou Frou* and *La Femme de Claude*. Her *Magda*, in the opinion of Sudermann the author, was never surpassed. In the character of *Mirandolina* (*La Locandiera* of Goldoni) she also showed a remarkable gift for light comedy. She created the character of Santuzza in *La Cavalleria Rusticana*, given for the first time in 1884, and such was her success that Verga said the play belonged as much to her as to him. Her acting during all this period was characterized by realism devoid of any excess, hers was the highest kind of romantic realism which had passed through the flame of intense feeling. Coquelin the elder said of her: "No one draws from humanity as she does, she is passionately beautiful and great." Her own words still further help to explain her vivid and varied personality: "How I have loved life!" she wrote to a friend, and again "There are a thousand women within me, and each one makes me suffer in turn."

Eleonora Duse was a woman of wide culture, her intellectual life had been greatly influenced early in life through a close friendship with Arrigo Boito, the composer, whose sound criticism proved of considerable value to her art. The books she steeped herself in included the writings of Pascal, Keats, and Thomas à Kempis, *The Letters of St. Catherine of Siena*, *The Confessions of St. Augustine* and *L'Action* by Maurice Blondel.

Essentially religious by nature, she was untouched by organized religion. She traveled a great deal both for her profession and for pleasure. Her greatest love was called her "impassioned pilgrim." She had no fixed home, the nearest approach to one was her summer house at Asolo. She lived simply but spent large sums on producing plays and in financing her company of actors whom she would sometimes keep idle for long spells on account of health. She made her first appearance in Paris in 1884, went to London and New York in 1893, and to Moscow in 1892 and 1897, and to Egypt. She always particularly liked acting in Vienna.

Her restless, soaring spirit eventually grew weary of Dumas and Augier, finding in *La Dame aux Camélias* alone "a thread of gold to hold together the string of false pearls", and, towards middle age, the Duse turned definitely to poetry and "les oeuvres de pensee". In 1896 she commissioned Panzacchi to translate *L'Abbesse de Bourges*, which she acted in Rome with so much success that Ruan wrote her a letter full of praise and gratitude. At this time she passed under the spell of the later works of Ibsen, to be closely followed by the aestheticism of D'Annunzio. In Scandinavian dramatism she saw the poet more vividly than the scourger of society. Ellida *The Lady from the Sea*, with whom she felt some affinity, was her favourite heroine. Ibsen was not altogether satisfied with her interpretation of Hedda Gabler, he is reported to have said as he left the theatre "She believes Hedda to be a neurotic, but she is absolutely wrong."

Her life consuming friendship with D'Annunzio began in 1897, they parted in 1902, only to meet 18 years later at a patriotic gathering in Milan. D'Annunzio immortalized their friendship in *Il fuoco*, the novel of the lagoons, incorporating many of her letters and sayings. *La Città morta* he had dedicated to Sarah Bernhardt, *La Gioconda* he wrote for "Eleonora Duse of the beautiful hands" and wrote many other plays under her enthusiastic inspiration. She took up the cause of D'Annunzio as a dramatist with almost mystic exaltation, and threw all her energies into trying to found a theatre which was to be a D'Annunzio Bayreuth for the glory of a pure art. A site was offered to her on the shores of Lake Albano, near the Baths of Diana, but to her grief the scheme fell through, chiefly because the public did not recognize the real Duse in the drama of D'Annunzio. *La Gioia* was hissed at Naples in 1898 and no better success attended *Sogno di un mattino di primavera*, but she won some applause for *Francesca da Rimini* in 1902. Undaunted, the Duse insisted upon acting only the plays of D'Annunzio when she went to America in 1902-3 with Erneste Zaccanti, and, in spite of financial losses, she refused to revive old favourites. Some people think that D'Annunzio had an enervating effect upon her art, and that her recitation tended towards monotony, while, in the opinion of others, her style lost rough edges and gained in classical grandeur, and her general culture was enriched.

At the height of her fame in 1909, Eleonora Duse definitely

[illegible]

Thus, the π -conjugated polymer backbone is a key factor in determining the photophysical properties of the polymer.

or change of style. She continued to play *Thénais*, *D'Annunzio* and *La Porta Chiusa* of Marco Praga. After touring Italy she made her last appearance in London in June 1923 when she acted to far fuller houses than in the heyday of her glory. She courageously accepted a tour in America the following spring, where she also received a triumphal reception. But her health was broken, and often she had to be revived with oxygen after a performance, though her vitality never gave out during the play. She died from the results of a chill at Pittsburgh on April 21, 1924, at the age of 64. She was pitifully anxious not to die far away from Italy, and gave feverish orders, almost with her last breath, to pack up quickly so as to catch the boat home. Italian emigrants knelt on the quay as her coffin was lowered on to the battleship "Duilio" at New York, and national mourning was proclaimed in Italy. Her countrymen desired to see her laid at rest with other illustrious Italians in Santa Croce at Florence, but they respected her wishes to be quietly buried at Asolo.

DUSSEK, JAN LADISLAV (1761-1812), Bohemian pianist and composer, was born at Caslar, Bohemia, on Feb. 9, 1761, the son of the cathedral organist. He played in public at the age of 5, became a choir boy, and then studied theology at Prague. He found a patron in Count Manner, whom he accompanied to Malines, Belgium. He was organist there for some time, then at Bergen-op-Zoon. He then spent some time at Amsterdam and the Hague, and attained a great reputation as a pianist. He had already written a large number of sonatas for the piano forte with string accompaniments, when he went to Hamburg about 1783 to study under Karl Philipp Emanuel Bach. Dussek found a patron in Prince Radziwill and in Paris in Marie Antoinette. He spent twelve years in London from 1792 onwards, marrying in that year a singer, the daughter of Domenico Corri. Later he entered into partnership with Corri in a music shop, which failed. He left England in 1800 for Hamburg. His later patrons were Prince Louis Ferdinand of Prussia, the prince of Ysenburg and finally Talleyrand. In Talleyrand's household, where he lived from 1800 until his death at St. Germain en Laye (Nov. 20, 1812) he was a great and honoured figure. A complete list of Dussek's works will be found in Grove's *Dictionary of Music and Musicians*. It includes a large number of piano forte works and a considerable amount of chamber music. His sonatas for the piano forte represent him at his best.

DUSSELDORF, a government district (*Regierungsbezirk*) of Prussia, Germany. Area 2,121 sq. mi. Pop. (1939) 4,500,000. (2) A town, the capital of the district Pop. (1939) 539,000. It is situated on the right bank of the Rhine 24 mi. north of Cologne (by rail) from Cologne. It was long a place of importance until, in 1288, it was raised to the rank of a town by Adolf of Berg. It suffered severely in the Thirty Years' War and the War of the Spanish Succession, but recovered its importance under the patronage of the elector John William of Brandenburg who dwelt in the castle many years until his death in 1705. In 1795 the town after a violent bombardment was surrendered to the French, and after the peace of Lunéville it was incorporated into the French Republic. In 1805 it became the capital of the duchy of Berg, and in 1815 it passed with the town to Prussian possession. After 1870, it developed into an important industrial and commercial town. It is the commercial and manufacturing centre of the Wupper and Ruhr areas and is the centre of the metallurgical, engineering, machinery, glass and chemical industries, other important industries are paper, weaving, spinning, silk, dyes, furniture and brewing. It is an important railway junction. The extensive quays provide a station for large steamers ordinarily sailing to England.

Northern Europe and certain Mediterranean ports. The famous Academy of Painting founded by the elector Charles Theodore in 1767 was reorganized by King Frederick William III in 1822. Among the celebrities of the town are Johann Georg and Frederick Henrich Jacobi, Henrich Heine and Peter von Cornelius, and Louise Dumont, who founded a theatre. Large international industrial exhibitions were held at Düsseldorf in 1880, 1902 and 1937. In order to facilitate better city planning in regard to streets, traffic and parks several adjacent towns and suburbs (Benrath, Garath, Urdenbach, Kassewerth, Lohausen and Ludeberg) were incorporated into Düsseldorf on Aug. 1, 1929. During World War II the city suffered severely from frequent British bombing attacks.

See H. Ferber *Historische Wanderung durch die alte Stadt Düsseldorf* (Düsseldorf, 1889-90), W. Wilden, *Grundlagen und Trübräume der Wirtschaft in Düsseldorf* (1923), H. Stolz, *Düsseldorf* (1925).

DUST Dust is earth or other solid matter in a fine state of subdivision, so that the particles are light enough to be easily raised and carried as a cloud by the wind. The presence of dust in the atmosphere is obvious on the most casual inspection. Particles of dust, varying from the motes in the sunbeam to big flakes of soot, are readily visible to the naked eye. The origin of the dust is varied in character. Smoke from domestic and factory chimneys contains particles of carbon (soot), as well as small particles of ashes and drops of liquid tar. These particles are carried by the wind, and even spread upward through considerable heights by the turbulent or eddy motion of air (see *METEOROLOGY: The Tertiary Circulations*).

Over the deserts coarse dust is raised from the ground by wind storms, and can be carried for thousands of miles by the wind. The "red rain" which has been observed in Europe from time to time is due to the washing down of desert dust which has originated in tropical deserts. A notable example of "red rain" occurring on Feb. 21 and 22, 1903, is described in the *Quarterly Journal Roy. Met. Soc.*, xxx, 1904 p. 57, where it is shown that the dust must have travelled from north west Africa round the western edge of an anticyclone over southern Europe. The amount of dust which fell in England during the two days in question was estimated at about ten million tons. The *harmattan*, a dry, easterly wind which blows off the west coast of Africa between Cape Verde and Cape Lopez, carries with it quantities of dust, causing thick haze for a distance up to 15 m. from the shore. Enormous quantities of volcanic dust are poured into the atmosphere by the eruption of volcanoes. The eruption of Krakatoa near Java in 1883 produced, among many effects, a vast cloud of small particles which is said to have taken two years to settle down completely. The dust from Krakatoa produced the most extraordinary colours in the sky. Even in the British Isles sunsets of unusually gorgeous colours were observed. Meteoric matter disintegrating in the air is another source of atmospheric dust. A phenomenal dust storm visited the United States in May 1934. Rising from the parched soil of the Western plains, where drifts as deep as six inches often covered the highways, a vast cloud of dust moved slowly eastward, hung for a time in yellow haze over the cities along the coast and finally was precipitated in the Atlantic Ocean.

The particles of dust or soot, from whatever source they originate, are distributed over a wide area by the wind. Granted a sufficient wind velocity, the smoke from the largest city will be distributed over such a wide area, and through so great a volume of air, that it cannot acquire a sufficient density to be troublesome. But when the wind falls below a certain limit, it ceases to be an effective distributor. Another factor of importance in connection with the concentration of smoke is the turbulence in the atmosphere, which scatters the smoke through a greater range of height than it would otherwise attain. When there is an increase of temperature with height (i.e., an inversion) instead of the normal decrease, turbulence is suppressed, since inversions of temperature at the ground are usually associated with light winds, they generally give smoke fogs in large towns.

The rate of settlement of spherical particles of dust through a still atmosphere is given approximately by the formula,

$$V = \text{density} \times R^2 \times 12 \times 10^5$$

where V is the velocity in centimetres per second and R is the radius of the particle in centimetres. Thus a particle of unit density and of diameter 1 micron will fall through still air at a rate of about 0.003 centimetres per second, which is equivalent to a fall of 30 metres (100 ft) in 278 hours, during which time a wind of 10 m.p.h. would carry it 2,780 miles. It is thus readily seen that smoke particles can travel over immense distances under favourable conditions. A drop of water of diameter 10 microns would fall with a velocity of 3 cm/sec or roughly 10 metres in one hour.

The first investigations of the amount of dust in the atmosphere were those of John Aitken in 1880. Aitken succeeded in showing that water drops will not form, even in supersaturated air, in the complete absence of solid nuclei upon which the molecules of water can collect. It was but a step further, to utilize this idea to count the number of condensation nuclei in a given volume of air. Aitken's method consisted in placing the air under examination in an airtight receiver and saturating it with water vapour. It was then caused to expand adiabatically until condensation was produced, the drops being collected on a reticule and counted by the aid of a short focussed lens. Certain precautions were necessary in carrying out this procedure. It was found that if more than 500 nuclei were present in each cubic centimetre of air, they would not all form water drops. In such cases it was necessary first to dilute the air with air which had been carefully filtered, subsequently allowing for the dilution in computing the number of particles per second. Aitken's method was applied in thousands of tests in different parts of the world, and in no case was the air found to be completely free of nuclei. The numbers of particles per c.c. in cities such as London and Paris were often found to exceed 100,000. Fridlander used Aitken's dust counter on a voyage across the Atlantic and never found values below 2,000 per c.c. but in crossing the Pacific and Indian oceans he found values as low as about 250 per c.c. But we can safely conclude that air, no matter where it is sampled, contains an ample supply of particles capable of acting as condensation nuclei. The instrument which Aitken devised for counting the particles suspended in air was called a "dust counter," but subsequent research has shown that the particles which Aitken counted were not dust in the ordinary sense of the word, but what are known as hygroscopic nuclei.

The only effective nuclei are particles of certain hygroscopic salts, in particular the chlorides of sodium and magnesium derived from salt spray, and sulphates. Ordinary dust, except such particles as may be hygroscopic, will not act as nuclei for condensation, and particles of soot, being of a larry nature, tend to repel water rather than to attract it. The hygroscopic nuclei are so small as to be in general invisible in the field of a high-power microscope, but on account of their hygroscopic properties they are capable of producing water drops in air whose humidity falls short of saturation. Thus particles of common salt will produce condensation when the relative humidity is only 75%, and are thus capable of producing fogs at times when the conditions do not otherwise seem favourable for their formation.

It was first suggested by Wigand (A. Wigand, *Meteor. Zeitschrift* 30 p. 10 Jan. 1913) that the particles counted by Aitken's dust counter were not dust in the ordinary sense of the word. Wigand compared the figures obtained by Aitken's method in air which was artificially made dusty and found that the number of condensation nuclei per c.c. was not dependent on the amount of dust introduced into the atmosphere. This is confirmed by Owen's observations. A recent investigation by Boylan (*Proc. Roy. Irish Acad.* vol. 37A N° 6, 1926) shows very definitely that the dust and nuclei are different, and that ordinary dust particles will not act as nuclei for condensation.

The horizontal visibility of objects on the earth's surface depends upon the degree of pollution of the atmosphere. Poor visibility is due to the obscuration of the atmosphere by water-drops or by solid particles. The condition known as haze is due to the presence in the atmosphere of small solid particles, whose diameter is about 5 micron (0.005 mm.), together with varying quantities

of water drops. In a series of observations of haze by Owens it was found that in some cases no water drops were present, while in other cases large numbers of water drops were found. The distinction is largely a question of relative humidity, since haze is probably always a mixture of insoluble particles and hygroscopic nuclei. If the relative humidity is low, the haze, if direct, is almost entirely due to small solid particles of dust whose diameter is of the order of $\frac{1}{2}$ micron, but if the humidity increases sufficiently, condensation takes place on the hygroscopic nuclei, and the haze changes into a true mist. Similarly fog may be divided into two classes—smoke fogs and water fogs. The diameter of the solid particles in a smoke fog vary from $\frac{1}{2}$ micron up to several microns, while the diameter of water drops in a water fog vary from 5 to 20 microns. The fine smoke particles which produce the dust horizon frequently seen in the British isles have diameters of about 8 microns, while the Indian dust horizon consists of blown sand of similar size.

The most troublesome aspect of atmospheric dust is provided by the smoke produced in great cities. The problem of pollution produced by smoke has been the study of a special Advisory Committee on Atmospheric Pollution. The work of this committee has been summarized by Sir Napier Shaw and Dr. J. S. Owens in *The Smoke Problem of Great Cities*. Smoke as it issues from the chimney consists of particles of soot of varying sizes as well as acid products of combustion, small particles of ash, and small drops of tar. The larger aggregations of soot fall in the near neighbourhood of their source, while the smaller particles of dust enter rather less than one micron air carried to considerable distances. Shaw and Owens describe a variety of methods for the detection and measurement of the quantities of different forms of pollution in the atmosphere, and the reader is referred to their treatise for fuller details of these methods. Of particular interest, however, is the jet dust counter devised by Dr. J. S. Owens, depending upon the principle that when air containing dust and a sufficient quantity of water vapour has its pressure suddenly reduced, there is a fall of temperature and a condensation of moisture into water drops.

It is not clear how the ordinary dust particles become attached to their share of water, but it appears probable that the particles which are hygroscopic become nuclei of condensation and that the condensed water captures the dust. When the dust-bearing water drops are brought into contact with a glass surface they adhere to it. In the Owens dust counter the dusty air is drawn through a slit as a fine ribbon shaped jet, and impinges on a coverglass placed at a millimetre from the slit. The air is first passed through a damping chamber in which it acquires sufficient moisture to produce condensation. The lowering of pressure by which the air is drawn through the jet is sufficient to produce condensation in the air striking the coverglass. As the velocity falls off, the pressure and temperature rise, and the waterdrops evaporate from the coverglass, leaving the dust deposited. By a careful adjustment of the amount of air drawn through the jet, a record is obtained on which the dust particles can be examined and counted by means of a microscope with $\frac{1}{2}$ inch oil immersion objective.

The results derived by the use of the Owens dust-counter show a wide variation in the number and nature of the particles in the atmosphere. For example, in a dense fog on Jan. 22, 1922, there were 21,750 particles per cubic centimetre. The average diameter of the particles was 0.85 microns, but a large proportion had diameters twice as great as the average. Somewhat similar results were obtained from a fog on Oct. 26, 1921, but in this case there were numerous small spherical particles of diameters up to 0.85 microns. A slight haze in dry sunny weather yielded 100 to 200 particles per cubic centimetre, of sizes from 0.3 microns up to 1.7 microns. Further, it was found that when the damping chamber of the Owens dust counter was slightly warmed, and a large quantity of air drawn through the jet, the condensed water flowed out sideways in streams, and on evaporation left the soluble matter crystallized in the dried-up stream beds. The crystals could then be examined microscopically and microchemically. The deposit on the coverglass frequently showed needle shaped and rhomboid crystals, sometimes with a tarry deposit. Most of the records

obtained showed a number of transparent spherical particles, occasionally accounting for as much as 50% of the total number of particles counted. When very small these particles appear opaque, but when the diameter exceeds about 0.75 micron they show a bright centre. The spherical particles are insoluble in water, xylol, and cedarwood oil.

Perhaps the most remarkable fact brought out by the observations mentioned above is the remarkable uniformity as to the size of the particles. Shaw and Owens in the book referred to (p. 185) give a comparison between numbers of particles counted by the jet dust counter, and the total impurity present in the atmosphere, showing a remarkably close proportionality. The number of particles counted should therefore give a measure of the degree of obscenity of the atmosphere. These numbers bear no relationship to the numbers of particles obtained in the Aitken dust counter, since the latter may give extremely high values in apparently clear air.

The fact that the particles measured by the Owens dust counter differ from those observed by Aitken is also confirmed by the observations made by Owens while crossing the Atlantic. No dust was to be recognized in any of the records, though some showed numbers of crystals, some of which were not hygroscopic, and were only sparingly soluble in water. Aitken, on the other hand, never found less than about 2,000 particles in one cubic centimetre of air over the Atlantic.

Optical Effects.—The scattering of light by small obstacles was exhaustively studied by the late Lord Rayleigh, who showed that true scattering only takes place when the diameter of the obscuring particles is smaller than the wave length of the incident light. Rayleigh showed also that the coefficient of scattering was inversely proportional to the fourth power of the wave length, so that light in the blue end of the spectrum is scattered more than light in the red end of the spectrum. Thus a cloud of tobacco smoke (consisting of small liquid particles of about 2 microns in diameter) or a smoke haze in the atmosphere will appear blue by scattered light, while the sun appears red when viewed through a thick smoke fog, but white when viewed through a country fog consisting of water drops. Water drops are too large to produce true scattering, their effect being of the nature of diffraction and reflection which is almost equally effective for all wave lengths. Hence water drops appear white, whether viewed by scattered or direct solar radiation.

During the first two or three years after the eruption of Krakatoa a reddish brown corona was often observed around the sun. It had an angular radius of 22° to 23° , and was $10''$ to $12''$ wide. Pernter explained this phenomenon, which was known as Bishop's ring, as a result of diffraction of sunlight by small dust particles, and assuming the particles to be spherical he found their diameter to be 1.85 microns. It is of interest to combine this figure with Stokes's formula for the rate of fall of particles. We find their rate of fall should be 0.02 cm/sec or 10 km in a time between one or two years.

Another aspect of the optical effects of dust in the atmosphere upon sunlight relates to the loss of ultra-violet rays which is directly produced by dust and smoke pollution. In the *Times* of Dec. 22, 1924, Professor Leonard Hill gave a comparison of the relative amounts of ultra-violet light at different places in the British isles, showing the lowest values in the centre of London. In view of the importance of ultra violet rays to human health, the results are highly suggestive.

It has been frequently suggested that a smoke fog such as a London fog might be penetrated by the longer infra-red rays. On theoretical grounds we should expect that infra-red rays of wave length large by comparison with the mean diameter of the smoke particles (0.8 micron), should show some degree of penetration. In Wood's *Physical Optics* (3rd Edition p. 416), there is a statement that a film of smoke which was absolutely opaque to light was transparent to infra red rays of wave length 100 microns. This result in itself is not suggestive of any practical solution of penetration, since there still remain the problems of finding not only suitable sources for such radiation but also a means of rendering visible the rays which have penetrated the fog.

The problem is a long way from solution, and no definite observations of the penetration of fogs by infra red rays of different wavelength appear to have been published.

Country fogs composed of drops of water whose diameter is of the order of 10 microns, show no appreciable selective effect in the transmission of light, and there is no obvious reason for supposing that infra red rays would penetrate such fogs.

F Entwistle (*Jour. Roy. Aer. Soc.* vol. xxxi, p. 374, 1928) reproduces two interesting photographs by C. J. P. Cave, of a landscape—the one photograph taken in the usual way without a screen, and the second with a red screen, which cuts out all the blue light. The first shows a light fog, while in the second only slight traces of the fog are visible.

Vulcanism.—In *Physics of the Air*, W. J. Humphreys has discussed in considerable detail the effect of clouds of volcanic dust on solar and terrestrial radiation. He finds that these clouds have an inverse green house effect, in that they would obstruct the inward passage of solar radiation more than the outward passage of terrestrial radiation. For since solar radiation at its point of maximum intensity has a wave length of a little less than half a micron, it would be reflected rather than scattered by the dust particles whose diameter is of the order of 2 microns. Terrestrial radiation, on the other hand, has a wave length of about 12 microns at the point of maximum intensity, and should therefore be scattered by the dust particles in accordance with Rayleigh's law. On this basis Humphreys evaluates the coefficients of attenuation of solar and terrestrial radiation by volcanic dust, and concludes that a shell of volcanic dust is some thirty times more effective in shutting out solar radiation than it is in keeping in terrestrial radiation. Humphreys' computation is admittedly a rough approximation only. It assumes that all the dust is uniformly of the size of the particles which give Bishop's ring by diffraction. This we know to be incorrect. The wonderfully coloured sunsets produced by Krakatoa dust indicated a scattering of solar rays by dust particles of a diameter considerably less than 2 microns. Such dust would scatter both direct solar and terrestrial radiation, in proportion to the inverse fourth power of their wavelengths. This would increase the ratio of 30:1 given above.

Humphreys develops in considerable detail the theory that the emission of large quantities of volcanic dust into the atmosphere can produce large variations of climate, of a sufficient magnitude to account for ice ages. It is clearly established that after the eruption of Krakatoa in 1883 there were marked changes in the pyrheliometric measurements of solar radiation (Arcrowski, *Annals New York Acad. Sci.* 26, 1915, p. 149, and Kimball, *Monthly Weather Review*, 46, 1918, p. 355). The theory, known as the vulcanism theory, has by no means met with general acceptance, though there is some evidence, especially in eastern Australia, of the association of glaciation with volcanic activity, which appears to bear out the theory. In any case, volcanic dust may well have been a deciding factor in starting glaciation when other factors were also favourable. For further details the reader is referred to Humphreys' *Physics of the Air*, and to works on climatology.

DUTCH AUCTION. A form of auction in which the property for sale is put up at a certain figure, and if not bid for at that price, offered successively at lower prices until a bid is obtained. The starting price is assumed to be higher than the seller hopes to get. (See AUCTIONS AND AUCTIONEERS.)

DUTCH EAST INDIA COMPANY, THE (*Oostindische Verreemde Maatschappij*), a body founded by a charter from the Netherlands states general on March 20, 1602. It had a double purpose: first to regulate and protect the already considerable trade carried on by the Dutch in the Indian ocean, and then to help in prosecuting the long war of independence against Spain and Portugal. Before the union between Portugal and Spain in 1580-81, the Dutch had been the chief carriers of eastern produce from Lisbon to northern Europe. When they were shut out from the Portuguese trade by the Spanish king they were driven to sail to

the East in order to make good their loss. Unsuccessful attempts were made to find a route to the East by the north of Europe and Asia which would have been free from interference from the Spaniards and Portuguese. It was only when these failed that the Dutch decided to intrude on the already well known route by the Cape of Good Hope, and to fight their way to the Spice islands of the Malay archipelago. A first expedition, commanded by Cornelius Houtman, a merchant long resident at Lisbon, sailed on April 2, 1595. It was provided with an itinerary or book of sailing instructions drawn up by Jan Huyghen van Linschoten,¹ a Dutchman who had visited Goa. The voyage was marked by many disasters and losses, but the survivors, who reached the Texel on their return on Aug. 20, 1597, brought back some valuable cargo and a treaty made with the sultan of Bantam in Java.

These results were sufficient to encourage a great outburst of commercial adventure. Companies described as "Van Ferne"—that is, of the distant seas—were formed, and by 1602 from 60 to 70 Dutch vessels had sailed to Hindustan and the Indian archipelago. On those distant seas the traders could neither be controlled nor protected by their native government. They fought among themselves as well as with the natives and the Portuguese, and their competition sent up prices in the eastern markets and brought them down at home. Largely at the suggestion of Jan van Oldenbarnevelt, and in full accordance with the economic principles of the time, the states general decided to combine the existing separate companies into one united Dutch East India Company, which could discharge the functions of a government in those remote seas, prosecute the war with Spain and Portugal, and regulate the trade. A capital estimated variously at a little above and a little under 6,500,000 florins, was raised by national subscription in shares of 3,000 florins. The independence of the states which constituted the United Netherlands was recognized by the creation of local boards at Amsterdam, in Zealand, at Delft and Rotterdam, Hoorn and Enkhuizen. The boards directed the trade of their own districts, and were responsible to one another, but not for one another as towards the public. A general directorate of 60 members was chosen by the local boards. Amsterdam was represented by 20 directors, Zealand by 12, Delft and Rotterdam by 14, and Hoorn and Enkhuizen also by 14. The real governing authority was the "Collegium," or board of control of 17 members, of whom 16 were chosen from the general directorate in proportion to the share which each local branch had contributed to the capital or joint stock. Amsterdam, which subscribed a half, had eight representatives, Zealand, which found a quarter, had four, Delft and Rotterdam, Hoorn and Enkhuizen had two respectively, since each of the pairs had subscribed an eighth. The 17th member was nominated in succession by the other members of the United Netherlands. A committee of ten was established at The Hague to transact the business of the company with the states general. The "collegium" of 17 nominated the governors-general who were appointed after 1603. The charter, which was granted for 21 years, conferred great powers on the company. It was endowed with a monopoly of the trade with the East Indies, was allowed to import free from all custom dues, though required to pay 2% on exports, and charged with a rent to the states. It was authorized to maintain armed forces by sea and land, to erect forts and plant colonies, to make war or peace, to arrange treaties in the name of the stadtholder, and to coin money. It had full administrative, judicial and legislative authority over the whole of the sphere of operations, which extended from the west of the Straits of Magellan westward to the Cape of Good Hope. Its headquarters were early fixed at Batavia in Java. Only the main

¹Linschoten was born at Haarlem in or about 1563. He started his travels at the age of 16 and, after some years in Spain, went with the Portuguese East India fleet to Goa, returning in 1589. In 1594 and 1596 he took part in the Dutch Arctic voyages, and in 1598 settled at Enkhuizen where he died on Feb. 8, 1611. His *Nieuwgezac d'Amsterdam* (1595-96) is a compilation based partly on his own experiences, partly on those of other travellers with whom he came in contact. It was translated into English and German in 1598, two Latin versions appeared in 1599 and a French translation in 1610. The English version was reprinted for the Hakluyt Society in 1885. Large selections, with an Introduction are published in C. Raymond Beazley's *Voyages and Travels*, vol. II (English Garner, 1903).

dates of its progress can be mentioned here. By 1619 it had founded its capital in Batavia in Java on the ruins of the native town of Jacatra. It expelled the Portuguese from Ceylon between 1638 and 1658, and from Malacca in 1641. Its establishment at the Cape of Good Hope, which was its only colony in the strict sense, began in 1652. A treaty with the native princes established its power in Sumatra in 1667. The flourishing age of the company dates from 1605 and lasted till the closing years of the century. When at the summit of its prosperity in 1669 it possessed 150 trading ships, 40 ships of war, 10,000 soldiers, and paid a dividend of 40%. In the last years of the 17th century its fortunes began to decline. Its decadence was the result of a variety of causes. The rigid monopoly it enforced wherever it had the power provoked the anger of rivals. When Pieter Both, the first governor general, was sent out in 1608, his instructions from the board of control were to see that Holland had the entire monopoly of the trade with the East Indies, and that no other nation had any share whatever. The pursuit of this policy led the company into violent hostility with the English, who were also opening a trade with the east. Between 1613 and 1632 the Dutch drove the English from the Spice Islands and the Malay archipelago almost entirely. The English were reduced to a precarious footing at Bantam in Java. One incident of this conflict the torture and judicial murder of the English factors at Amboyna in 1623, caused bitter hostility in England. The success of the company in the Malay archipelago was counterbalanced by losses elsewhere. It had in all eight governments Amboyna, Banda, Ternate, Macassar, Malacca, Ceylon, Cape of Good Hope and Java. Commissioners were placed in charge of its factories or trading posts in Bengal, on the Coromandel coast, at Surat and at Gambroon (or Bunder Abbas) in the Persian gulf, and in Siam. Its trade was divided into the "grand trade" between Europe and the east, which was conducted in convoys sailing from and returning to Amsterdam, and the "Indies to Indies" or coasting trade between its possessions and native ports.

The rivalry and hostilities of the French and English gradually drove the Dutch from the mainland of Asia and from Ceylon. The company suffered severely in the War of American Independence. But it extended and strengthened its hold on the great islands of the Malay archipelago. The increase of its political and military burdens destroyed its profits. In the early 18th century it was already embarrassed, and was bankrupt when it was dissolved in 1798, though its credit remained unshaken, largely, if its enemies are to be believed, because it concealed the truth and published false accounts. In the later stages of its history its revenue was no longer derived from trade, but from forced contributions levied on its subjects. The immediate causes of its destruction were the conquest of Holland by the French revolutionary armies, the fall of the government of the stadtholder and the establishment of the Batavian republic in 1798.

BIBLIOGRAPHY—The great original work on the history of the Dutch East India company is the monumental *Beschriving van oost en nieuw oost Indien* (Dordrecht and Amsterdam, 1724), by François Valentyn, in 8 vol., folio, profusely illustrated. Two modern works of the highest value are J. K. de Jonge, *De Opkomst van het Nederlandsche Gezag in oost Indien*, 13 vol. (The Hague and Amsterdam, 1865–83); J. J. Mevius, *Geschiedenis van de Nederlandsche oost-Indische Bezittingen*, 3 vol. (Delft and The Hague, 1892–75). See also John Crawford, *History of the Indian Archipelago* (Edinburgh, 1820); Clive Day, *The Dutch in Java* (New York, 1904); Sir W. W. Hunter, *A History of British India* (1899); Pierre Bonassieux, *Les Grandes Compagnies de commerce* (1892).

DUTCH LANGUAGE. Dutch is spoken in Europe by about 15,000,000 people spread over the kingdom of the Netherlands, the northern half of Belgium and the northern part of the French *département* of the Nord. Outside the continent of Europe it is spoken in Indonesia by the Dutch who live there, in Dutch Guiana and the Dutch Antilles.

Cape Dutch (Afrikaans), spoken in the Union of South Africa, has developed into an independent language, its resemblance to Dutch, however, is very great for although its grammar has been considerably simplified, its vocabulary has for the greater part remained the same as that of High Dutch.

In the United States of America there are about 250,000 peo

ple whose mother tongue is Dutch, and in Canada the number is estimated at 125,000. In Ceylon, where Dutch was used in the 18th century as a church and government language, it is almost extinct, only a few Dutch words now remain.

At an early date the language of the Netherlands occupied an independent position among the Low German dialects spoken along the coasts of the North sea and Baltic from Dunkirk to Poland. At first it was chiefly the language of western Flanders (with the world market Bruges), which was dominant, but in the course of the 15th century Brabant came more to the fore. Antwerp at the height of its prosperity was a metropolis of about 200,000 inhabitants. In the course of the 16th century, the centre of Dutch culture moved to the northern Netherlands, especially to Holland. During the Eighty Years' War (1568–1648) the province of Holland formed the centre of the resistance against Spanish rule. The northern provinces rallied round Holland and, when free from the Spanish yoke, rose to great prosperity in the 17th century. The southern provinces remained in Spanish possession and fell into decay. French threatened to supersede the original language. The development of the language in the north was aided by the exodus to Holland of refugees from the provinces occupied by the Spanish. In the language of Holland this southern Dutch influence is distinctly noticeable. In the 16th century the inhabitants of Holland pronounced the words *bijten* (to bite), *vijs* (five), *huus* (house), *muus* (mouse), etc., still monophthongal. From the middle of the 16th century the southern Dutch diphthongization spread more and more and has now become general in the educated language of north and south, though the monophthongs still survive in numerous dialects. There still exists considerable difference between the colloquial and the written language of Holland. The more dignified, formal, official terms are originally southern Dutch, whereas colloquial speech has preserved the original linguistic forms. It is also because of this old southern influence that the written language of the north differs comparatively little from that of the south and the authorized version of the Bible, the *Statenbijbel* (executed at Dordrecht 1626–35), was written in a language coloured by certain southern characteristics.

The history of the Netherlands is distinctly reflected in the spread of the Dutch language and its dialects. The original language of the Belgian provinces West Flanders, East Flanders, Antwerp, Brabant and Limburg and of French Flanders is still characterized by a wealth of dialects as in the middle ages. The dialects of all these districts are generally grouped together under the name Flemish. In these Flemish districts the dialect is spoken by preference, although the written language is taught in the schools. By the side of it French has taken a prominent place from the time of the middle ages. In Brussels the language of the greater part of educated people is still chiefly French, although the position of the Flemish speaking intellectuals has become much stronger in the capital as well as all over Flanders. To an important extent the battle against the Frenchification of Flanders has been won. Before the law French and Flemish now have equal legal recognition.

The state of affairs in Holland is less complex. The name "Holland," which originally only referred to the present provinces of North and South Holland, is now also used at home and abroad to designate the whole kingdom of the Netherlands. As a consequence of the expansion of the province of Holland in the 16th and 17th centuries, the language of this province was gradually adopted as the language of daily intercourse by all the provinces grouped round Holland. Provincial dialects are still spoken, a peculiar position being occupied by Frisian in the province of Friesland, which is separated from the Dutch dialects proper by a sharp linguistic boundary line. The other dialects cannot be sharply differentiated. If we move eastward from the centre of culture, Amsterdam, an increasing "eastern" colour can be remarked in the dialects, as they merge imperceptibly into those of the Low German group, where, in the adjoining German districts, numerous Dutch influences are found.

DUTCH LITERATURE The oldest literary writings to be found in Netherlands or Dutch are the works of Heinrich von Veldeke, who lived near Maastricht in Limburg at the end of the 12th century. He wrote a life of St. Servatius the patron saint of the town, after a Latin original, and an *Enchiridion* (Aeneid) after the French *Roman d'Enéide*. He also wrote love songs which, like his *Enchiridion*, were translated into German and exercised a very considerable influence upon German poetry. But his influence on Middle Dutch literature was less considerable although it is probable that the mystic poets of the Netherlands, and in particular the poetess Hadewych, borrowed from him.

The Influence of France—The great efflorescence of Dutch literature occurred in the middle of the 13th century in Flanders and Brabant. Most of the works written there were translations from the French. This applies in particular to the romances of chivalry. The French originals of these romances came into existence at different periods, but their translations into Dutch belong more or less to one period. Among others there exist in Middle Dutch fragments of a translation of the *Chanson de Roland*, of a *Willem van Oringen*, a *Renout van Montalboen*, *De Lorenen*, *Aiol*, etc. All these are "Frankish" romances. To this section also belongs *Carol en Elegast*. It is almost certain that there was a French original of this remarkable work, but so far it has not been discovered.

In the section of Celtic romances there exists one, or rather a double romance by Jacob van Maerlant the *Historie van den Grail* ("History of the Grail") and *Merlijnus Boeck*. It is a translation, as regards the beginning, a rather abbreviated and free adaptation of the *Joseph d'Armathie* and the *Merlin* of Robert de Borron. These adaptations date from approximately 1261. In 1326 Lodewijk van Velthem added to this the translation of a much more extensive work called *Koning Artur's Boek* after *Le Livre du Roi Artur*. Maerlant also adapted a romance of Torec, while books about the adventures of Lancelot, Perceval and the death of Arthur have also come down to us.

Under the name *Roman van Lancelot* we possess a vast work of compilation in which a number of British stories have been put together, and which also contains the original Dutch romance of *Moriaen*. And there is the *Fergut*, which tells how a peasant lad was turned by love into a perfect knight.

The most important of the eastern romances is the adaptation of *Floris ende Blancefloer* by Diederik van Assenede. It is the story of the love of two children who are brought up together, one a heathen prince, the other the daughter of a Christian count. Another eastern romance is that of *Partenopous en Melior*, which describes the love of a young man for a mysterious beauty who proves to be the daughter of the emperor of Constantinople.

Religious Literature—Religious poetry occupies a prominent place in Middle Dutch literature. There exists among other poems a *Leven ons Heren* ("Life of Our Lord"), compiled from various sources, written between 1260 and 1270. Various lives of saints were also narrated in verse. We have a life of St. Lutgarde by Willem van Afflighem, and fragments of several other lives of saints.

The ecstatic mystical songs of the nun Hadewych, who also wrote visions and letters, are the most important, from the aesthetic point of view, of the 13th century religious poems. The 14th century saw the decay of the romance of chivalry, while, on the other hand, religious literature acquired still greater importance. From that period also date a few lives of saints which, however, have no great literary value. More importance must be ascribed to the poem about Theophilus and to the beautiful legend of *Beatrice*, which are poetic versions of *Exemplum* (models or examples) displaying the favours which the Virgin Mary is able

to obtain for those who serve her. The really significant religious literature of the period is the mystic prose, notably that of Jan van Leeuwen, the good look of Groenendael, and even more important, that of Jan van Ruysbroek prior of the monastery of Groenendael near Brussels (1293-1381). His principal work is *Die Christusheit der geesteliken brulocht*. In all these works the relations between God and the soul which love Him are described, and the ways in which one can turn to Him.

Maerlant's Significance—There further exists an interesting and original literature of the third estate in the middle age. Jacob van Maerlant is its first and principal representative. We have seen that he also produced romances of chivalry. In addition he wrote religious poetry. He was a Fleming by birth. His special significance lies in the fact that he translated the craving of the new bourgeoisie for useful reading. So he wrote the *Rijmbijbel* which is an adaptation of the *Historia Scolastica* of Petrus Comestor. With this work and with his *Smaete Franciscus* (Leven he had entered a new field. Five lyric poems, which were partly translated but also very probably original in parts belong to this section of his work. He wrote didactic poetry in the same very skilful strophic arrangement. There are two dialogues between Jacob (who represents Maerlant himself) and Martijn, about society and the church about the relations between social classes, love, God, sin and similar subjects. But there are also works on a larger scale and of more scientific content, written to instruct the *bourgeoisie*. His *Hemelrijcke der Hemelrijcke* ("Secret of Secrets") is a guide for princes. *Der Natueren Bloem* ("The Flower of Nature") is a moralizing handbook of natural history. These works are adaptations of Latin models. For us Maerlant is principally a source of information about his time rather than an artist. Nevertheless he proved himself a real poet. His original contributions in the sphere of didactic poetry found many imitators during the 14th century, among whom Boendale deserves special notice.

The mediaeval bestiary is represented by *Esopet*, a volume of fables after a Latin original (*Romulus*). But of much greater importance is *Van den Vos Ranaude*, one of the masterpieces of Dutch literature. It was a free translation from the French branch of the Reynard romance, *Le Plaid*, by one Aernout, made about 1250, while a certain Willem (who in the opinion of some literary historians must be considered the sole author of the Reynard), completed this adaptation with a piece about equal in length which described how Reynard succeeded in escaping the gallows by a series of extremely clever though false accusations, made at the court of King Nobél. The whole Dutch Reynard is a beautiful work, full of the most delicate popular humour and psychology.

Mediaeval Drama—Among what remains of the drama of the middle ages there are a number of religious plays and a quantity of very interesting secular plays, from which the religious element, however, is usually not lacking. The *Abele Spelen*, 16, serious secular plays, which have come down to us are *Esmeret*, *Gloriant* and *Lancelot van Denemarken*. Each *Abel Spel* was followed by a farce (*Sotturne*). Six *Sotturnen* are still known dating from the 13th century. They are pleasant pictures of daily life.

The mystery plays date from the 15th century. Seven such plays had been written about the seven joys of the Virgin, one of them being performed in each of seven successive years. There are still extant *Die Erste Biscap van Maria*, and *Die Sevente Biscap van Maria*. There also exists *Tyspel van de Vroede ende van de Dwase Maegden*, in which the wise and foolish virgins bear the names of different virtues and sins. This takes us far upon the way to allegory. Other plays, dating probably from a later period in the 15th century, are the two miracle plays *Van den Heylighen Sacramente van der Nyeuwaerwaert* by Smecken, and *Mariken van Nieuwmeegen*. The second, like the *Renwert* and a few of the mystical songs of the nun Hadewych and of Sister Bertke, a hermit of Utrecht, is one of the jewels of mediaeval Dutch literature. The later middle ages were characterized by the production of a considerable number of greatly varied popular songs many of which are very beautiful.

Chambers of Rhetoric—The 16th century was, in the prov-

inices of the Netherlands, the centre of the *Rechtspraak* is a name which is a popular rendering of rhetoricians or members of the chambers of rhetoric. These chambers were of much more in client date and their curious literature goes back to about 1300. They were societies of burghers who had to practice literature by recitations, the oral performance and even by poetic composition. In this domain also the southern Netherlands gave the lead. In the north the oldest chamber, Het Bloemken in Leiden, of Middleburg dates from 1350. A highly placed person usually acted as patron. The real ruler of the society was the factor, who often wrote the plays himself and produced them. These chambers really had a great significance in social history. If they diffused notions about poetry and its technique among the masses, they were also instrumental in spreading new ideas of every kind. They did not, however, produce anything of real artistic value.

In 1548 Matthias de Castelein compiled his *Const van Rhetoeriken*. It was an *ars poetica* for rhetoricians and placed the emphasis on the technique of poetry. The importance attached by the chambers of rhetoric to difficult forms and complicated rhyme arrangements gradually increased. Still real sentiment is expressed in three volumes of *Rechtspraak* by the Antwerp schoolmasters, Anna Bijns who proved her self ever militant servant of the old church in the fight against the dominant Lutheran doctrines. Most of the extant works by rhetoricians are allegorical plays, so called moralities or *Spelen om sinnen*. The morality *Elektrische* written at the end of the 15th century is unmistakably related to the English *Everyman*. It has not been definitely established which of the two is of earlier date. The medieval trace also persisted by the rhetoricians it was usually called *Esbattement*. There is a collection of 16th century plays which form the archives of the former chamber of rhetoric of Harlem called *Trou met bloemen*. This collection contains several such *Esbattements*. The principal poet of this genre is Cornelius Everaert of Brugge (1485-1556). To *Esbattement* as well as to allegory he made important and fine contributions.

The Early Renaissance—The effect of the Renaissance was noticeable. In this connection it is unnecessary to say much about the world famous Desiderius Erasmus of Rotterdam because he wrote exclusively in Latin. A few quite remarkable writers who belonged to the early Renaissance used the national language. The Brabander Jan van der Noot, who admired and translated the work of Pierre de Ronsard, and Carel van Mander, who also wrote an important book on painting (*Het Schilderboek*) there was also Jan van Hout, secretary to the town of Leyden. These men differ altogether from the rhetoricians who adorned their style with mythological names. They have communed with the pure spirit of the Renaissance through the poets of the French Pléiade. Greater however, was the effect of the Reformation, a movement which touched and agitated the whole of the population. The political and religious struggle against Spain is reflected in the so called *Geuzendichtjes* which tried to spur people on to action. Philip van Marnix van St. Aldegonde (1533-98) wrote the *Bun corf der Heilige Roomsche Kerke*, perhaps the bitterest satire ever written against the Catholic Church, which called forth a number of replies. The poet D. V. Coornhert (1522-90) occupied a peculiar neutral position between the warring factions, which duly persecuted him each in its turn. His principal work is the *Zedekunst, dat is Wellevenskunst*.

Meanwhile in Amsterdam the chamber of rhetoric De Eglantier was flourishing as a centre of literary culture. Its motto was "In liefde bloeyende" (i.e., "flourishing in love"). During the latter part of the 16th century and the beginning of the 17th one of the principal members of this chamber was the humanist Hendrik Laurenszoon Spiegelius (1549-1611) whose principal work was the *Heitspiegel*, a rather laborately composed poem, which expounded a doctrine not unlike that of Coornhert. Another important member was Roemer Visser, who wrote familiar and comical little rhymes (*Brabbeling*) and also wrote little mottoes in prose to accompany printed pictures (*Sinnepoppen*).

The Golden Century—The chamber De Eglantier also made great efforts to refine the national language, to polish it and to free it from French bastard words. In 1584 it published a *Twee-*

spiegel van de Nederduitsche letterkunst, a Renaissance grammar with important practice by Coornhert. A factor of the greatest significance in the development of the civilization and culture of the Netherlands was the emigration of Calvinists from the southern Netherlands.

The principal poets and prose writers of the golden century are J. J. Cats (1577-1666), Pieter Corneliszoon Hooft (1581-1647), Gerbrand Adriaanszoon Brederode (1585-1618), Joost van den Vondel (1587-1679) and Constantijn Huygens (1596-1687).

J. J. Cats, born at Brouwershaven, studied at Leyden and at Orléans. He became advocate of the town of Middelburg (1603), made a fortune by reclaiming land from the sea, successively occupied the position of pensionary of Middelburg (1621) and of Dordrecht (1623). From 1636 to 1651 he was pensionary of Holland after which he retired to his country house Zorghvliet near The Hague. His work is worthy but easy to understand, and during the whole of the 17th and 18th centuries it was read by the people and had its place beside the Bible. It is a treasure house of moral precepts and practical worldly wisdom. His principal works are *Hoofwielijk* (1605), *Spiegel van den ouden ende nieuwen Tijd* (1631), *Trou Rijn*, *h* (1637) and *Ouderdom, Buytenleven en Hoofwielijk op Zorghvliet* (1655). Cats was only a mediocre poet, but culturally his significance has been immense. He is the representative of the ideas of the Calvinist masses.

Constantijn Huygens was born at The Hague. In 1616 and 1617 he studied law at Leyden and travelled several times as secretary of embassy (he made three journeys to England). In 1625 he became secretary to the stadholder Frederick Henry, afterwards to Prince William II and finally to Prince William III. He considered his professional work to be the principal part of his existence and his poems were "flowers in his cornfield." He had little fantasy and in his work mainly depicted himself and his surroundings. His principal works in Dutch—for he also wrote in Latin—are *Voorkout* (1621), a description of the well known promenade at The Hague, *'t Costelick Mal* (1622), a satire on eccentric fashions, *Dagwerck* (1639), a description of the manner in which he spends his day, *Oogenroost*, a poem in which he tried to console his blind friend Lucretia van Trello by explaining how nearly all people go through life blinded by their passions, *Hofwijck* (1653), a description of his little country home, *Zeestraat* (1666), which describes the road made after his plan between The Hague and Scheveningen. There is also a play called *Tijntje Cornelis* and an autobiography of his later years, *Chuywerck* (1680) which was only published in the 19th century.

The Influence of Amsterdam—We now pass to Amsterdam. There at the beginning of the 17th century, two chambers of rhetoric were flourishing, De Eglantier, already mentioned, and 't Wit Lavendel, which was the Brabant chamber where refugees from the southern Netherlands came together. Differences of opinion made themselves felt in the Eglantier. Many of the best members in whose view the practice of rhetoric did not mainly consist in pleasant gatherings, seceded in 1617. Among their number were Hooft and Brederode. Under the direction of Samuel Coster, a medical man who also wrote, they founded the *Duytsche Academie* which aimed at giving instruction, after some time, however, the activities of the new chamber were limited to the production of plays. In 1635 the old Eglantier and 't Wit Lavendel (united since 1623) amalgamated with the seceders and the result was the foundation of the *Amsterdamsche Schouwburg* (Amsterdam theatre) in 1637.

One of the most talented writers in this circle was G. A. Brederode, who was in exception among the great authors of his day in that he had received no classical education. His voluminous lyrical poetry has been collected in his *Boertigh, Amouren en Aendachtigh Groot Liedboek*. The first part of the book contains comical poems, little sketches of popular life, representing in the sphere of literature those things which in painting characterized the work of Jan Steen, Brouwer and Ostade. The amorous poems of the volume are in the vein fashionable at the time. As a dramatic author Brederode wrote in the first place romantic plays, the subject matter of which came from Spanish romances of chivalry. The comical interludes in these plays, full of popular realism, showed

a talent for comedy which reached its full height in his farces *Klucht van de Koe* (1611-), *Klucht van Symen vande Soetcheit* (1612-13) *Klucht van den Molenaar* (1613), and also in his two comedies, *Het Mooitje* (1615) and *De Spaansche Brabander* (1617). The first was based on the *Eunuch* of Terence, the second was after *Lazarillo de Tormes*. The local colour in both plays was entirely derived from Amsterdam.

Another lyric poet and playwright whose gifts were more modest, but who was decidedly related to Bredero was the adventurous wanderer Jan Starter (1594-1628), born in England, who was a member of the Eglantier at the same time as Biedero. He founded a chamber of rhetoric at Leeuwarden, later went to Germany where he became the historian of the count of Hansfelt. His poetry has been collected in the volume *De Friesche Lusthof* (1621).

Pieter Hooft is the most typical representative of the Renaissance in the literature of the Netherlands. His art is personal and refined. He came from an Amsterdam merchant family, was destined for commerce and was sent on a commercial journey to Italy (1598-1601). The love poems which he wrote after his return and the pastoral play *Grandia* (1605) show the influence of the Italian Renaissance. In 1606 he was allowed to study law at Leyden. When his studies were finished he was appointed *drost* of Muiden. In this position he lived in the famous Muiderslot or castle of Muiden. Inspired by the place in which he was living and also strongly influenced by the tragedies of Seneca, he wrote in 1612 *Geeraard van Velsen* and in 1625 *Baeto*. In both plays he has expressed his political ideas in a very anachronistic manner. He also adapted Plautus' *Aulularia* into a comedy of Amsterdam called *Ware nar* (1616). Particularly after 1627 his home became the centre of artistic and intellectual life, formed by the Muderkring (circle of Muiden). During the last 20 years of his life, he devoted himself almost exclusively to historical prose. In 1626 he wrote *Hendrik de Grote*, in 1628-47, *Nederlandsche Historien*, which he left unfinished. The artistic prose of these writings, strongly influenced by Latin, exercised a great influence on the literary prose style of the 17th century.

The Genius of Vondel.—Joost van den Vondel is the greatest poet of the golden century in Holland. He was born in Cologne of parents who came from Antwerp, whence they had fled as Anabaptist refugees. When Joost was still very young his parents migrated to Amsterdam. There he had a hosiery shop in the Warmoesstraat, but his wife Maaken de Wolf managed the business and allowed her husband to give all his time to study and art. He was a real product of the Renaissance, full of veneration for the ancients whom he tried to imitate, particularly in his tragedies.

Vondel's work is voluminous. There are in the first place the satirical poems occasioned by the religious and political struggles between Arminians and Gomarists. His tragedy *Palamedes* (1625) represents the struggle between Prince Maurice and Oldenbarneveldt in an allegorical form and belongs to his satirical work. There are further *Roskam*, which criticizes the abuses of the government of the regents, and *Harpoen*, which compares the good and the bad minister. We may mention, among his songs celebrating the national greatness of the Dutch republic, the glory of the house of Orange and of Amsterdam, *Lof der Zeevoert* (1622), *Geboorteklok van Willem van Nassau* (1625), *Inwijding van het Stadhuis* (1655). Of great beauty are the intimate lyrical songs of moving simplicity which Vondel wrote after the death of close members of his family. After he had become a Catholic he wrote three long poems in defense of his faith: *Altaergehemissen* (1645), *Bespiegelingen van Godt en Godsdienst* (1662), *Heerlyckheit der kerke* (1663). But the principal work of Vondel consisted of 24 original dramas. The first was *Psuscha of de Uyttocht der Kinderen Israels uit Egypte*. Among his other dramas are *Gysbrecht van Aemstel* (1637), *Maeghden* (1639), a dramatic version of an episode of the life of St. Ursula, *Joseph in Dothan* (1640), *Maria Stuart* (1646), *De Leeuwendaers* (1648), a play written on the occasion of the peace of Munster. His masterpiece was *Lucifer* (1654), describing the revolt of the angels against God. *Jephtha* (1659) and *Adam in Ballingschap* (1664) are other plays of his.

Three religious poets from the great period of the 17th century deserve separate notice. The first is Johannes Stalpert van der Wiele, parish priest at Delft (1570-1630), whose life of St. Agnes and *Geschiedelike Lofzangen*, imbued with a true medieval spirit are his best known works. Jacobus Reijns or Reijns (1586-1658), was a Protestant minister of Deventer (*Overyselsche Zangen en Dichten*, 1630) and D. R. Camphuisen (1586-1627) wrote *Sichtelijke Rymen*.

The Late 17th Century.—Later in the 17th century comes Jan Vos whose rhetorical pieces *Arian en Titus* (1641) and *M. dea* (1666) were produced with elaborate stage machinery which made quite a sensation. Gerard Brandt (1626-85) was a prose author who wrote *Historie der Reformatie*, *Leven van Adr. d. Ruyter*, *Leven van P. C. Hooft*, *Leven van Vondel*. Heiman Dullaert (1636-84) was a painter, pupil of Rembrandt, who wrote a few poems full of true sentiment which were among the best of his time.

The last generation of the 17th century is represented by the following writers: J. A. van der Goes (1647-84) was an imitator of Vondel. His principal work was *De Ystroom*. His language has something of the ease and grace of Vondel's but rather lacks simplicity. Jan Luiken (1649-1711), a world famous etcher and engraver, ranks as a poet near to Hooft and Vondel. The work of his youth was *De Duitse Lien*, a volume of love and nature poems. When he was 26 he became converted to a mystic and ascetic conception of life. Henceforth he only wrote pious verses, of which the best is the first, *Jesus en de Ziel*. Thomas Asselyn and Pieter Bernigie wrote comedies. The first is known mainly for his play *Jan Klaess of de gewoende Dienstmaegd*, in which he makes fun of the Quakers.

The decadence which had already set in by the end of the 17th century became accentuated in the 18th. The so called *Pruken-tijd* or "period of wigs" was a time of great wealth, when people were seized with a mania for collecting and the art of poetry was practised in an amateurish way. Written in a form that was bound by the strictest rules, it was nothing but servile imitation of French models. The best known among the societies where that kind of poetry was practised, the *Nil Volentibus Arduum*, was established at Amsterdam in 1669. One of its leading members was Andries Pels, who published in 1677 an *ars poetica*.

Early 18th Century Prose.—The three principal authors of the first half of the 18th century are Pieter Langendijk (1683-1756), known to our own day as an author of comedies which are still performed, the moralist Justus van Effen (1684-1735) and the peasant poet Hubert Poot.

The principal works of Langendijk were *Het Wederzijds Huwelijks Bedrog* (1712-14), *Kretis Louwen of Alexander de Groote op het Poetemaal* (1715) and *De Wiskunstenaars of 't Gevulchte Juffertje* (1715). He is an imitator of Molière, and in the polish of his smooth alexandrines shows himself a real man of the 18th century. Justus van Effen was mainly the author of moralizing works, some of which were written in French. He followed the example of the English reviews, *The Tatler* and *The Spectator*, and applied their methods also when later in life (1731-35) he published *De Hollandsche Spectator*. Between 1741 and 1800 at least 30 weekly papers of the same kind appeared. The best known are *De Denker* and *De Gyzardaard*. These *Spectatoriale vertoogen* had a great influence on the Dutch *Verlichting*.

Some further typical representatives of the period are Hoogvliet, author of *Abraham de Aartsnyder*, Sijbrand Petrama, translator of the *Télémaque* of Fénelon and of the *Henriade* of Voltaire, Balthazar Huydecoper, a philologist and author of tragedies in the style of the French classics. The two Friesian noblemen, Willem and Onno Zwier van Haren, have a certain imaginative originality and are remarkable for the choice of national subjects for their poetry.

English Influence on the Novel.—In the last quarter of the 18th century started the movement of *Verlichting*. Classicism, which had gradually become a rigid and soulless form, was the special butt of the critics. The "enlightened" Elizabeth (Wolff) Bekker (1738-1804) and her friend Agathe Deken (1741-1804), who started by being more piously inclined, joined forces after

they had for some time been publishing independently. Their collaboration produced some novels in letter form. Of these the first is a *Sara Barckhaert* (1783) and *Willem Leend* (1783-85) are the more important. In construction and in form they belong entirely to the school of Richardson. They are remarkable for their ease and fluidity of expression.

Rhijn is both (1783-85) is in an entirely different type a sentimentalist strongly influenced by Young. D. Arnold Klopstock and especially Goethe's *Werther*. He wrote a few sentimental novels, *Julia* (1783) and *Leendardine en Constant* (1784). Later in life he wrote didactic poems (e.g. *De Ouderdom*, 1803) and many songs which are still used in church hymns. He also had a certain significance as a writer on aesthetics, but in that sphere he was less important than Hieronymus van Alphen (1740-1803), who translated Rieck's *Theory of Fine Arts* and provided it with an important introduction. He is now better known as the author of children's poems. Another poet of a very patriotic was Jacobus Bellamy (1787-80). His style was rather bombastic.

Bilderdijk—Willem Bilderdijk (1766-1837) is a great figure who exercised considerable influence upon the spiritual life of Holland. He was an Organist in opposition of the party of the Patriots. In 1795 he refused to take the oath of allegiance to the government of the Batavian republic which had been established by the French and received the unwelcome exile penalty of exile. He roamed about Hamburg and London where he fell in love with Katharina Wilhelmina Schwieckhardt, who later became his second wife. When Louis Napoleon became king of Holland, Bilderdijk was recalled to Holland and treated with much consideration. After the restoration King Willem I gave him a pension. He was not appointed a professor of Leiden as he had hoped to be but established himself in that town as a private tutor (1812-17) and had a number of very able students who attended his courses in national history, venerated him as a prophet and adopted a considerable part of his political and religious views. The movement which aimed at propagating these religious ideas was called the *Revol*.

Bilderdijk wrote ballads and longer narrative poems such as *Thuis en Verre en's alenijm*. The epic *De Oorlog van de Eerste Wereld* (1820), which he left unfinished, contains beautiful passages. The immense bulk of his lyric poetry contains some expressive poems especially among his love songs and others full of very deeply felt religious emotion such as *Gebied* (1796) and *Boetsang* (1826). Among the longer poems the *Ode Van Napoleon* (1806) and *Utscheid* (1810) are celebrated. His *Geschiedenis des Vaderlands* contains part of an autobiography.

Johannes Kinker (1764-1843) was also a critic, a philosopher and a philologist. He criticized the insignificance of his conventional and sentimental contemporaries. Among the numerous but insignificant writers of the French period mention may be made of Adriaan Louvoys, whose *Maurits Layslager* is a forerunner of the historical novel and Jan Frederik Helmers (1767-1813) who published his bombastic but deeply patriotic poem *De Hollandse Natie* in 1812 during the French domination.

The 19th Century—The first part of the 19th century was less distinguished even than the revolutionary period. It was a time of rhetorical self-complacency. The orator Henricus van der Palm (1793-1841), whose *Geschied en Redekunstig Gedenkschrift van Nederlands Hervorming* (1816) is the best-known work re-established formalism after the laxity of the revolutionary period. The typical representative in Holland of familiar fireside poetry was Hendrik Tollens (1790-1856). During that period we may notice Bilderdijk's ardent admirer and disciple Isaak da Costa (1798-1860). Da Costa's main work, directed against Liberalism, was *Beswaren tegen den Geest der Eeuw* (1823). Among his poetic works the best known are his *Tijdszangen*, which Da Costa himself called his political poetry. His biblical poem *Heugl* (1847) had a symbolical meaning. Islam will one day bend the knee before Christ. In 1837 he wrote a historical poem *De Slag bij Nieuwpoort*.

Antonie Christiaan Wymand (1767-1840), an excellent poet who stood almost entirely by himself, was a gentleman farmer of Gelderland. Apart from many lyric poems and some epigrams

(*Sneelichting*) he wrote a few fine stories in verse *De Twee Bultmanns* the cycle of *Jaromir Marco De Hoofdighe Boer*, *De Leerdine van Paulvates De Verjongingsluur*.

Jacob Giel (1789-1863), excellent prose writer, became librarian of Leiden university in 1822 and afterward a professor. His main work consists of a series of treatises and essays, of which the eight principal ones have been brought together in one volume, *Onderzoek in Phantasie*. One of them, *Geschied op den Drakenfels* (1835) attempts a just appreciation of romanticism, which had made its way into Holland about that period. Jacob van Lennep (1802-68) and Jan Frederik Oltmans (1806-54) are gifted followers of Scott but their subject matter was national. Van Lennep wrote poetic stories, a few plays, but mainly historical novels and short stories which gave him considerable popularity. He started with medieval stories *De Pleegzoon*, *De Roos van Delam*, *Oude Tonsuuriers*. His later novels *Ferdinand Huyck* and *Lizabeth March*, written under the influence of *De Gids* (about which more presently) describe the period of the Dutch republic. Van Lennep is easy and entertaining but superficial. Under the influence of French nationalism, he also wrote a contemporary novel called *Klaasje Zilverster*. Under the pseudonym J. van den Hage, Oltmans wrote two novels *Het Slot Loevestein* and *De Schaapshoeder*.

Another important figure in the Romantic movement is Anna Louisa Gertruida Bosboom-Toussaint (1817-86), who, like Nikolaas Beets, began to write under the influence of the English romantics (*Imago*, *De Graaf van Devonshire*). The criticism of *De Gids* made her choose national subjects. She wrote in praise of the heroes of Protestantism during the 80 years' war against Spain. Her best known works are *Het Huis Launessens* (1840), the cycle about Leicester in ten volumes (1846-55) and *De Dichters*, *De onderdokter*. Like Van Lennep she deserted the historical novel during her later period and wrote a novel in the form of a diary entitled *Major Frans* (1875).

National Consciousness—Typical of the romantic movement in Holland was the periodical *De Gids*. The critic and author Aernout Drost, who died young, started a review in 1834, called *De Muzen*, which had only a short existence. Everhardus Johannes Potgieter followed him in 1837 with *De Gids*; in which he tried to strengthen the national consciousness of his compatriots. He was haunted by the ideal of national strength, represented by the grandeur of the 17th century. From 1837 to 1865 he directed *De Gids*, contributing to it a number of important criticisms and many sketches, the most characteristic of which is *Jan, Janneke, en hun jongste Kind* (1842), where he contrasts the past and present of Holland. In *Het Rijksmuseum* (1844) he extolled the Holland of the 17th century. Potgieter's style is difficult and full of learned allusions. Especially important are his later long stories (*Onderweg in de Regen*) and the imaginative poetry of his mature years (*Gedroomd Paardrijden in de Nalaten schap van den Landjonker*, 1875). Before he died Potgieter had come to despair of the success of his enterprise, and among the younger men he could discover no one whom he judged able to take over his task. The learned historian (later archivist) Reinier Bakhuizen van den Brink (1810-65), mainly known through his studies of the 17th century, published in *De Gids*, was a kindred spirit.

In the Dutch literature of that period a very peculiar place is occupied by Nikolaas Beets (1814-1903). During his student days he was an enthusiastic admirer of the English and French romantics. Under the influence more particularly of Byron, he wrote four stories in verse. But he owes his fame entirely to *Camera Obscura* a book which has become a classic. It consists of a number of sketches which give a delicately humorous picture of the middle class society of his day. Beets also wrote many poems, most of which are in the manner of Tollens.

Pieter Hasebroeck (1812-96) was, like Beets, a Protestant minister. His volume *Waarheid en Droomen*, published under the pseudonym of Jonathan, somewhat resembles the *Camera Obscura*. A similar resemblance appears in the sketches of student life by Johannes Kneppelhout, who wrote under the pseudonym Kikspaan (1814-85).

There is also a Catholic romantic, Josephus Albertus Alberdingk Thym (1820-89). Like Potgieter he loved the Amsterdam of the 17th century, but his description of that period is mainly restricted to Catholic circles. The modernist Protestant minister Petrus Augustus de Genestet (1829-61) was a popular poet and also wrote a series of *Leekedichtjes* (lay poems) about the religious struggle between the orthodox and the modernists.

(J. WAL, X)

Carel Vosmaer (1826-88) who edited *De Nederlandsche Spectator* and translated Homer should be mentioned as a critic who appreciated the real importance of the writers who heralded the renaissance of Dutch literature at the end of the 19th century.

Conrad Busken Huet (1826-86), of French descent, was especially important as a witty and sharp critic. In his influential critical work, collected in 25 volumes, *Literaire Fantasmen en Kritieken* (1868 and following years), he adopted the critical method of C. A. Sainte Beuve. After working in the Netherlands East Indies as a journalist he spent the last part of his life in Paris. Important as well is his history of the Dutch 17th century cultural life, *Het Land van Rembrandt* (1882-84).

Edward Douwes Dekker (1820-87), who because of his great gifts as a prose writer and his easy natural style was a forerunner of the revolutionary literary movement of 1880, wrote under the pseudonym of Multatuli his *Max Havelaar* (1860), a glowing and moving protest against the treatment of the Javanese by the Dutch authorities. Douwes Dekker had been an official in the Netherlands Indies. The book created an immense sensation and contributed greatly to the later improvement of conditions in the Dutch colonial possessions.

In 1861 Multatuli published a remarkable collection of intimate essays in the form of letters, *Minnebrieven*, followed between 1862 and 1877 by seven volumes of *Ideeen*, brilliant polemical notes about the fossilized aspects of the Dutch 19th century life, which contain his beautiful unfinished novel *Wouterje Pieterse*. Multatuli is the undoubted genius of Dutch 19th century letters but because of the fearless nature of his writings and his irregular private life he remained a controversial figure who with equally great heat of passion is censured in some quarters and venerated in others.

In the Flemish part of Belgium, where in the course of the several successive foreign dominations popular education had been stagnant, a new movement arose after 1830, the Flemish movement, of which the novelist Hendrik Conscience (1812-83), who taught the Flemish people once more to read and use their own language, was for some time the best-known literary representative. Conscience celebrated the grandeur of the past of Flanders. His best known novels are *De Leeuw van Vlaanderen*, *Jacob van Artevelde*, *De Loteling*. Among the poets of the movement the foremost is Guido Gezelle (1830-99), whose poetry in which he glorified God and nature is of the greatest importance because of his unorthodox, free and inspired use of the language. His most beautiful poetry is found in *Tyckdrans* (1893) and *Rijmsnoer* (1897).

Renaissance of the 1880s—In the northern Netherlands an important renaissance of literature took place about 1885. It is usually considered to have started in Oct. 1885 with the publication of the first number of the review *De Nieuwe Gids*. The forerunners of this movement were Dekker, the novelist and poet Marcellus Emants and the delicate lyric poet Jacques Perk (1859-81). The *Nieuwe Gids* differed from *De Gids* in that it pursued an exclusively aesthetic ideal. The leaders of the movement were the poets Willem Kloos (1859-1938), Albert Verwey (1865-1937) and Lodewijk van Deyssel, the pseudonym of Karel Alberdingk Thym (1864-1952). Kloos sang the beauty that pleases the senses. Verwey passed from impressionist to symbolical verse. He also did good work in literary history (among other works he wrote a book about Potgieter). Van Deyssel was the violent and lyrical critic of the movement. Frederik van Eeden (1860-1932), dramatist, poet and prose writer, occupied a special place. His best work in prose is *De Kleine Johannes*, the story of the soul of a child. His *Van de Koel Meren des Doods* is an important pathological novel. Van Eeden also took part in an experiment at

communistic life which proved a failure. His plays are hardly the expression of his social feelings and opinions. The poetess Helena Lapidoz Spruth (1850-1912) stood very near to the movement with her lyrical works written in particularly delicate language full of resonance. Herman Gorter (1864-1927) acquired a foremost position in Dutch poetry by his poem *Mei*. Jan Hendrik Leopold (1865-1915), poet of a tragic individualism, produced work of great sensitivity. Peter Cornelius Boutens (1870-1943) gradually obtained a mastery of his poetic form and expressed himself in strongly rhythmic verse, sometimes of an unearthly beauty.

Among the men of the 1880s (*De Tachtigers*) we must also place Jacobus van Looy (1855-1930), a writer of beautiful prose (*Proza Gekken Feesten*, *Jaapje*, *Jaap*, the last two of which are autobiographical). The great novelist Louis Couperus (1863-1923) described the life of The Hague (*Elsje Verre*, *De Boeken der Kleine Elsje*) and made splendid imaginative reconstructions of antiquity (*De Berg van Licht*, *Antich Torisime*, *Ilirables*, *De Komendanten*, *Iskander*). The movement of the 1880s was mainly individualistic. Immediately afterward came a group of authors whose feelings were more social. The dramatist and writer of sketches, Herman Heyermans (1864-1924), wrote social dramas which are among the greater triumphs of the Dutch stage (*Ghetto*, *Het Zesde Gebod*, *Op Hoer van Zee*, *Ordi et labora*, *Allezvleis*, *De Openende Zon*, *Schakels*, etc.). The novelist Israel Querido (1872-1931) was a typical Dutch naturalist (*Levensgang*, *Menschenwee* and the cycle *De Jordaan* in four volumes). In addition we mention the novelists Carel and Marjo Scharten-Antink (*Een Huis vol Menschen*, *De Vriende Heerschers*, *'t Geluk Hangt als een Draventrout*) and some women novelists, A. G. van Nieuwen (Orpheus in de Dresse), Ida Boudier Bakker, Top Naeff and Carry van Brugeen.

20th Century Writers—After the intoxication of the soul and the senses in the revival of the 1880s most of the writers of the early 20th century had turned away from this pronounced individualism in a socialistic or ethical direction. The language became sober once more. In prose, reasonableness and wisdom were stressed more than beauty and colour. This sentiment found expression in Albert Verwey's magazine *De Beweging* (1905-19). Another important reaction to the 1880s was that of the idealistic pioneer socialists like Herman Gorter and the powerful lyrical poet Henriette Roland Holst (1869-1952).

Some of the most significant contemporary poets are Adrian Roland Holst (1868-52), who is withdrawn like W. B. Yeats in his own mythological world, J. C. Bloem (1887-52), who writes a poetry of longing and disillusion, P. N. van Eyck (1887-1954), poet and essayist, Martinus Nijhoff (1894-1953), whose work seems to catch the crystal clear morning light of a Dutch interior by Vermeer, Victor Emmanuel van Vriesland (1892-52), erudite essayist and poet steeped in the French symbolist tradition. The principal prose writer of the period of neoromanticism is Arthur van Schender (1874-1946), who in his most mature writing created the same scene, and especially moral world found in Rembrandt's paintings. Aart van der Leeuw (1876-1931) was a subtle poet and prose writer of an idyllic romanticism. Antonie Donker (1892-52) writes a reflective verse of a melancholic nature.

World War I produced three great poets, Jan Slauerhoff (1898-1936), Hendrik de Vries (1896-52) and especially Hendrik Marsman (1899-1940) who, under the influence of German impressionism, attempted to break with all tradition. Jan Greshoff (1888-52), poet and essayist, has his proper place among the younger generation group around the literary magazine *Forum*, established in 1932 by Menno ter Braak (1902-1940)—a brilliant cultural philosopher and independent thinker, and Edouard du Perron (1900-40), eminent polemical essayist and novelist of great force, leaders of a movement of writers who wanted in literature less surface, fewer beautiful words and greater sincerity.

Between World Wars I and II, a period of anxiety and mental stress, the influence of Sigmund Freud became strongly marked in irrational poets such as Gerrit Achterberg (1905-52) and Eduard Hoornik (1910-52) but was most clearly noticeable in the prose, poetry and essays of the most important and prolific contemporary Dutch writer, Simon Vestdijk (1907-52), who, as a subtle psychologist like Thomas Mann, owes a great deal to the clever manipulation of Freud's anthropological theories and to the projection of the various states of consciousness in the manner of James Joyce. The main theme of the novels and short stories of Frans Bordewijk (1884-52) is the search for an equilibrium between chaotic fear and severe discipline. After the wartime period of occupation, which influenced Dutch literature deeply, and the liberation of 1945 new groups of writers, either in an experimental or existentialist vein, came to the fore.

Contemporary Flanders has occupied an important place in modern Dutch literature since the foundation of the literary magazine *Van Nu en Straks* at the end of the 19th century, which introduced a similar literary revival as in the Netherlands proper. Among the foremost writers are the novelists Stijn Streuvels (1871-52) and Cyriel Buysse (1859-1932), the classicist and imaginative poet Karel van de Woestijne (1878-1929), Herman Terlinck (1879-52), novelist and dramatist, who produced his major novel *Het gevecht met de Engel* at the age of 17, Jan van Nijlen (1884-52), a poet of the wisdom of the heart, Maxam Guisen (1891-52), a highly accomplished moralistic prose writer, Raymond Brulez (1891-52), a delightful novelist with a philosophical turn of mind, Willem Elsschot

(1882—) satirized mercilessly the huckstering methods in advertising in his own novel *Tippen* (1907). Gerard Wilschup (1898—) is a masterly psychological observer of the pathological aspects of Finnish rural life. Maurice Rodtius (1895—) introduced into Flemish letters the psychological novel of Gille eluitt.

DUTCHMAN'S BREECHES (*Dicentra Cucullaria*), 2

North American plant of the fumitory family (*Lamiales*), known also by various local names, as butterfly banner, boys and girls' car drops and soldier's cap native to woods from Nova Scotia to South Dakota and southward to North Carolina and Kansas. It is a smooth, delicate plant, rising from a granulated bulb, with the slender stalks, finely dissected leaves appearing to spring from the surface of the ground. In shape the irregular flowers, about $\frac{1}{2}$ in broad, resemble a pair of baggy trousers, whence the popular name. The flowers are white or pinkish, tipped with yellow, and hang tremulously from a slender stalk, 5 in. to 10 in. long. This plant, which blossoms abundantly in early spring is one of the most dainty of North American wild flowers. (See *DICENTRA*.)

BY COURTESY OF THE WILD FLOWER PRESERVATION SOCIETY
DUTCHMAN'S BREECHES, AN EARLY SPRING FLOWER IN NORTHERN AND EASTERN UNITED STATES

DUTCH METAL A variety of brass, in which the proportion of zinc is high, giving the alloy a yellow colour, simulating gold. The proportions of copper and zinc in Dutch metal range from 88 to 85 to 15, the colour becoming paler with the higher zinc content. Dutch metal is used in bronzes, and in the preparation of imitation gold leaf, as its ductility lending itself to the purpose. Gilding with Dutch metal costs less than one third the price of real gilding, but the work rapidly tarnishes unless coated with a lacquer. (See *BRASS*.)

DUTCH OVEN This utensil is in general use in American colonial days for baking before the open fire, which was the only means of cooking except the brick oven (*qv*). It was round, square or oblong, with the front open. The round variety was often fitted with a spit, turned by a handle on the outside, for roasting meat. Otherwise, the oven was used for baking only. The open side was set close to the fire, to receive the full heat of flames or coals. Usually of tin, it was often called "tin kitchen" or "Dutch kitchen." The bake kettle—a covered receptacle on high legs to set over the fire—was sometimes called a Dutch oven.

DUTCH WARS, a general title for the three naval wars fought between England and the United Provinces (1652—74), but also for the almost continuous series of land campaigns fought by the Dutch against Louis XIV. (1667—78).

NAVAL OPERATIONS

First Dutch War (1652—54)—The immediate causes of the war were the continuous diplomatic rebuffs given by the Dutch to the English Commonwealth government. The real and underlying cause, however, was the commercial rivalry of the two nations, especially in the North Sea and Spitzbergen fisheries and in the East Indian trade while in addition the English disputed the Dutch claim to make their neutral flag cover goods consigned to France with whom England was already unofficially at war. (See *HOLLAND* *History* *ENGLISH HISTORY* *SHIPPING*,

HISTORY of, NAVIGATION LAWS, etc.)

Despite the great maritime strength of the Dutch, which had developed unchecked for nearly fifty years, England began the war with three overwhelming advantages. Geographically, she dominated the Dutch trade route passing through the Straits of Dover, her navy was directed by a single and united body, the Council of State, whereas the Dutch relied on the sporadic co-operation of five different provincial admiralties, finally, the Commonwealth government was prepared to lavish huge capital sums on the war, seized from the Royalists, while the Dutch were compelled to finance the war from an income largely derived from their threatened carrying trade and fisheries.

In the spring of 1652 Admiral Martin Tromp (*qv*) took a strong Dutch fleet into the Channel to protect the returning trade. The Dutch country was anxious to appear as the aggressor, but a collision occurred with Admiral Robert Blake's squadron on May 19 off Dover on Blake making the claim to the salute, some Dutch ships having been attacked further down the Channel for the same cause. Admiral Bourne came up later with a squadron from the Downs to assist Blake, and Tromp was eventually driven over to the French coast with the loss of two ships.

Blake was now ordered north to destroy the Dutch herring fisheries, which he succeeded in doing, also it possible to intercept the Dutch East Indiamen, said to be returning by the north of Scotland, and to harry their Baltic trade. Meanwhile Tromp and later on de Ruyter (*qv*) had matters their own way in the Channel against Sir George Aspinwall who had only 14 ships, the remainder being with Blake. As soon as the Dutch understood this, Tromp was ordered north to engage Blake. He sighted his adversary, but a storm scattered his fleet off the Shetlands, and in returning home he was superseded by Cornelius de Witt (*qv*) as a result of the outcry caused by the loss of the herring. In September de Witt concentrated his force, as did Blake, each having over 60 sail, and an action was fought on Sept. 28, when the English admiral cleverly neutralized de Witt's attempt to exploit the leeward side of the Kentish Knock as a defended anchorage. The Dutch were severely handled, while many of their captains refused action towards the close, being jealous of de Witt on personal and political grounds.

Tromp was now reinstated in command by the States General with over 80 ships, and ordered to force the outgoing convoy through the Channel, but the English Council of State, thinking that the season for active operations was passed, reduced the fleet considerably, and when Tromp appeared off the Goodwins on Nov. 29 Blake had only 40 ships ready in the Downs, many of them being only hired merchantmen. However, he determined to attack, and on Nov. 30 both fleets were clear of the Goodwins on parallel courses. Off Dungeness a general action was fought in the late winter afternoon, in which Tromp was successful, his convoy passing down mid channel without loss.

An immediate naval reorganization followed this set-back. The Council of State ordered several captains to be tried for unsatisfactory conduct and issued articles of war by which all captains of merchant ships engaged on government service were in future to be entirely under government discipline. The seamen's pay was increased, the victualling improved, and the command was strengthened by the addition of the generals George Monk (*qv*) and Richard Deane for service at sea.

Early in Feb. 1653 Blake took his fleet of about 70 sail down channel to intercept Tromp, who was known to be attempting to conduct the home bound Dutch convoy of merchantmen through the Channel. Thick fog made reconnaissance difficult, and the English fleet was somewhat scattered when Tromp suddenly appeared off Portland on Feb. 18 with about 80 sail, the wind being north-west. Blake's squadron having become separated had to withstand the whole of the Dutch fleet alone for some hours, till at last help arrived, when Tromp drew off to rejoin his convoy which had meanwhile slipped by unmolested. Next day, Blake pressed the Dutch vigorously and a running fight took place past the Isle of Wight, Tromp forming his fleet in a crescent to protect his convoy which sailed the 19. On Feb. 20, both fleets were off Beachy Head, and Blake again attacked, the English frigates

pressed through to the convoy, which became seriously disorganized, so that night alone saved them from disaster. It seemed impossible for the Dutch to round Cape Gris Nez, but Tromp managed to get the remainder of his fleet and convoy clear away before next morning, after a total loss of 17 men of war and over 50 merchantmen.

Both countries were now feeling the strain of the war, and for some time administrative and financial difficulties incapacitated their fleets, though Tromp was active in protecting convoys coming round the north of Scotland. Blake had been wounded off Portland, and upon Deane and Monk at last getting to sea in force, Tromp at once sought action, and on June 2 and 3 there was heavy fighting, beginning off the Gabbard and ending near the Dutch coast. For the first time the English fleet showed a decided superiority, recent fighting instructions having strictly enjoined them to maintain a line ahead formation and so develop their broadside fire to the utmost. Deane was killed, but Blake joined in with reinforcements on the second day and the Dutch fleet was routed, losing over 20 ships. Blake and Monk at once blockaded the Dutch coast, without returning to harbour. This imposed a great strain on the English resources, but it was amply justified by the disorganization of Dutch trade which quickly followed, Tromp with the main fleet being confined to the Weimers while a small force under de Witt lay in the Texel. Early in July the English fleet had to withdraw to land the sick (among them Blake) and to re-provision, but it was back in position in three weeks, during which time Tromp was unable to make any move owing to lack of men, ammunition and stores. At last on July 25 Tromp put to sea and, heading north, succeeded in drawing Monk south from the Texel in a running fight, after which he slipped north during the night of July 29 and effected a junction with de Witt. The action which followed on July 31 (OS) was the fiercest of the whole war. Tromp, who throughout the operations had shown marked superiority in seamanship, obtained the wind and attacked with over 100 sail. The fight lasted nearly 12 hours, by which time the Dutch were completely beaten and had lost 30 ships, while many deserted earlier in the action, and Tromp himself was killed. No other operations of any importance followed, and by the Treaty of Westminster, concluded in April 1654, the Dutch conceded all trade questions under dispute, acquiesced in the Navigation Act, and paid a heavy indemnity. In the Far East their commercial expansion was checked, though in the Mediterranean they remained supreme.

Second Dutch War (1664-67)—Charles II's government pursued a vigorous commercial policy, and was soon embroiled with the Dutch over the West African slave trade, and the interpretation of the Navigation Act. In Oct. 1663, therefore, Captain Robert Holmes was sent to raid the Dutch West African trading posts, and in 1664 he crossed the Atlantic and captured the Dutch colony of New Amsterdam (New York). The Dutch at once sent out Admiral de Ruyter, who recaptured the African ports and attacked Barbados. He was on his way home when, in May 1665, official operations of war began, and a Dutch fleet of over 100 sail under the lord of Opdam captured some English ships which were bringing naval stores from Hamburg. The English fleet, of equal strength, was at once hurried to sea under James, duke of York, then lord high admiral. He was assisted by Prince Rupert, Lord Sandwich and Sir William Penn, and encountered the Dutch off Lowestoft on June 3 (OS). The action lasted all day and resulted in the decisive defeat of the Dutch, after a total loss of over 30 ships, Opdam being blown up in his flagship and Cornelius Van Tromp, the son of Admiral Martin Tromp, covering the Dutch retreat with great skill. Great dissatisfaction was shown at the duke of York's failure to pursue the enemy, and he was quickly replaced by Sandwich who, after a short time, was himself replaced by Monk (now duke of Albemarle), together with Prince Rupert.

The Plague, meanwhile, had so disorganized English administration that no further operations could be undertaken till May 1666, when Monk and Rupert were ready in the Downs with 80 sail. Here they received orders from Charles II to detach one of their three squadrons, to meet a French squadron said to be

approaching up channel from the Mediterranean, whence all English war-ships had recently been withdrawn. The French had declared war, but their squadron never came north of Lisbon, and the east wind, which took Rupert to Portsmouth with 25 sail, brought de Ruyter out with 85 ships against Albemarle's weakened force. Nevertheless, when the wind changed to south west on June 1 (OS), he attacked the Dutch brilliantly, trying to concentrate the whole of his force against their van. In this he was partially successful, the Dutch vice-admiral Everzen was killed during the action, which lasted all day. On June 2 the Dutch were reinforced, and continued the fight. Their van was disorganized owing to Everzen's death, and Albemarle concentrated all his force against the rear under Tromp, who was at last relieved by de Ruyter, when Albemarle retired. On June 3 Albemarle continued his retirement, protecting his injured ships with great skill, though Sir George Ayscue surrendered the "Royal Prince" after running on the Galloper shoal. In the evening Rupert and his squadron returned, and on June 4 Albemarle again offered battle and a great *meelee* ensued, the English finally retiring into the Thames after a total loss of nearly 20 ships. De Ruyter now blockaded the Thames, based on the Essex shore, but Albemarle and Rupert quickly refitted and, working their way through the shoals, eventually forced him into action on St. James's day, July 25, off the North Foreland, where he was completely defeated with a loss of 20 ships. Albemarle now crossed to the Dutch coast and on Aug. 8-9 a special force under Sir Robert Holmes burnt 160 merchantmen anchored in the Vlie Channel and a million pounds' worth of goods in storehouses on shore.

Peace negotiations now began, but the English, exhausted by the war, the Plague and the Great Fire, laid up their line of battle ships for the winter, and the Dutch, pretending to do the same, resolved on a desperate raid in order to obtain better terms. Early in June 1667 de Ruyter suddenly appeared in the Thames and, forcing an entrance into the Medway Channel, despite the forts and boom protecting it, did immense damage to the shipping lying there, burning three first raters, capturing another, and causing a panic in London. By the Peace of Breda (July 1667) the Dutch ceded New York, and the Navigation Act was amended in their favour.

Third Dutch War (1672-74)—Unlike the two previous wars, which were entirely commercial, this war was part of a great European political struggle. Louis XIV. who was intent on seizing the Spanish Netherlands, had recently been checked by the Triple Alliance of England, Sweden and the United Provinces, but in 1670 by the "Secret Treaty of Dover" he had persuaded Charles II to abandon his former allies and co-operate with the French. The English and French fleets were to be combined under an English admiral, Charles was to establish Roman Catholicism in England, and was to receive large money subsidies. The Dutch, anxious to avoid a simultaneous war by land and sea, made every possible concession demanded of them and finally no better way of provoking them could be found than to order Sir Robert Holmes to attack their Smyrna convoy in the Channel (March 13, 1672).

De Ruyter with about 80 sail was at once ordered to sea, but administrative difficulties made him too late to prevent the junction of the French fleet of 35 sail under d'Estrees with the English fleet of 55 sail under James, duke of York, assisted by Lord Sandwich, Sir John Harman and Sir Edward Spragge. The allies, however, were also suffering from hasty preparation, and went to Solebay on the Suffolk coast to complete their complements and stores. Early in the morning of May 28, 1672, they were surprised by de Ruyter while still at anchor. Sandwich with the Blue squadron at once stood to the north and engaged the Dutch, and though his flagship was burnt and he himself drowned his squadron routed the one opposed to it under Van Ghent, who was also killed. Meanwhile, the French turned south and held off from the battle, and de Ruyter, merely detaching a small force to watch them, concentrated his attack on the English centre. Here the duke of York was very hard pressed and had to shift his flag twice, and only the arrival of the ships of the Blue

quadron prevented complete disaster, after which de Ruyter drew off.

The Test Act now forced the retirement of the duke of York and many other Catholic officers, and no further operations were attempted till 1672, when the allied fleet was commanded by Prince Rupert, and it was planned to land troops on the Dutch coast. The Dutch, who were also attacked by Louis XIV on land, passed through an interval of relative quiet which brought William, prince of Orange, to the chief naval and military command. He at once ordered de Ruyter to sea, but there was hardly enough ammunition for both army and fleet. De Ruyter occupied a well-chosen anchorage in the Schooneveldt channel from where he could command his own coast. On May 28, 1673, the allied fleet attacked him with six ships and frigates, but were severely handled and driven back on their main fleet, de Ruyter counter-attacking with great skill and the fight lasting till night, when the Dutch again retired to their own coast.

On June 4 de Ruyter himself made a sortie and caught the allies somewhat dispersed, and after a running fight again retired to his shoals the allies returning to the Thames to refit. De Ruyter now attempted to blockade them, but was driven back by plague in his ships, and at the end of July the allies returned in force to blockade the Dutch ports, and threatened an invasion from the east coast. William of Orange ordered de Ruyter to break the blockade and relieve the Dutch trade at all costs. De Ruyter found the allies off the Texel and, through the deliberate slowness of the French, easily out-maneuvred them and obtained the weather gauge. On Aug. 11, 1673, he again had the wind, and attacked them running south. The French, who were leading, attempted to surround his van and, having failed, withdrew from the action. Sprague in the rear fought a magnificent but detached action with Cornelius Tromp, regardless of the general tactics of the battle. The French having disappeared, de Ruyter was again able to concentrate superior numbers against the English centre, which was very hard pressed. The centre and rears now became confused in a general *mêlée* and Sprague was drowned while crossing in a boat to his third ship. Great efforts were made to capture his first ship, the "Royal Prince," but she was splendidly defended, and towards evening the French returned and the Dutch withdrew. The unpopularity of the war in England compelled the English government to make peace with the Dutch in the following year.

Meanwhile, a revolt in Sicily led the insurgents to seek help from the French against their Spanish rulers, and a French army occupied Messina. The Spaniards appealed to the Dutch for help, and de Ruyter took out a squadron and fought an indecisive action on Jun 8, 1676, with Duquesne who was bringing French reinforcements to Sicily. Later, a combined Hispino-Dutch attack on Messina failed, and de Ruyter was mortally wounded off Augusta on April 22. Charles II now made a treaty of alliance with the Dutch, despatched troops to help them in Flanders, and sent Sir John Narbrough to the Mediterranean, on which the French evacuated Sicily and, in 1678, made the peace of Nijmegen.

OPERATIONS ON LAND

The contemporary military history of Europe included, first, the war between France and Spain, 1654-59, usually called the Spanish Fronde (see *FRONDE*, *THE*), of which the most notable incident was the great battle of the Dunes (q.v.). About the same time a war was fought in northern Europe (1655-60), celebrated chiefly for the three days' battle of Warsaw (July 28-30, 1656), and the successful invasion of Denmark by the Swedes, carried out from island to island over the frozen sea (Feb. 1658), and culminating in a long siege of Copenhagen (1658-59). Between the second and third wars of England and the United Provinces came the short War of Devolution (1667-68)—a war of sieges in the

Low Countries in which the French were commanded chiefly by Turenne. In 1668 the French under Condé made a rapid conquest of Franche Comté. This was, however, given up at the peace. The war of 1672-78, the first of the three great wars of Louis XIV, was fought on a grander scale.

Invasion of Holland, 1672.—The diplomacy of Louis had, before the outbreak of war, deprived Holland of her allies—England (Treaty of Dover, 1670), Sweden (Treaty of Stockholm, 1672) and the emperor, and when he declared war on the United Provinces in March 1672, it seemed that the Dutch could offer little resistance. The French army under Louis in person started from Charleroi and marched down the Meuse unopposed. The powerful Dutch fortress of Maastricht was masked, and the French then moved towards Dusseldorf. In the electorate of Cologne they were in friendly country, and the main army soon moved down the Rhine from Dusseldorf, the corps of Turenne on the left bank, that of Condé on the right. At the same time a corps under Marshal Luxembourg, composed of Louis' German allies (Cologne and Munster) moved from Westphalia towards Over-Yssel and Groningen. The Rhine fortresses offered but little resistance to the advance of Turenne and Condé. William of Orange with a weak field army tried to defend the Yssel-Rhine line, but the French rapidly forced the passage of the Rhine at Tolhuis (June 12) and passed into the Betuwe (between the Lek and the Waal). Condé now advised a cavalry raid on Amsterdam, but Louis, acting on the suggestion of the war minister, Louvois, preferred to reduce Nijmegen, Gorinchem and other places, before entering Utrecht province. Condé's plan was, however, partially carried out by Count Rochefort, who with 1,800 troopers captured successively Amersfoort and Naarden. His further progress was checked at Muiden, which the Dutch garrisoned in the nick of time, and he returned to the main army, taking Utrecht *en route*. Louis now moved on Amsterdam, brushing aside the feeble opposition which was offered, and it seemed that the French must achieve their object in one short campaign. But the Dutch people were roused. The month before, the citizens of Utrecht had refused to raze their suburban villas, and defence of the fortifications had consequently been impossible. Now, the dikes were cut and the sluices opened, and Amsterdam was covered by a wide inundation, against which the invader was powerless. At the same time the men of Zeeland repulsed a French raid from Aath on Aardenburg, and this infraction of the neutrality of the Spanish Netherlands served but to raise up another enemy for Louis. Luxembourg too, at first successful, was repulsed before Groningen. A revolution placed William of Orange at the head of the Government. The alliance of Brandenburg and the Rhine electorate had already been secured, and Spain, justly fearing for the safety of her Flemish possessions, soon joined them. The emperor followed, and Louis was now opposed, not by one State, but by a formidable coalition.

War Against the Coalition.—In the autumn the war spread to the Rhine. No attempt could be made on Amsterdam until the ice should cover the floods. Turenne was therefore despatched to Westphalia and Condé to Alsace, while a corps of observation was formed on the Meuse to watch the Spanish Netherlands. But the coalition had not yet developed its full strength, and Turenne's skill checked the advance of the Imperialists under Montecuccoli and of the Brandenburgers under the Great Elector. A war of manoeuvre on the middle Rhine ended in favour of the French, and the allies then turned against the territories of Cologne and Munster, while William, disappointed in his hopes of joining forces with his friends, made a bold, but in the end unsuccessful, raid on Charleroi (Sept.-Dec. 1672). The allies in Germany were now not merely checked, but driven from point to point by Turenne, who displayed a degree of energy rare in the military history of the period. After a severe winter campaign, the elector, defeated in combat and manoeuvre, was forced back to the Weser, and being but weakly supported by the Imperialists, found himself compelled to make a separate peace (June 6, 1673). Turenne then turned his attention to the Imperialists who were assembling in Bohemia, and made ready to meet them at Wetzlar. Meanwhile the other French armies were

fully employed. During the winter, Luxemburg made a bold attempt to capture Leyden and The Hague by marching a corps from Utrecht across the frozen inundations. But a sudden thaw imperilled his force and he had to make a painful retreat along the dikes to Utrecht. And Conde, who then returned to the command of the army in Holland, failed to make headway against the defence of Amsterdam. Louis' own army, originally collected for the relief of Charleroi in December (advanced on Maastricht, and after a brief siege, in which Vauban directed the besiegers, captured this most important fortress (June 29, 1673). Louis, after the capture of Maastricht, led his army southwards into Lorraine and overran the electorate of Trier. But nothing of importance was gained, and Turenne's summer campaign was wholly unsuccessful.

Capture of Bonn.—From Wetzlar he moved to Aschaffenburg. Soon the Imperialists advanced in earnest, greatly superior in numbers. Marching via Eger and Nuremberg (Sept. 3) on the Main, Montecucculi drew Turenne to the valley of the Tauber, then, having persuaded the bishop of Wurzburg to surrender the bridge of that place, he passed to the right bank of the Main before Turenne could intervene. The Imperialists soon arrived at Frankfurt, and the French position was turned. Montecucculi thus achieved one of the greatest objects of the 17th century strategist, the wearing down of the enemy in repeated and useless marches. The French retreat to the Rhine was painful and costly, and Montecucculi then passed that river at Mainz and made for Trier. Turenne followed, unable to do more than conform to his opponent's movements, and took post to defend Trier and Alsace. Thereupon Montecucculi turned northward to meet William of Orange, who evaded Conde's weak army and marched rapidly via Venlo (Oct. 22) on Coblenz. The elector of Trier, who had not forgotten the depredations of Louis' army in the spring, followed the example of the bishop of Wurzburg and gave a free passage at Coblenz. William and Montecucculi joined forces in the electorate and promptly besieged Bonn. This fortress fell on Nov. 12, and the troops of the coalition gained possession of an unbroken line from Amsterdam to the Breisgau, while Louis' German allies (Cologne and Munster), now isolated, had to make peace at once. Louis' allies were leaving him one by one. The German princes and the empire itself rallied to the emperor, Denmark joined the coalition (Jan. 1674), the Great Elector re-entered the war, and soon afterwards England made peace.

Operations of 1674.—In 1674 therefore Louis reluctantly evacuated those of the United Provinces occupied by his army. He had derived a considerable revenue from the enemy's country, and he had moreover quartered his troops without expense. The resources of the French Government were almost intact for the coming campaign, the corps of observation in Roussillon, under Marshal Schomberg, made a successful campaign against the Spaniards, and the war was carried even into Sicily. Conde, in the Spanish Low Countries, opposed with inferior forces the united army of Spaniards, Dutch and Austrians under William, and held the Meuse from Grave to Charleroi on the Sambre. The war in this quarter was memorable for Conde's last, and William's first, battle, the desperate and indecisive engagement of Seneffe (Aug. 11), in which the two armies lost one seventh of their strength in killed alone. The king's part in the campaign was, as usual, a war of sieges, an army under his personal command overran Franche-Comte in six weeks, and Louis, aided by the genius of Vauban, reduced Besançon in nine days. Turenne's Rhine campaign began with an invasion of Germany, undertaken to prevent interference with Louis in Franche-Comte. Bournonville, the imperial commander who now replaced Montecucculi, lay in the Cologne and Trier electorates. An army of South Germans, in the Breisgau, under the duke of Lorraine and Count Caprara, moved northward to the Neckar valley to unite with Bournonville. Turenne determined to attack the southern army before the junction could be effected. He crossed the Rhine at Philippsburg early in June, and on the 16th fell upon the inferior forces of Caprara in their entrenched position of Sinshem. The result of the battle was a complete victory for the French, who followed up their success by driving a portion of Bournonville's army (on

which the duke of Lorraine had rallied his forces) from the Neckar (action of Lidenburg near Heidelberg, July 7). Turenne then laid waste the Palatinate, in order that it should no longer support an army, and fell back over the Rhine ignoring the reproaches of the elector palatine, who vainly challenged him to a duel. This devastation has usually been considered as a gravestain on the character of the commander who ordered it, but Turenne's conception of duty did not differ in this respect from that of Cromwell, Marlborough, Wellington and the generals of the American Civil War. It was held to be necessary and expedient, and it was accordingly carried out. Bournonville's army near Frankfurt was still to be dealt with, and the Great Elector and his Brandenburgers were rapidly approaching the Main valley. After a slight attempt to invade Lorraine, which Turenne easily stopped, the Imperialists suddenly recrossed the Rhine and marched rapidly into the neighbourhood of the Strasbourg bridge.

Turenne's Winter Campaign in Alsace.—The magistrates of this city were not less amenable than had been the bishop of Wurzburg in 1673. Bournonville obtained a free passage, and Turenne was too late to oppose him. The French general, however, determined to fight, as he had done at Sinshem, to prevent the junction of the two hostile armies. The Great Elector was still in the Neckar valley when the battle of Enzheim (8m from Strasbourg) was fought on Oct. 4. This time it was indecisive, and Bournonville's superior forces, soon augmented by the arrival of the elector, spread into Alsace. Turenne steadily retired to his camp of Dettweiler, unable for the moment to do more, and the Germans took up winter quarters in all the towns from Belfort to Strasbourg (Oct.-Nov. 1674). But Turenne was preparing for another winter campaign, the most brilliant in the great commander's career.

First he placed the fortresses of middle Alsace in a state of defence, to deceive the enemy. Then he withdrew the whole of the field army quietly into Lorraine. Picking up on his way such reinforcements as were available, he marched southward with all speed behind the Vosges, and in the last stages of the movement he even split up his forces into many small bodies, that the enemy's spies might be misled. After a severe march through hilly country and in the midst of snowstorms, the French reunited near Belfort, and without a moment's delay poured into Alsace from the south. The scattered Imperialists were driven towards Strasbourg, every corps which tried to resist being cut off. Bournonville stood to fight at Mulhausen with such forces as he could collect (Dec. 29, 1674), but Turenne's men carried all before them. The advance continued to Colmar, where the elector, who was now in command of the Germans, stood on the defensive with forces equal to Turenne's own. The battle of Turkheim (q.v.) (Jan. 5, 1675) nevertheless resulted in another and this time a decisive victory for the French, a few days after the battle Turenne could report that there was not a soldier of the enemy left in Alsace. His army now went into winter quarters about Strasbourg, and drew supplies from the German bank of the Rhine and even from the Neckar valley (Jan. 1675).

Operations of 1675.—This opening of the campaign promised well, and Louis as usual took the field as early as possible. In the course of the spring (May-June) the king's army recaptured some of the lost fortresses of the Meuse and took in addition Liège and Limburg. The expeditionary corps in Sicily also gained some successes in this campaign, and Schomberg invaded Catalonia. On the Rhine was fought the last campaign of Turenne and Montecucculi. The elector having withdrawn his forces to Brandenburg (see SWEDEN History), Montecucculi resumed command, and between Philippsburg and Strasbourg the two great commanders manoeuvred for an advantage, each seeking to cover his own country and to live upon that of the enemy. At last Turenne prevailed, and had the Imperialists at a disadvantage on the Sasbach, where, in opening the action, he was killed by a cannon shot (July 27). The sequel showed how dependent was even the best organized army of the time upon the personality of its commander.

All the advantages won were hastily surrendered, and Montecucculi, sharply following up the retreat of the French, drove

them over the Rhine and almost to the Vosges. At the same time the duke of Lorraine defeated Marshal Créquy (Aug. 11) at Conzér Brucke on the Moselle and recaptured Trier (Sept. 6), which, as a set-off against Bonn, Turenne had taken in the autumn of 1673. The situation was more than alarming for the French but Conde was destined to achieve a last success—for once a success of careful strategy and prudent manoeuvre. Luxembourg was left in charge in Flanders, and Conde took command of the remnant of Turenne's old army and of the fugitives of Créquy's Montecuccoli's skill failed completely to shake his position and in the end Conde compelled him to retire over the Rhine. Both retired from their commands at the close of the year, Turenne was dead, and a younger generation of commanders henceforward carried on the war.

Operations of 1676—In 1676 the naval successes of France in the Mediterranean enabled the corps under Marshal Vivonne in Sicily to make considerable progress, and he won in important victories at Messina (March 3). Vivonne was made viceroy of Sicily. Louis himself, with his marshals and Vauban, conducted the campaign in the north. The town of Conde fell on April 26, and the king then manoeuvred against the prince of Orange in the neighbourhood of Valenciennes. An attempt made by the latter in the summer to besiege Maastricht was frustrated by Marshal Schomberg with a detachment of the king's army (August). Rochefort meanwhile covered the Meuse country and Luxembourg Créquy, who had now returned from captivity (he had been taken after the battle of Conzér Brucke) opposed the Imperialists in Lorraine, but he was unable to prevent the fall of Philipsburg, which occurred on Sept. 17. The French now had waste the land between the Meuse and Moselle for the same reason which brought about the devastation of the Palatinate in 1674, and the year closed with a war of manoeuvre on the upper Rhine between the Imperialists under the duke of Lorraine and the French under Luxembourg.

Operations of 1677 and 1678—The chief event of the campaign of 1677 in the Netherlands was the siege of Valenciennes, which fortress was invested by Louis in the first weeks of the campaigning season. Five marshals of France served under the king in this enterprise, but their advice was of less value than that of Vauban, whose plans the king followed implicitly, even so far as to order an assault *de vive force* against the unanimous opinion of the marshals. This succeeded beyond Vauban's own expectation, the picked troops entrusted with the attack of an outwork forced their way into the town itself (March 17). The success was followed by the siege of St. Omer and the defeat of William's relieving army by the duke of Orleans (battle of Mont Cassel, April 11, 1677). The summer campaign was a contest of skill between Luxembourg and William, which resulted in favour of the French.

In Germany the credit of the French successes was due to Créquy, who was no longer the defeated general of Conzér Brucke, but the most successful of Turenne's pupils. He began by driving back the duke of Lorraine to the Rhine. Another attempt by the Lorraine family to reconquer their duchy was thus foiled, and at the same time a second imperial army, which had crossed the Rhine by Philipsburg, was shut up in an island of the Rhine and forced to make terms with the French. A large reinforcement sent by the duke of Lorraine to its assistance was completely defeated by Créquy in the battle of Kochersberg near Strasburg (Oct. 7) and the marshal followed up his successes by the capture of Freiburg on Nov. 14. During the year there was a brisk war in the West Indies, and also in Catalonia, where the French maintained the ground won by Schomberg in the previous campaign.

In 1678 Louis took the field in February. The skilful manoeuvres of the French, whether due to Louis' own generalship or that of his advisers, resulted in the speedy capture of Ghent and Ypres (March), and the retention of the prizes in the usual war of posts which followed. The last battle of the war was fought at St. Dennis (outside Mons) between William and Luxembourg on Aug. 14, three days after the peace of Nijmegen had been concluded. William sustained another defeat, but the battle was one of the most fiercely contested of the whole war. On the

Rhine Créquy began by winning the battle of Rheintelden (July 6), after which he inflicted upon the Imperialists another defeat at Gengenbach (July 23) and took Kehl. In the short campaign of 1679 before France and the empire had concluded peace, he was equally successful.

In Spain the French army under Marshal de Navailles had made moderate progress, and thus the last campaign was wholly in favour of the French. The peace of Nijmegen gave Louis many of the Netherlands frontier fortresses, and little else. He was thenceforward the intervention of England on the side of the coalition and would have made peace earlier but for his reluctance to abandon his ally Sweden. The French army had, however, well established its reputation. Vauban was unique amongst the officers of his time, and Créquy and Luxembourg were not unworthy successors of Turenne and Conde. The two marshals added to their reputation in the "Reunion War" of 1680-84. Créquy died in 1687. Luxembourg's greatest triumph was won seven years later (see GRAND ALLIANCE, WAR OF THE). Vauban retired from active service as a marshal 25 years after the peace of Nijmegen. But the interest of the war does not reside wholly in the personalities of the leaders. There were great commanders before Turenne and Conde. It is as the debut of a new method of military organization and training—the first real test of the standing army as created by Louvois—that the Dutch War of 1672-79 is above all instructive. (C. F. A.)

DUTCH WEST INDIA COMPANY, THE (*De West Indische Compagnie*), a company founded by letters patent from the Netherlands states general dated June 3, 1602. The purpose for which the company was formed was to regulate and protect the contraband trade already carried on by the Dutch in the American and African possessions of Spain and Portugal, and to establish colonies on both continents and their islands. By the terms of the charter the company was to be composed of five boards or branches, established in Amsterdam, Zealand, the Meuse (Rotterdam), the North Department (Friesland and Hoorn), and Groningen. Each was to be represented on the general governing board according to the importance of the capital contributed by it. Thus Amsterdam, which contributed four-ninths of the capital, had eight directors on the board. Zealand, which subscribed two-ninths, had four. Rotterdam was represented by two directors. The northern district and Groningen appointed one director each.

The company was granted the monopoly of the trade with America and Africa and between them, from the Arctic regions to the Straits of Magellan, and from the Tropic of Cancer to the Cape of Good Hope. The policy the company proposed to follow was to use its monopoly on the coast of Africa in order to secure the cheap and regular supply of negro slaves for the possessions it hoped to acquire in America. The trade was thrown open by the voluntary action of the company in 1638. The general board was endowed with ample power to negotiate treaties, and make war and peace with native princes, to appoint its officials, generals and governors, and to legislate in its possessions subject to the laws of the Netherlands. The states general undertook to secure the trading rights of the company, and to support it by a subvention of one million guilders (about £100,000). In case of war the states general undertook to contribute sixteen vessels of 300 tons and upwards for the defence of the company, which however, was to bear the expense of maintaining them. In return for these aids the states general claimed a share in the profits, stipulated that the company must maintain sixteen large vessels (300 tons and upwards) and fourteen "yachts" (small craft of 50 to 100 tons or so), required that all the company's officials should take an oath of allegiance to the Netherlands as well as to the board of directors, and that all despatches should be sent in duplicate to the government and to the board.

The history of the Dutch West India Company is one of less prosperity than that of the Dutch East India Company. In early days the trade was not sufficient to meet the heavy expense of the armaments raised against Spain and Portugal. The company was never able to secure the control of the supply of slaves from Africa. Its settlement of New Netherland was lost to England

In the West Indies it gained a valuable footing among the islands. It occupied St. Eustatius in 1634, Curaçao with Bonaire and Aruba in 1634 and 1635, Saba in 1640 and St. Martin in 1648 but its greatest conquests and its greatest losses were alike met on the continent of South America. After a first unsuccessful occupation in 1623, of Bahia, which was immediately retaken by a combined Spanish and Portuguese armament, the company obtained a firm footing in Pernambuco. The story of the wars which arose out of this invasion belongs to the history of Brazil. The company had been largely guided in its policy of assailing the Portuguese possessions by the advice of the Jews, who were numerous in Brazil, and who found means to communicate with their fellows in religion, the refugees in Amsterdam. The most prosperous period of the company was during the tolerant and liberal administration of Count John Maurice of Nassau Siegen (1636-44).

The monopolist tendency of all Dutch colonization, the religious hostility of the Roman Catholic Portuguese, and the support given by France and England to Portugal after her revolt from Spain combined at last to make the position of the company in Brazil untenable. It resigned all claim on the country by the treaty of 1661. But though deprived of its establishment in Brazil the company found a compensation in Surinam and Esse-queibo (Dutch Guiana), where there was no Spanish or Portuguese population to resist it, and where the resources of the country offered great profits. The advantages of the settlement in Guiana were not, however, reaped by the company founded in 1621. In 1674 it had become so embarrassed that it was dissolved, and reconstituted in 1675. The newly formed company continued to exploit the Dutch possessions in America till 1794, when they were all swept into the general reorganization consequent on the French invasion of Holland. The West India Company founded after the Napoleonic epoch in 1828 was only meant to develop trade, and was not successful.

DUTT, MICHAEL MADHU SUDAN (1824-1873), the greatest native poet of India in the 19th century, was born at Sagandari, in the district of Jessore in Bengal, on Jan. 25, 1824. His father was a pleader in Calcutta, and young Madhu Sudan received his education in the Hindu college of Calcutta. In 1843 he ran away to avoid a marriage into which his father wished to force him, and embraced the Christian religion. Continuing his studies now in the Bishop's college, Madhu Sudan learnt Greek and Latin and some modern European languages, and in 1848 went to Madras. There he wrote English verses, and married the daughter of a European indigo-planter, but was soon separated from her. He then married an English lady, with whom he returned to Calcutta in 1856, and soon discovered that the true way to win literary distinction was by writing in his own language, not by composing verses in English. His three classical dramas—*Ratnavali* (1858, Eng. trans. 1904), *Sarmishtha* (1859, Eng. trans. 1859, 1914) and *Krishna Kumari*—appeared between 1858 and 1861, and were recognized as works of merit. But his great ambition was to introduce blank verse into Bengali. His knowledge of Sanskrit poetry, his appreciation of the Greek and Latin epics, and his admiration of Dante and of Milton impelled him to break through the fetters of the Bengali rhyme and to attempt a spirited and elevated style in blank verse. His first poem in blank verse, the *Tilotama*, was only a partial success, but his great epic which followed in 1861, the *Meghnad Badha*, took the Indian world by surprise, and at once established his reputation as the greatest poet of his age and country. He took his story from the old Sanskrit epic, the *Ramayana*, but the beauty of the poem is all his own, and he imparted to it the pathos and sweetness of Eastern ideas combined with the vigour and loftiness of Western thought. In 1862 Madhu Sudan left for Europe. He lived in England for some years, and was called to the bar, and in 1867 returned to his country to practise as a barrister in Calcutta. He still wrote much, but nothing of enduring merit. He died in a Calcutta hospital on June 29, 1873.

DUTT, TORU (1856-1877), Indian poetess, was born in Calcutta on March 4, 1856, and died there of tuberculosis on Aug. 30, 1877. She was the youngest child of Govin Chunder Dutt, member of a distinguished Christian family in Bengal who were noted for their poetical gifts. Toru visited Europe with her parents in 1869 and spent some time in Nice and at Paris. Toru Dutt became an enthusiastic lover of French and French literature, James Darmesteter, in his *Essai de Littérature Anglaise*, states that "French became her favourite language, and France the country of her election." Early in 1870 the family arrived in London, removing in 1871 to Cambridge. On their return to India in 1873 Toru contributed to the *Bengal Magazine* translations into English from the Romantic school of French poetry, which were afterwards published with other pieces, in a volume entitled *A Shiva's Gleaned in French Fields* which won the praise of Andre Theuriot and Sir Edmund Gosse. Her translations of speeches delivered by Victor Hugo and Thiers in the French Legislative Assembly were also published in the *Bengal Magazine* for June and July 1875. Her most remarkable work was a French novel, *Le Journal de Mlle D'Ayres*, dedicated to Lord Lytton, and published post-humously by Didier (Paris 1879), with a preface by the Orientalist, Mlle Clarisse Badier. This book was highly praised by Madame de Staël and James Darmesteter has included an appreciation of it in his *Essays Ancient Ballads and Legends of Hindustan* (London, 1882) constitute Toru Dutt's best work in English. In this book she made available, for the appreciation of English readers, some of the great stories of Indian classical literature and also some beautiful miscellaneous poems. Of these, *Our Casuarina Tree* is rich in imagery and musical cadences.

See H. Das, *Life and Letters of Toru Dutt* (1921). (H. DA.)

DUTY, a term loosely applied to any action or course of action which is regarded as morally incumbent, apart from personal likes and dislikes or any external compulsion. Such action must be viewed in relation to a principle, which may be abstract in the highest sense (e.g., obedience to the dictates of conscience) or based on local and personal relations. That a father and his children have mutual duties implies that there are moral laws regulating their relationship, that it is the duty of a servant to obey his master, within certain limits is part of a definite contract, whereby he becomes a servant engaging to do certain things for a specified wage. Thus it is held that it is not the duty of a servant to infringe a moral law even though his master should command it. For the nature of duty in the abstract, and the various criteria on which it has been based, see ETHICS.

From the root idea of obligation to serve or give something in return, involved in the conception of duty, have sprung various derivative uses of the word, thus it is used of the services performed by a minister of a church, by a soldier, or by any employee or servant. A special application is to a tax, a payment due to the revenue of a state, levied by force of law. Properly a "duty" differs from a "tax" in being levied on specific commodities, transactions, estates, etc., and not on individuals, thus it is right to talk of import duties, excise-duties, death- or succession duties, etc., but of income-tax as being levied on a person in proportion to his income.

DUUMVIRI or **DUOVIRI**, in ancient Rome, the official style of two joint magistrates. Such pairs of magistrates were appointed in Rome itself and in the colonies and municipia. (1) *Duumviri iuris (sive) dicundo*, municipal magistrates, whose duties were concerned with the administration of justice. (2) *Duumviri quinquennales*, municipal officers, who were elected every fifth year for one year to exercise the function of the censorship. (3) *Duumviri sacrorum*, officers who originally had charge of the Sibylline books (see DECEMVIRI). (4) *Duumviri aedi locandae*, originally officers specially appointed to supervise the erection of a temple. (5) *Duumviri navales*, officers appointed for the equipment of a fleet. Originally chosen by consuls or dictators, they were elected by the people after 311 B.C. (6) *Duumviri perduellionis*, the earliest criminal court for trying offences against the State (see TREASON). (7) *Duumviri viis extra urbem purgandis*, subordinate officers under

the aediles, whose duty it was to look after those streets which were outside the city walls. By 12 B.C. their duties were transferred to the *Curatores vicarum*.

BIBLIOGRAPHY.—See Falciger and Lieberman in Pauly Wissowa, *Realenzyklopädie*, II. H. J. Crendel, *Roman Public Life* (1904), J. E. Sandys, *Companion to Latin Studies* (1913), with a useful bibliography, W. I. Heitland, *The Roman Republic* (1923).

DU VAIR, GUILLAUME (1556–1621), French author and lawyer, was born in Paris. Du Vair was in orders, and, though during the greater part of his life he exercised only legal functions he was, from 1617 till his death, bishop of Lisieux. His reputation, however, is that of a lawyer, a statesman and a man of letters. He became in 1583 councillor of the parliament of Paris and is deputy for Paris to the Estates of the League; he pronounced his most famous politico-legal discourse, an argument nominally for the *lex talis* but in reality directed against the alienation of the crown of France to the Spanish infants. In 1595 appeared his treatise *De Ploquino francense*. He was sent to England in 1596 with the marshal de Bouillon to negotiate a league against Spain; he became (1599) first president of the parliament of Provence (Aix), and in 1616 keeper of the seals. He died at Tonnens (Lot-et-Garonne) on Aug. 3, 1621. The most celebrated of his treatises are *La Philosophie morale des Stoïques*, translated into English (1664) by Charles Cotton; *De la constance et consolation en calamités publiques*, composed during the siege of Paris in 1589, and translated into English as *1. Buckler against Adversity* (1622), and *La Santé Philosophique*, in which religion and philosophy are intimately connected. Pierre Charron drew freely on these and other works of Du Vair who had a great indirect influence on the development of style in French; for Malherbe was an admirer of his writings. The reformer of French poetry learned much from the treatise *De Ploquino francense*, to which the counsels of his friend were no doubt added.

Du Vair's works were published at Paris in 1641. See Nicéron, *Mémoires*, vol. xliii, and monographs by C. A. Sapey (1847 and 1858).

DUVAL, ALEXANDRE VINCENT PINEUX (1767–1847), French dramatist, was born at Rennes on April 6, 1767. He was in turn sailor, architect, actor, theatrical manager and dramatist. Of his 60 or more plays *Les Projets de ménage* (1790), *Les Fugitifs vengés* (1794) and *Les Héritiers* (1796) have been revived on the modern French stage. In 1812 he was elected to the Académie. He died on Sept. 1, 1847.

DUVAL, CLAUDE (1643–1670), a famous highwayman was born at Domfront, Normandy, in 1643. Having entered domestic service in Paris, he came to England at the time of the Restoration in attendance on the duke of Richmond, and soon became a highwayman notorious for the daring of his robberies and his gallantry to ladies. In the end he was captured in London and hanged at Tyburn on Jan. 21, 1670. His body was buried in the centre aisle of Covent Garden church, under a stone with the following epitaph—

"Here lies Du Vall. Reader if male thou art,
Look to thy purse if female to thy heart."

A full account of his adventures ascribed to William Pope, was reprinted in the *Harleian Miscellany*, and Samuel Butler published a satirical ode *To the Happy Memory of the Most Renowned Du Vall*.

DUVENECK, FRANK (1848–1910), American figure and portrait painter, was born at Covington, Ky., Oct. 9, 1848. He was a pupil of Diaz in the Royal Academy of Munich, and a prominent member of the group of Americans who in the '70s overturned the traditions of the Hudson river school and started a new art movement. His work shown in Boston and elsewhere about 1875 attracted great attention and many pupils flocked to him in Germany and Italy, where he made long visits. After returning from Italy to America he gave some attention to sculpture, and modelled a fine monument to his wife, now in the English cemetery in Florence. In 1915 he presented to the Cincinnati (O.) Museum a large collection of his own works. He died in Cincinnati, Jan. 3, 1910.

DU VERGIER DE HAURANNE, JEAN (1581–1643), abbot of St. Cyran, father of the Jansenist revival in France, was

born of wealthy parents at Bayonne and studied theology at Louvain. After taking holy orders he settled in Paris, where he became known as a mine of miscellaneous erudition. His friend ship with Cornelius Jansen, a young champion of Augustinianism, led him to oppose the Louvain Jesuits who stood for Scholasticism. The two divines retired to Du Vergier's home at Bayonne, where he became a canon of the cathedral, and Jansen a tutor in the bishop's seminary. Here they remained some years, intently studying the fathers. Eventually, Jansen went back to Louvain, while Du Vergier became confidential secretary to the bishop of Poitiers, and was presently made succent abbot of St. Cyran. Thenceforward he was generally called M. de St. Cyran. At Poitiers he met Richelieu—as yet simply the zealous young bishop of the neighbouring diocese of Luçon. Western Touraine being the headquarters of French Protestantism, the two prelates turned St. Cyran's learning against the Huguenots. He began to dream of reforming Catholicism on Augustinian lines, and thus defeating the Protestants by their own weapons. They appealed to primitive antiquity, he answered that his Church understood antiquity better than theirs. They appealed to the spirit of St. Paul, he answered that Augustine had saved that spirit from eternalizing away by coupling it with a high sacramental theory of the Church. They slung practical abuses in the teeth of Rome, he entered on a bold campaign to bring those abuses to an end. Before long his reforming zeal necessitated his removal to Paris where his attempt to gain the support of influential people led to his friendship with the Arnauld family. Jansen was now attacking Jesuit dialectics, which he thought had corrupted theology, by writing a book on Augustine, the great master of theological method.

St. Cyran attacked their hand to mouth utilitarianism, which had played havoc with traditional church institutions and their defiance of episcopal authority by his *Petrus Anselmus* (1633).

This work so annoyed Richelieu, now the powerful and extremely Erastian prime minister, that St. Cyran was imprisoned until Richelieu's death in 1642. St. Cyran himself died of a stroke of apoplexy in Oct. 1643.

St. Cyran's character has been always something of a puzzle. Many excellent contemporary judges were profoundly impressed, others, as one of them said, went away bewildered by this strange tale, who leapt from one point to another in incoherent phrases. Grace of expression he had none, perhaps no man of equal spiritual insight ever found it so hard to make his meaning clear. On the other hand, Jansenism, considered as a practical religious revival, is altogether his work.

He dragged the Augustinian mysticism out of the Louvain classrooms, and made it a spiritual force in France. Without him there would have been no Pascal—no Provincial Letters, and no *Pensées*.

See C. Lancelot, *Mémoires de M. de S. Cyran* (Cologne, 1718), Sainte-Beuve, *Port-Royal*, 5 ed. (1888). J. Laporte, *La doctrine de Port Royal*, vol. 1 (1923) contains a list of the printed and ms. works of St. Cyran.

DUVEYRIER, HENRI (1840–1892), French explorer of the Sahara, was born in Paris, and at the age of 19, having already learnt Arabic, began a journey in the northern parts of the Sahara which lasted nearly three years. In 1864 he published *Exploration du Sahara les Touareg du nord*. After 1870 he made several other journeys in the Sahara. He also examined the Algerian and Tunisian *shats* and explored the interior of western Tripoli.

Duveyrer devoted special attention to the customs and speech of the Touareg, and to the organization of the Senussi. In 1881 he published *La Tunisie*, and in 1884 *La Confrérie musulmane de Sidi Mohammed Ben Ali Es Soudous et son domaine géographique*.

See C. Maunoir and H. Schivmer, *Sahara, Algérie et Tunisie* with a Biography of Duveyrier by C. Maunoir (1905).

DUX, BOHEMIA see DUCHOV

DUX (Lat., leader), in music, an old name for the opening statement of the subject in a fugue, so called because, coming first it is the "leader", the second statement, or answer being

called, in the same fanciful spirit, the *comes* or companion (See FUGUE and CONTRAPUNTAL FORMS)

DUXBURY, a town of Plymouth county, Massachusetts, on Plymouth bay, 36 mi SSE of Boston. The population in 1950 was 3,149, and in 1940 it was 2,359 by the federal census. Duxbury was settled in 1631 by Miles Standish, William Brewster, John Alden and a few others, and it was named after the Lancashire seat of the Standish family. A church was organized in 1632 and the town was incorporated in 1637. The house built in 1666 by Alexander Standish, son of Miles, is still standing. The cod, mackerel and clam fisheries were formerly important, and in the 18th century and the first half of the 19th there were large shipyards here.

DVINA, the name of two rivers of European Russia.

1. The Northern Dvina, or *Dvina Syevernaya*, belongs to the basin of the White sea, and is formed by the junction of the Sukhona and the Yug, which meet in the neighbourhood of Veliky-Ustyug, at a height of 300 ft above the sea, in 61°20' N and 46°20' E. The conjoint stream then flows north-west to the Gulf of Archangel, which it reaches 50 m below the city of Archangel. From its mouth to the confluence of the co tributary streams the distance is about 470 m, and to the source of the Sukhona 780 m. The drainage area is estimated at 141,000 sq m. Except at the rapids the current of the Dvina is comparatively slow, as the average fall per mile is only 9 in. Till its union with the Vychegda, a river which exceeds it in volume, it flows for the most part in a single, well-defined and permanent channel, but below that point it often splits into several branches, and not infrequently alters its course. Near Archangel it divides into three distinct arms, which form a regular delta, but of these that of Beregov alone is navigable for sea-going vessels, and even it is impeded by a bar at the mouth, with not more than 14½ or 15½ ft of water at full tide. Just above the point where the delta begins the river is joined by a large tributary, the Pinega, from the right. Above the confluence of the Vychegda the breadth is about 1,750 ft, below that point it widens out to 3,500 ft, and near Archangel it attains more than three times that measure. The channel is free from ice for about 174 days in the year. By means of the Duke Alexander of Württemberg Canal, the river is connected with the Neva and the Volga.

2. The Southern Dvina, or *Dvina Zapadnaya* (western Dvina) belongs to the Baltic basin, and takes its rise in a small lake about 800 ft above the level of the sea, not far from the sources of the Volga and the Dnieper. It flows south west through the province of Pskov, and through the White Russian SSR. But some distance west of Vitebsk it turns north west, forming part of the boundary between White Russia and Poland, and then flows through Latvia where it enters the southern end of the Gulf of Riga. Its length is 640 m and it drains an area of 34,960 sq m. From Daugavpils (Dvinsk) to Riga, a distance of 135 m, there is altogether a fall of 295 ft, of which 105 ft are in the 40 m from Jakobstadt to Friedrichstadt. In the lower part of its course the river attains an ordinary depth of 30 ft and an average breadth of 1,400 ft, but during the spring flood it sometimes rises 14 ft above its usual level, and its waters spread out to a mile in width. Near the mouth the river is usually free from ice for 245 days in the year, and in White Russia 229. It is navigable from the confluence of the Mezha (≠, from Vitebsk) downwards, but the number of rapids and shallows greatly diminishes its value. Navigation can also be carried on by the following tributaries: the

DVOŘÁK, ANTON (dvor'zhahk) (1841-1904). Bohemian musical composer born at Nelahozeves (otherwise Muhlhausen) in Bohemia on Sept. 8, 1841, was the son of František Dvořák, a small publican and village butcher. At the door of his father's inn Dvořák first appeared as a practical musician, taking his place among the fiddlers who scraped out their "lurants" and other wild dances for the benefit of the holiday making local beaux and belles. At the village school he learnt from Josef Spitz both to sing and to play the violin, with so much effect that soon he was able to assist in the parish church services. At 12 years old he was sent by his father to Zlonic, near Schlan, to an uncle, with whom he lived while passing through the higher-grade classes at school. Here, too, he was fortunate enough to find a valuable friend in A. Liehmann, organist and chief musician of the little town, a competent musician, who instructed the boy in elementary theory, organ and pianoforte playing. The theory studies, however, could not long be continued, since Liehmann soon acknowledged in his own dialect that the boy was extraordinarily full of promise ("Aus Tonda, dem Sappermentsbuben 'mal 'was werden konnte!") at the same time realizing that he could not do much to assist. But Dvořák soon left Zlonic for Bohmisch Kamnitz, where he learnt German and advanced his musical studies under Hancke. A year later he was summoned to return to Zlonic to assist his father, who had set up in business there. But his craving for a musical career was not to be checked, and after considerable trouble, his father's consent was obtained to his settling in Prague to devote himself entirely to the study of music.

In Oct. 1857 Dvořák entered the organ-school of the *Gesellschaft der Kirchenmusik*, where he worked for three years. The small financial aid his father was at first able to lend soon ceased, and after being in Prague but a very few months Dvořák found himself practically thrown on his own resources. By playing the viola in a private orchestra and in various ensembles of the town he succeeded in obtaining a precarious livelihood. On the opening in 1862 of the Bohemian Interimstheater, Dvořák, with part of this band, formed the nucleus of the theatrical orchestra, and remained connected with it for 11 years, when he became organist of the church of St. Adalbert. At this time his small stipend was augmented slightly by the fees of a few pupils, though the privations suffered by him and his wife (for he had recently married) must have been great. But in spite of financial worry and of the amount of time he had to devote to his professional duties and private pupils, Dvořák found leisure not only for his own studies of the classics, but also to compose. His work, like his daily life, was beset with difficulties, for he had not the means to provide himself with sufficient music-paper, much less to hire a pianoforte, and it is possible that several of his important early works would never have been written had it not been for the generosity of Karel Bendl, the composer, who helped him in many ways.

Dvořák himself said afterwards that he retained no recollection of much that he then composed. In and about 1864 two symphonies, a host of songs, some chamber-music, and an entire opera, *Alfred*, lay unheard in his desk. The libretto of this opera was made up from materials found in an old almanac. Most of these works were burnt long ago. In 1873 he made his first bid for popularity by his patriotic hymn *Die Erben des weissen Berges* (published many years later as op. 30). Its reception was enthusiastic, and Dvořák's subsequent works were eagerly awaited and warmly received on production. In 1874 his opera *Kong und Kohler* resulted in a fiasco at Prague, owing to its mixture of styles. Nothing daunted, Dvořák recomposed the whole work in three months. In 1875, on the recommendation of Brahms and Hanslick, he obtained a stipend from the Kultus-Ministerium at Vienna, which freed him from care and enabled him to indulge in composition to his heart's content. Following on this success came a commission in 1877 for a series of Slavonic dances, which took the public by storm. Immediately compositions, old and new, began to pour from the publisher. English sympathy was entirely won by the *Stabat Mater* in 1883, and increased by the symphonies which succeeded it, and the cantata *The Spectre's Bride*, based on K. J. Erben's elaboration of

the Bohemian version of the story treated in Burger's *Leonore*. The favourable impression produced by these works was some what lessened by the oratorio *St. Ludmila*, a comparatively feeble work written "to suit English taste" for the Leeds Festival of 1896. Of the three overtures, op. 91, 92, 93, only the *Carnaval* holds its place, but the New World symphony has become one of the most popular works in the modern repertoire, and much of the chamber music, of which there is abundance, may also be regarded as having permanently established itself, and with good reason, too, for it teems with beauties of every kind. So, too, his *Requiem* (op. 89), written for the Leeds Festival of 1890, will certainly be rediscovered, though it will never be regarded as religious music. In 1892, after having frequently visited England, Dvořák became head of the National Conservatory of Music of America in New York. He died in Brno on May 1, 1894.

Dvořák's talent for composition was of the highest order, but success came to him after a long experience of unductive hard ships. The world then informed him in a loud instructive voice that his music had the charm of bucolic naïveté, and he there upon extensively wrote himself down in afflictions of his own simplicity. His first three symphonies, the *Scherzo Capriccioso* and the *Symphonic Variations* will be recognized as great music as soon as criticism ceases to worry about forms, fashions and derivations, and proceeds to attend to permanent values. Brahms, assuredly no friend to diffuse form, was so delighted with Dvořák's violoncello concerto (op. 104, one of his most diffuse yet most inventive works) that he said to Hausmann, "Why did nobody tell me that one could write a 'cello concerto like this!'"

See W. H. Hadow, *Studies in Modern Music* (second series, 1908) (X. D. I. T.)

DVUR KRALOVE or **KONIGSTHOF**, a town of northeast Bohemia, on the left bank of the Elbe. It is a very old city founded by King Wenceslas II. of Bohemia in the 13th century and given by him to his wife, thus deriving its name (the court of the queen). During the Hussite and Austro-Prussian Wars, owing to its important strategic site, it suffered severely. The fertile basin around produces cereals, the basis of its brewing and flour-milling industries, and the town also shares in the cotton weaving of the neighbouring highland valleys. Pop. (1910) 16,588. The town became widely known as a result of the supposed discovery by the notorious Václav Hunka in 1817 of a 13th century ms. containing epic and lyric poems in Czech. Critics headed by Bauer and Masaryk, proved conclusively that the ms. is a forgery.

DWARF, the term generally used to describe an extraordinary under-sized individual of a race of normal stature (*see* *Pygmy*). In Scandinavian mythology the word connoted smallness and deformity, and was used of the dwarfs and gnomes who were supposed to live on the mountains or in the bowels of the earth and to be kings of metals and mines.

Deficiency in stature is sometimes associated with infantilism, in other cases with injury or deficiency of the pituitary gland, or general endocrine deficiencies, with failure of cerebral development. There are two classes, those who are normal in proportions and the disproportionate.

From the earliest historic times there was much competition on the part of kings and nobles to obtain dwarfs as attendants. Members of the Akkadian race of equatorial Africa heard of the courts of the Pharaohs of the early dynasties. Phileas of Cos, poet and grammarian (c. 130 B.C.) tutor of Plotinus, Philadelphus was alleged to be so tiny that he had to wear leaden shoes. He should be blown away. The Romans practised artificial dwarfing, and the Latin *nanus* or *pygma* were terms alternatively used to describe the natural and unnatural dwarf. Julia, the niece of Augustus, had a dwarf named Corpos 2 ft 4 in high, and a freed maid Andromeda, who measured the same.

In later days there have been many dwarf favourites at European courts. British tradition of dwarfs begins in the old ballad "In Arthur's court Tom Thumb did live." The first authentic English dwarf appears to be John Jarvis (2 ft high), who was page to Queen Mary I. Her brother, Edward VI, had his

dwarf Xit. Jeffery Hudson (1619-82), the son of normal parents, at nine years measured scarcely 18 in., though gracefully proportioned. At a dinner given by the duke to Charles I and his queen he was brought in to table in a pie out of which he stepped, and was at once adopted by Henrietta Maria. He followed the fortunes of the court in the Civil War, and was a captain of horse, earning the nickname of "strenuous Jeffery" for his activity. He fought two duels—one with a turkey cock, and a second with Crofts, who came to the meeting with a squirt, but who in the more serious encounter which ensued was shot dead by Hudson, who fired from horseback, the saddle putting him on a level with his antagonist. Twice was Jeffery made prisoner—by the Dunkirkers as he was returning from France and by Turkish pirates. His sufferings during his latter captivity made him grow, and he steadily increased until he was 3 ft 9 in. At the Restoration he returned to England, where he lived on a pension granted him by the duke of Buckingham. He was later accused of participation in the "Popish Plot," and was imprisoned in the Gate House. He was released and shortly after died in the 63rd year of his age.

Henrietta Maria had two other dwarfs, Richard Gibson and his wife Anne. They were married by the queen's wish, and the two together measured only 2 in. over 7 ft. They had nine children, five of whom, who lived were of ordinary stature. Edmund Waller celebrated the nuptials, Evelyn called the husband as the "compendium of a man," and Lely painted them hand in hand. Gibson was miniature painter to Charles I, and drawing master to the daughters of James II, Queens Mary and Anne, when they were children. He began his career as a page, first in a "gentle," next in the royal family, died in 1690, in his 75th year, and is buried in St. Paul's Covent Garden. The last court dwarf in England was Coppermin, a lively little imp in the service of the princess (August 1) of Wales, the mother of George III. The last dwarf retainer in a gentleman's family was kept by Beckford, the author of *Vathek* and builder of Fonthill. He was rather too big to be flung from one guest to another, as used to be the custom at dinner in earlier days when a dwarf was a "necessity" for every noble family.

Of European court dwarfs the most famous were those of Philip IV of Spain, the hunchbacks whose features have been immortalized by Diego de Silva y Velazquez. Stanislaus, king of Poland owned Nicholas Terry (Bebé), who measured 2 ft 9 in. He died in his 23rd year (1764). Richebourg, who died in Paris in 1855, at the age of 90, was only 23 in. high. He began life as a servant in the Orleans family. In later years he was then pensioner. In the Revolution he passed in and out of Paris as an infant in a nurse's arms, but with dispatches, dangerous to carry, in his baby wrappings.

The Pole Borulwaski (1730-1837) at 6 measured 17 in., and in his 30th year reached 39 in. He had a sister shorter than himself by the head and shoulders. Borulwaski was a handsome man, a wit and something of a scholar. He travelled over all Europe, and—born in the reign of George II—died in retirement near Durham, in the reign of Victoria. He is buried at Durham by the side of the 1st Earl of Stephen Kemble.

In 1837 Charles Strickton better known as "Gen Tom Thumb" was born. When 5 he was 31 in. high. In 1844 he appeared in England where he had an extraordinary success. After extensive travel in both hemispheres, Strickton again visited England in 1857 but the man, despite many personal and intellectual qualities, was less attractive than the boy. In 1863 the "General" married the very minute U.S. woman Lavinia Warren (born in 1842). He died on July 15, 1883.

Other modern dwarfs include Signor Hervio Nano, who played at the Olympic theatre, London, in 1843, three Highlanders named MacInlay, children of a Scots shepherd, the shortest of whom was 45 in., a Spaniard, Don Francisco Hidalgo (29 in.), a Dutchman, Jan Hanuema (28 in.), and Mary Jane Youngman (Australia), who at 15 was 35 in. high. She was called the "dwarf giantess" because she was 3 ft 6 in. round the shoulders, 4 ft 3 in. round the waist and 2 ft round the leg. The so-called Aztec dwarfs were exhibited in London in 1853. In 1867 the pair were mar-

ried Che mah, a Chinese, 42 years old and 25 in high, appeared in London in 1880. George Prout (1774-1851), who was less than 3 ft high, was well known in London in the early Victorian period, as a messenger at the houses of parliament.

DWARF TREE see BON SAI

DWARKA, or JIGAT, town, India in Baroda state, near the extremity of the peninsula of Kathiawar, Bombay. Pop. (1941) 10,876.

As the birthplace and residence of Krishna, it is one of the most sacred spots in that part of India, and attracts many thousands of pilgrims.

The port of Ruphran, 1 mi N., is a point of call on the Bombay-Karachi route. Steamers lie offshore.

DWELLING see HOUSE

DWELLINGS, PRIMITIVE Climate imposes the need of shelter, and man can build only with what nature gives him. Even in the civilized 20th century the building materials are mainly local, and in primitive dwellings a closer dependence is shown in the Eskimo *iglu*, the Blackfoot *tipi*, the Australian *womby* or the Andaman hut, of snow, skins, birch bark and turf or palm leaves. Where nature provides caves or rock shelters man builds no houses at all, and these homes are used by the Vedda of Ceylon, the Bushmen of South Africa, the cave dwellers of Kenya or Tanganyika, China, or the Pueblo region of Arizona, as in Europe in Palaeolithic times. (See CAVE.)

In Neolithic settlements pit dwellings or beehive huts formed the family habitations, and wattle and daub houses characteristic of the bronze age continued into the iron age. For pit dwellings, the earth was scooped out and piled in a circular bank, on which a wall of stone was built. The bank, with a drain outside, kept out the wet, and the hollowing of the floor gave more head room under the low roof. This was made of converging stones in the beehive dwellings, or perhaps of skins stretched across or of brushwood or turf where easily procurable. Prehistoric beehive dwellings of loose stones can be seen in outlying parts of the British Isles, and the Scottish shieling or the Norwegian *saeter*, shelters for girls tending cattle in their summer pastures, are of the same type. With skins stretched across the large bones of whale or walrus, similar huts are found among tundra and polar peoples from Lapland to Kamchatka, and from Alaska to Labrador. There is a long entrance tunnel, and the hut may also be entered through the roof, a hole in which acts as door, window and chimney in one. Links may be found to connect these pit or beehive dwellings with the earth lodges of Missouri and the *kiva* of Arizona. Wattle and daub huts, such as those of the Swiss lake dwellings or of the lake village of Glastonbury, are very easily built. Stakes are driven into the ground, and withes or branches wattled in and out for walls, the hollows in the wattling being filled in and plastered over with mud, the thatched roof has overhanging eaves to protect the mud walls. Such houses were used in Scotland down to the end of the 18th century. They are found across Africa from east to west, north and south of the forest region, and are especially characteristic of the central and Lake Chad areas, in which rainless districts walls and roof may be made in one. They occur rarely in America, except in Mexico and Peru, and in southwestern United States.

Pygmy Huts—In a mixed ethnic region, huts are often a truer test of race than language. The most backward peoples show the simplest types. Just as gypsies or travelling tinkers, or boy scouts drive sticks in the ground and hang a piece of sack or a blanket across to act as a windscreen, so the Negro of the Philippines, the Andaman islander or the Semang of the Malay peninsula, who rarely stay two nights in the same place, fix up a plaited mat or a row of boughs and sleep to leeward. If the Semang need more shelter, the boughs may be plaited in a circle and joined overhead, or two screens may be tilted against each other, as in building a house of cards. In their camps the Andamanese raise their mat screens to form a roof propped up on four posts, 2 ft to 4 ft high at the back, and 5 ft to 7 ft in front, and better houses are made

of two of these mats, forming a saddle roof, with two extra posts to support it, but no walls. These huts are placed in a rough circle round the cleared dancing ground. The Bushmen of the Kalahari desert scoop out hollows in which to curl up, as in a nest, sheltered if possible by natural bushes or by brushwood covered with a skin. The leaf-roofed huts or booths of the Negroes of Central Africa are much like from the Cameroons to Sem-

BY COURTESY OF THE CANADIAN PACIFIC RAILWAYS
VILLAGE SCENE IN THE FILIPIN ISLANDS SHOWING THE STRAW THATCHED DWELLINGS OF THE NATIVES

liki valley. Sticks are bent over with both ends in the ground and roughly thatched with leaves. They are very low, with entrances barely 3 ft high, and are scarcely distinguishable in the gloom and thick foliage of the equatorial forest.

In Australia, when men are camping for a night or two, the windscreen of brushwood is sufficient, in bad weather the boughs are interlaced overhead to form a horseshoe hut, for longer residence in favoured districts where the search for food does not require constant moves, a regular framework of branches is set up, covered with sheets of bark, leaves or grass, skins, sods of earth or a plastering of clay. An Australian folk-tale (collected before 1850) describes a hut built of the bones of the emu and the kangaroo, covered with skins. To this home the hero brings the admiring heroine (or heroines) and "it was the most beautiful camp ever made" (W. Dunlop, *JAF* 1890, p. 32). In South America the natives of British Guiana, when on hunting expeditions, put up temporary shelters or *benab*s, which may be a few palm leaves laid flat one over the other with their stalks bound together and stuck into the ground, so that the natural curve of the leaf affords sufficient roof. A more pretentious *benab* is made by sticking three posts in a triangle and laying a bunch of palm leaves over the top. The Arawak and Carib tribes living in dense forests, sheltered by surrounding trees, build wall less houses, the Macusi, living in the open savannah, add walls, filling in the sides and daubing them thickly with clay to keep out the cold winds blowing from the mountains.

Eskimo Snow House—Without the snow *iglu* life in winter would be impossible for the Eskimo. The original construction was a ring of stones filled in with earth, the roof of sods being supported on branches, as is still the custom to the east and west of the Eskimo territory where wood is obtainable, but from the mouth of the MacKenzie eastward, where the supply of driftwood dwindles, snow houses are the common residence in winter and skin tents in summer. Even where there are stone and wooden houses (and wooden houses spread with Christianity), the snow *iglu* is put up for special occasions or on journeys, as it is quickly built and is impervious to weather. A man cuts a trench some 5 ft long and 20 in deep in a newly made snowdrift, where he means to place his house. From the face of the trench he cuts blocks with his bone knife. These are slightly concave so that they lean inward when set up on edge. A circle of blocks is laid and then shaved down so that the succeeding blocks form an ascending and narrowing spiral, the builder cutting the material from the inside of his house as he works. A key-stone with edges wider above than below is dropped into the space at the top, and

all cracks and crevices are filled in with soft snow. A small house can be built in a couple of hours, but for longer residence more care and time are taken, and on special occasions houses of a huge size can be built on the same plan. One erected to welcome the Stefánsson-Anderson expedition to Akulvik, it is said, near Coronation gulf, was 6 ft in height and accommodated 50 people standing up, with a circular space of about 5 ft left in the centre for the

CHARACTERISTIC DALA HOUSE OF THE FIJI ISLANDS

dancers, and festival halls 16 ft high and 70 ft across are reported from Labrador. If it is wanted for more than temporary residence, an alley way 10 ft to 20 ft long is built outside the house as a shelter for the dogs and gear, with recesses where food can be stored out of the dogs' reach. When the house has been built with the snow platforms for beds inside—this is the man's work—the housewife takes possession. She lights her blubber lamp, feeds it generously so that it burns with all possible heat, closes the door with a block of ice and makes all air-tight. The snow soon begins to melt and, owing to the curve of the domed roof, it does not drip, but soaks gradually into the blocks so that they are nearly wet through. When they are sufficiently sodden the woman puts out her lamp and opens the door. In rushes the intensely cold air, and in a few minutes the house is transformed from a fragile structure of snow that would crumble if touched carelessly, to a vaulted dome of ice so strong that a polar bear might crawl over the roof (as often happens) without the danger of breaking it in.

When the long winter is nearing its end and the temperature rises, the snow houses, however solidly built, begin to melt. The roof is the first to go, and if this caves in, an old skin can be stretched across, but the inhabitants lead an uncomfortable life until they can camp in the open in the skin tents which are their common summer dwellings. These may be merely little bits of three cornered shelters where skins are spread over the sides of a tripod leaving the lee side open, or large affairs, 6 ft by 14 ft, with a ridge pole supported on a tripod at each end, and a door in the middle of one of the long walls. Thus, like so many of the snow houses, may contain two families—one to the right and one to the left of the door.

NORTH AMERICA, OCEANIA, AFRICA

Of the three Eskimo types of dwelling, the semi underground earth house occurs down the west coast as far as San Francisco bay and is met with again in the "earth lodge" of the Missouri region, while the tent, made of skins in the bison area, of birch bark where birches abound and sometimes of moss among the Chibway (Chippewa), was the universal shelter across the centre of the continent to the barrier of the Rocky mountains. On the

west coast were the timber built houses, such as those of the Huda and Ilingit or the Coast Salish. These were built entirely of massive posts of red cedar (*Thuja plicata*), and planks split with elk horn or maple wood wedges, tied to the uprights. These houses, with almost flat roofs, often 40 ft deep and some hundreds of feet in length, stratched along the shores of river or sea. Inside they were divided by grass mats into separate family compartments, and again into "hearths" or "fire-places." In front were the totem poles carved and painted with the emblems of the occupants. Further south are the brush shelters of California, or shelters of branches, covered with grass but nothing of substantial structure is found until the Pueblo region of Arizona and New Mexico is reached. In the Rio Grande (which is also the area of the cliff dwellers) the houses are built of adobe (sun-dried bricks), wattle and daub, or stone. The Pueblo stone buildings are linked on to the earlier Nahuatl or Maya culture, for in Mexico and Peru alone was architecture developed in masonry, though neither had attained to the knowledge of the arch. The buildings were massive, and height was gained by platforms of natural or artificial mounds. Inca influence did not spread far in South America. A shelter for the hammock was sufficient in the Amazon region, though large communal thatched houses are not unknown, a skin tent is characteristic of the guanaco area, and this in the extreme south, dwindles to little more than a lean to.

In Oceania, although the huts of the indolent are poor and mean, especially in Melanesia, the abundance of timber and various palms, reeds and grasses the universal agriculture and fishing, with fairly easy life, have raised the general standard of house building to a high level. Round houses are associated with earlier culture, but for the most part houses are oblong, built either on the ground or on piles. Some of the chiefs' houses are of enormous size. One at Pare (Tahiti) was 397 ft long, and held two or three thousand people. This was rectangular with rounded ends, built by men specially trained to the craft.

African houses are easily made, whether by nomadic hunters, pastors or agriculturalists, and as easily deserted. To the south of the Sahara, unimproved save for the sun dried brick houses of the oases and the goats' hair cloth tents of the nomads, round beehive or conical huts with low entrances and thick grass thatches are typical of the plains and open country and of Bantu culture in general. In hotter, drier regions the walls are often plastered with mud. Across the centre of Africa, west of the great lakes (Wa Nyamwezi, Manyema and some of the Ba Rotse), to the west coast stretches a belt of rectangular huts, in striking contrast to the circular shapes north and south of it. This is the forest region, and the contrast has been variously attributed to (a) influence of street formation rather than kraal formation, (b) derivation from the kraal to shelter, rather than the circular tent, or (c) recent or Arab contact.

Tree houses and Pile dwellings.—The need for defence against enemies led to the construction of tree-houses, pile dwellings, crannogs, and floating islands in many different parts of the world. The need of portable shelters by wandering hunters or nomadic pastors developed the Bedouin tent, the Dakota tipi, the Mongol gher and the Khazig yurt. Similar or contrasted social conditions produced the communal houses in Africa, the East Indies, Melanesia and North and South America.

Houses built in trees are for temporary use, either as look out places or for refuge in case of attack. A platform is often built in a tall tree from which the incursions of enemies are discovered, or crops watched and guarded. More substantial structures are made as refuges in case of an enemy raid. In the inland unsettled parts of New Guinea small strongly built houses are erected in trees. They are reached by ladders, which can be pulled up when the refuge has been gained. It is by no means an easy or rapid matter to cut down a large tree with stone axes, especially when overhead foes are hurling down stones and spears. Houses are also built for defence on piles standing out of the water. A platform is laid on the piles, and huts are built on the platform. Dwellings of this type were built on the edges of lakes in prehistoric Europe, and occur on shallow shores of the sea, lakes or rivers in North and South America, Africa, the East Indian archipelago and Me-

TYPES OF PRIMITIVE DWELLINGS

- 1 Ceylon Veddha rock shelter. Caves and overhanging rocks provide shelter for jungle dwellers.
- 2 A Blackfoot camp or tipi on Two Medicine Lake, Glacier National Park, Montana. A tripod of poles against which other poles are propped is covered over with stitched skins, pegged down all around at the bottom. Occasionally birch bark is used instead of skins. A skin flap covers the entrance which usually faces the east. A hole at the top allows smoke to escape.
- 3 Hebridean shieling made of stones and turf. The floors of these dwellings are scooped out to make more head room under the low roofs.
- 4 An Andaman hut. A roof of mat screens is propped up on four posts from 2 to 4 ft high at the back and from 5 to 7 ft in front. Better huts are made by using two mats to form a saddle roof.
- 5 Pile dwellings in New Guinea. Hard wood poles, sometimes 30 ft long, are sunk at oblique and are then covered with a platform of planks upon which the huts are built.
- 6 Mount Ruwenzori, Africa. Ba Kongo hut. Bamboo sticks are bent over with both ends to the ground to be thatched later with leaves or grass.
- 7 Ba Kongo hut completed with banana leaf thatch. Note the low entrance barely 3 ft high.

lanesia Pile houses may be built on land, forming wet season houses in districts which are liable to be inundated. In the pile village of Bulia in the Rigo district of British New Guinea the piles are often 30 ft. in height, of very hard wood, with one end roughly pointed. This end is dropped into a hole at low tide by the help of several men and ropes, and the pole is swung backward and forwards until by its own weight it worms its way into the ground. Heavy planks are laid on the piles to form a platform and on this the houses are built.

Crannogs are built on natural or artificial islands formed of brushwood, logs, stones and clay. They were common in prehistoric times in Ireland, and used down to the reign of Elizabeth.

The lake village of Glastonbury was made of brushwood on layers of tree trunks, pegged down with small piles. Above was a platform of logs laid side by side, and on this was plastered clay several feet thick. The round wattle and daub huts were erected on this foundation. In the African lakes floating islands of papyrus are artificially strengthened and huts built on the top.

PORTABLE DWELLINGS

Tents—People who are constantly shifting camp, whether wandering hunters in pursuit of game or nomadic herdsmen moving their flocks to pasture, have invented portable dwellings, varying from the flimsy skin tent of the Eskimo, or the equally skimpy tent of the guanaco area of South America, to the luxurious and spacious yurt of the rich steppe lands of Asia. The Eskimo tent, the common summer residence from Alaska to Labrador, is found also in Siberia, and is perhaps linked on to the cloth covered tent of the reindeer Lapps in Scandinavia. South of the Eskimo area the typical tipi (its Dakota name) is found from northern New England throughout the Cree and Ojibway (Chippewa) country and across the bison area to north west Canada. The nucleus is a tripod of poles against which other poles are propped, and over this is stretched a cone shaped cover of stitched skins, pegged out all round. A skin curtain hangs across the entrance, which faces the rising sun, and poles on the outside regulate smoke flaps on either side of the hole at the top. In wooded areas where birches grow, sheets of bark are used as coverings, but skins are more suitable for transport. This is the ideal dwelling of nomadic peoples, it is easy to set up, easy to take down and easy to shift. The poles, tied on either side of dog or horse, drag along the ground,

MOTU COMMUNAL HOUSE OF NEW GUINEA

the cover wraps the scanty household gear in a bundle and lies across their trailing ends. The Ostiak *choom* in the lower Obi district is made of 20 or 30 thin poles fixed in a circle and fastened together at the top, covered with sheets of birch bark boiled to make them pliant, and cut with convex curves to fit over the cone shape of the framework. Extra skins may be added outside with an opening to leeward. The most luxurious tents in all Asia are those of the rich steppe lands of the centre, from the Khalka in eastern Mongolia to the Khirgiz nearing the Urals in the west. In this mainly treeless area long tent poles are not easily found, and the foundation is made of latticework hurdles (usually willow) lashed to posts firmly fixed in the ground. From these, smaller

poles radiate towards the centre. Over this framework are stretched the covers of skins or felt (threefold in winter to mitigate the intense cold). There is a hole in the centre of the roof through which the smoke from the fire of *argol* or a little dung can escape, though it is usually kept closed by a piece of felt drawn across by a string. A felt curtain, often beautifully embroidered, falls over the entrance facing south, and curtains fastened to the sides of the tent can be let down to form separate compartments. This form of tent is heavy and cumbersome, but camels, horses and cattle provide abundant beasts of burden, and the setting up and taking down of the tent is always woman's work.

A far simpler tent suffices for the hardy desert herdsmen of western Asia and north Africa. The typical Bedouin tent is of sticks, sometimes forked with a ridge pole, which irregularly supports a cover made of woven goats' hair strips sewn together, usually black from use if not by nature. The cover may be pegged down at the back or banked up with stones and sand, but it is an awning rather than a tent.

Long Houses—A great stimulus is given to house building in those primitive societies in which the house belongs not to the individual but to the clan, or where there are secret societies or men's club houses, or where it is the custom for the unmarried men or the warrior class to sleep in a separate house. These customs lead to the building of houses such as the long houses of British Columbia, the circular houses on the Putumayo, 70 ft. in diameter, holding 70 families under one roof, the long houses built of piles along the river banks in Borneo, containing 40 to 50 families, the Kiwai houses, on piles, off the New Guinea coast, two or three hundred feet in length, holding 180 people, and the men's club houses that are a conspicuous feature of Melanesian villages generally. The best of the long houses in Borneo are built by the Kayan. The piles are massive posts of iron-wood, 2½ ft. to 3 ft. high, supporting a ridge-pole roof. The floor is laid on piles 7 ft. or 8 ft. high, with cross beams mortised to these and large planks laid across, running the length of the house. The side furthest from the river is walled in, forming separate rooms, but on the river side is a long gallery, protected by the overhanging roof. This is the sleeping place for bachelors and male visitors and the place for receiving guests and carrying on the daily work, such as *padi* husking, etc. The floors of the inner rooms are of split bamboo, placed a little way apart like lattice-work, so that all rubbish falls to the ground underneath. The pigs live under the house, and this also serves as a place for storing boats. Entrance to the house is by a notched pole at one end of the verandah.

DWIGHT, JOHN (d. 1703), the first distinguished English potter. The date of his birth has been variously given from 1637 to 1640, and he died at Fulham in 1703. He took the degree of B.C.L. of Christ Church, Oxford, in 1661, and was appointed in that year registrar and scribe to the diocese of Chester. At Chester he was secretary to four successive bishops. He seems also to have resided at Wigan where three of his children were baptized between 1667 and 1671. He was granted in 1671 his first patent for the "Mystery of transparent earthenware, commonly known by the names of porcelain or china, and of stoneware, vulgarly called Cologne ware." He probably moved to Fulham about that time. His name appears on the rate books for a house in Bear street in 1674. It has been claimed, though without proof, that Dwight made the first porcelain in England. It has, however, been proved that he preceded John and David Elers in the manufacture of that fine red stoneware which these foreign potters were supposed to have first made in Great Britain. The British and Victoria and Albert Museums contain a number of his pieces, of which the finest is the bust of Prince Rupert.

See Sir A. H. Church, *The Family of John Dwight, B.C.L., Potter* (reprinted from *The Genealogist*, 1910).

DWIGHT, THEODORE WILLIAM (1821–1902), American jurist and educator, cousin of Theodore Dwight Woolsey and of Timothy Dwight, was born July 18 1822, in Catskill, New York. He graduated at Hamilton college in 1840 and studied law for one year at Yale. After tutoring at Hamilton and teaching law privately he was made Myrland professor of law, history, civil politics, and political economy in 1846, and in 1858 accepted an invitation to Columbia to teach law upon his own condition that he should found a law school. For many years he himself was the school and did not retire from it until about a year before his death in Clinton (N.Y.), on June 28 1892.

A man of broad culture, he used the Socratic method of teaching. For several years he was a non-resident professor of law at Cornell and at Amherst. An able jurist, he frequently acted as referee in difficult questions and engaged in other legal and judicial work. He was a prominent figure in political and social (notably prison) reforms. He published in 1807 a *Report on the Prisons and Reformatory of the United States and Canada* (with F. C. Winsor), favored indeterminate sentences, drew up the bill for the establishment of the Elmira Reformatory, and organized the State Charities Aid Association. He edited Sir Henry Maine's *Uncertain Law* (1804), was associate editor of the *American Law Register* and legal editor of *Johnson's Cyclopaedia*, and published *Charitable Uses: Argument in the Rose Will Case* (1803).

DWIGHT, TIMOTHY (1759–1817), American divine, writer, and educationalist, was born at Northampton (Mass.), May 14, 1752. His father, Timothy Dwight, a merchant, was a graduate of Yale, his mother, Mary, was the third daughter of Jonathan Edwards. After his graduation from Yale in 1769 he taught in a grammar school at New Haven, and he was a tutor in Yale college from 1770 to 1777, then, having been licensed to preach, he was a chaplain for a year in a revolutionary regiment. He inspired the troops by his sermons and by several war songs, the most famous of which is "Columbia." From 1778 until 1783 he lived at Northampton, studying, farming, preaching and dabbling in politics. From 1783 until 1795 he was pastor of the Congregational church at Greenfield (Conn.), where he opened an academy which at once acquired a high reputation. From 1795 until his death at Philadelphia (Penn.), Jan. 21, 1817, he was president of Yale college, and by his judicious management, by his remarkable ability as a teacher, and by his force of character he won great influence and did much to raise the standard of the college. President Dwight was also well known as an author. In verse he wrote an ambitious epic in 11 books, *The Conquest of Canaan*, virtually finished in 1774 but not published until 1785, a somewhat ponderous and solemn satire, *The Triumph of Infidelity* (1788), directed against Hume, Voltaire and others, *Greenfield Hill* (1794), and a number of minor poems and hymns. Many of his sermons were published posthumously in *Theology Explained and Defended* (5 vol., 1819–19), to which a memoir of the author by his two sons, W. T. and Sereno E. Dwight, is prefixed, and in *Sermons by Timothy Dwight* (2 vols., 1828), which had a large circulation. Probably his most important work, however, is his *Travels in New England and New York* (4 vols., 1821–22), which contains much material of value concerning social and economic New England and New York during the period 1769–1817.

His fifth son, SERENO EDWARDS DWIGHT (1786–1850), born in Greenfield (Conn.), graduated at Yale in 1803, was a tutor there, a lawyer, a preacher and president of Hamilton college, Clinton, New York. His publications include *Life and Works of Jonathan Edwards* (10 vol., 1850), *The Hebrew Life* (1836), and *Sermons* (1851), to which was prefixed a biographic sketch by his brother, William Dwight (1795–1865), who was also successively a lawyer and a Congregational preacher.

President Dwight's grandson, TIMOTHY DWIGHT (1828–1916), preacher and educationalist, was born at Norwich (Conn.), Nov. 16, 1828. Educated at Yale, Bonn and Berlin he was professor in the Yale Divinity school from 1858 to 1886, was licensed to preach in 1861 and from 1886 to 1900 was president of Yale, which during his administration greatly prospered. Dr. Dwight was also a member in 1877–85 of the American committee for the revision

of the English Bible, was an editor from 1866 to 1874 of the *New Englander*, which corresponded to the *Yale Review*, and in addition to his translating and editorial work he published numerous magazine articles and a collection of sermons, *Thoughts of and for the Inner Life* (1800).

For the elder Timothy Dwight, see W. B. Sprague's "Life of Timothy Dwight" in vol. iv and series of Jared Sparks's *Library of American Biography*, also, "A Great College President," *West Hill*, written by M. C. Tyler's *Three Men of Letters* (1807). For the younger Timothy Dwight, see *Timothy Dwight: Memorial Addresses* issued by Yale university, 180, for a full record of his scholastic life, see his *Memoirs of Yale Life and Men, 1819–1869* (1903).

DYCE, ALEXANDER (1798–1869), British dramatic editor and literary historian was born in Edinburgh on June 30 1798. He was educated at Edinburgh high school and Exeter college, Oxford. He took holy orders and became a curate at Longleaves in Cornwall, and subsequently at Nisland, in Suffolk. In 1817 he settled in London. His first books were *Select Translations from Quintus Smyrnaeus* (1821), an edition of Collins (1827) and *Specimens of British Poetasters* (1825). He issued annotated editions of George Peele, Robert Greene, John Webster, Thomas Middleton, Marlowe and Beaumont and Fletcher, with lives of the authors and much illustrative matter. He completed in 1825, an edition of James Shirley left unfinished by William Gifford and contributed biographies of Shakespeare, Pope, Akenside and Beattie to Pickering's Aldine poets. He also edited (1826–38) Richard Bentley's works and *Specimens of British Novels* (1831). He carefully revised edition of John Stokton which appeared in 1833, did much to increase interest in that trenchant satirist. In 1837 his edition of Shakespeare was published by Moxon, and the second edition, much improved, was issued by Chapman and Hall in 1866. He also published *Remarks on Collier's and Knight's Editions of Shakespeare* (1834), *A Few Notes on Shakespeare* (1853), and *Structure on Collier's New Edition of Shakespeare* (1859), a contribution to the Collier controversy (see COLIER, JOHN PAVNE), which ended a long friendship. He undertook the publication of Kempe's *Nine Days Wonder* for the Camden society, and the old plays of *Timon* and *Sir Thomas More* were published by him for the Shakespeare society. He was associated with Halliwell-Phillips, John Payne Collier and Thomas Wright as one of the founders of the Percy society, for publishing old English poetry. Dyce also wrote *Revolutions of the Table Talk of Samuel Rayns* (1856). He died on May 15, 1869. He bequeathed his valuable library, containing many rare Elizabethan books, to the South Kensington museum.

DYCE, WILLIAM (1806–1904), Scottish printer and pioneer state art education, was born at Aberdeen on Sept. 19 1806. At 16 he graduated M.A. at Marischal college, Aberdeen, but later studied at the Royal Scottish academy, Edinburgh, and the Royal Academy schools, London. One of the first British students of early Italian painting, he visited Italy in 1825 and 1827–28 meeting in Rome the German Nazarene (pre-Raphaelite) painters. He exhibited regularly at the Royal academy, being elected A.R.A. in 1844 and R.A. in 1845. In 1830–37 in Edinburgh he practised portraiture for a livelihood, using a direct technique traceable to that of Sir Henry Raeburn. But his Italian studies led him, anticipating the English pre-Raphaelites, to a primitivist simplicity and repose in his painting. Impressed also with the important use of a basic relationship between painting and architecture and design he became deeply interested in art education. In 1840 he was appointed secretary and director of the new government school of design at Somerset house, London, and, although he largely failed to influence manufacturers' patterns, his organization of the training of teachers of design was important. Successful in the house of parliament fresco competition (1844) he painted the "Baptism of Libanus" in the house of lords (1845) and the "King Arthur" series (1848 ff., unfinished) in the queen's robing room. For the prince consort he undertook frescoes at Osborne (the "Neptune") and in the Buckingham palace summerhouse, he decorated the church of All Saints, Margaret Street, London, to the specification of the Anglo-Catholic Cambridge Camden society, in a more consciously primitive style (1858–59). Typical of his early portraits is the child study "Contentment" (Maconochie Welwood collection, R.A. 1832), later cast pictures include "Pegwell Bay" (National gallery, London, R.A. 1869) and "George Heriot" (Guildhall, London, R.A. 1861). Dyce died at Streatham, Surrey Feb. 14, 1869.

DYEING The art of colouring textile and other materials in such a way that the colour appears to be a property of the dyed material and not a superficial effect such as that produced by painting. The result of a dyeing operation may be regarded as satisfactory and the substance can be truly termed dyed when the colour is not removed by rubbing or washing or by the action of light. Comparatively few colours pass all tests to these influences, other types of fastness such as resistance to perspiration, street mud, bleaching and finishing are frequently required, and dyeings are approved if they meet some specific demand. A coloured effect, which is comparatively slight considering the amount of colour required to produce it, is regarded by the dyer as a worthless stain. Such stains are produced by dipping fabrics in the aqueous extracts of many fruits and flowers. It is natural to suppose that a desire to transfer the beautiful colours of these substances to textile fabrics may have been the origin of dyeing, but the art is such an ancient one that this is mere conjecture.

Fabrics found in the tombs of Egypt prove that those who dyed them must have been expert in the application of substances which do not immediately reveal their colouring power, but must be associated with other products in a manner which admits of variation only within well defined limits. The dyeing of red with madder or some allied product and of blue with indigo are processes which appear to have been familiar to the people of India, China, Persia and Egypt several thousand years before the Christian era. Some information regarding the dyeing processes used was evidently communicated to Europeans by Phoenicians and Alexandrian merchants, but possibly owing to the state of barbarism which followed the civilizations of Greece and Rome records of the methods practised by these people are very scarce. Pliny gives a description of the dyeing of Tyrian purple and some other colours. In the early period of its development dyeing was probably a home industry carried on mainly by women.

In the 13th century there was a notable revival in the art, for a Florentine named Fedeigo discovered how to prepare and use certain lichens found in Asia Minor for the dyeing of purple. For this he was awarded great honour and the privilege of adopting the family name *Rucella*. (The lichen he used was *Rocella tinctoria*.) In 1420 the first European book on dyeing was published at Venice, *Mariegola dell'arte de tinctori*. After that time knowledge of the subject spread to Germany, France and Flanders, from which latter country the English king Edward III. procured dyestuffs for England and a Dyers' Company was incorporated in 1473 in London.

The discovery of America in 1492 and the opening up of the Cape route to the East Indies resulted in new products (dyewoods) and new methods of dyeing being used in Europe. In 1518 the Spaniards imported cochineal from Mexico where they had observed the natives employing the insects for dyeing. It is of interest to note that the Incas were skilled in the art of dyeing, but how they acquired the knowledge is unknown. In 1630 a Dutchman named Drebbel discovered how to obtain a brilliant scarlet on wool with tin and cochineal. The process was communicated to other dyers, and the new scarlet was dyed as a specialty at the Gobelins works in Paris, and, in 1643, at a dyeworks at Bow, near London.

On the initiative of the Royal Society, the first English book on dyeing entitled *An apparatus to the history of the common practices of dyeing* was published in 1662. In France much attention was given to the promotion of the art by the various ministers of State. Colbert published a code of instructions to wool dyers and manufacturers, but the greatest service was rendered by a number of eminent chemists who investigated the processes in vogue and attempted to explain and improve them. In different ways Dufay, Hellot, Macquer, Berthollet, Roard and Chevreul in France, and Henry, Home and Bancroft in England did much to improve the methods of dyeing and to establish the industry on a more systematic basis. During this period (1700-1825) a number of important chemical products were introduced and prejudice against the use of dyewoods was overcome. It was not until the middle of the 19th century that dyers began to

consider the possibility of using coal-tar products for their work. In 1856 the first colour made from coal tar dyed wool and silk directly but could not be applied to cotton until Perkin and Pullar devised the method of tanning and fixing the tannic acid with tartar emetic, before immersing the cotton in the colour solution.

As early as 1834 Runge had conceived the idea of producing colour on the fibre by the oxidation of aniline, but it was the Accrington chemist Lightfoot who, in 1859, discovered the catalytic action of copper, in using sodium chlorate to oxidize aniline on cotton fabric, and produced a black by this method. The method of dyeing cotton with a solution of colour in sodium sulphide was introduced with the colour *cricou de Laval* in 1873 by Croissant and Bietonniere.

The substitution of naturally occurring substances used in indigo dyeing commenced about the middle of the 18th century with the introduction of ferrous sulphate (copperas) and lime. In 1845 the zinc-lime vat was first used, and for many years it was the most important vat for dyeing cotton. It reduced the loss of indigo from 20 to 10%, and the time occupied in waiting for the sediment formed in the copperas vat to settle was saved, the zinc vat clearing quickly. A product of outstanding importance is sodium hydrosulphite discovered in 1868 by Schützenberger and Lalonde. Its use was suggested by these chemists in 1872, but it was some time before any extensive use was made of the discovery. Some dyers prepared calcium hydrosulphite in solution for themselves, with sodium bisulphite, zinc dust and lime, but in 1897 the Badische Anilin und Soda Fabrik offered to dyers a commercial product which produced a clear solution of indigo where in the presence of alkali without sediment. This was improved by the solid white anhydrous sodium hydrosulphite, which was put on the market in 1903. Hydrosulphite, as the product is generally called, is extensively employed in the dyeing of vat colours. It might be dispensed with, if colours of the indigol (1922) and soledon jade green type were less expensive.

One of the most interesting and valuable dyeing processes was discovered in 1880 by R. Holliday. This was the formation of para nitramine red on cotton, a process which soon achieved great importance and formed a basis for the production of a range of allied colours on cotton (insoluble azo colours). Dyeing by this method has been greatly assisted by the introduction of the intermediate products such as Naphthol AS (1912), which yields faster colours. The rapid fast colours are admixtures of this with stabilized diazo compounds. These can be applied directly to cotton and produce the colour on the fibre by steeping in hot dilute acetic acid.

It is to Mercer and Greenwood that we owe the discovery of the effect of sulphuric acid on oils in producing more satisfactory results in turkey red dyeing than could be obtained with the oil emulsions. Turkey red oil, sulphated oil and allied products have found extended application in dyeing since the introduction of acetate silk. The study of their influence on the fastness of dyed colours is important. J. R. Hannay and F. W. A. Ermen have contributed to this knowledge concerning sulphur and vat colours respectively.

General Principles.—The art of dyeing is a branch of applied chemistry in which the dyer is continually making use of chemical and physical principles in order to bring about a permanent union between the material to be dyed and the colouring matter applied. If cotton or wool is boiled in water containing finely powdered charcoal, or other insoluble coloured powder, the material is not dyed, but merely soiled or stained. This staining is entirely due to the entanglement of the coloured powder on the rough surface of the fibre, and a vigorous washing and rubbing suffices to remove all but mere traces of the colour.

There must always be some marked physical or chemical affinity existing between fibre and colouring matter, and this depends upon the physical and chemical properties of both. It is well known that the typical fibres, wool, silk and cotton, behave very differently towards the solution of any given colouring matter, and that the method of dyeing employed varies with each fibre. As a general rule wool has the greatest attraction for

colouring matters and dyes most readily, cotton has much less attraction, while silk occupies in this respect an intermediate position. These differences may be to some extent due to differences of physical structure in the fibres, but they are mainly due to their different chemical composition. Many processes and treatments to which textile fibres are subjected yield materials which show very different dyeing properties from the original substance.

Dyeing processes may be classified under the following headings—

- I Direct dyeing, using,
 - (1) Basic colours for animal fibres and acetic acid silk
 - (2) Acid colours for wool
 - (3) Direct cotton colours for both vegetable and animal fibres
- II Dyeing with reduced colour solutions in
 - (1) Sulphur colours
 - (2) Vat colours
- III Mordanting and dyeing, using,
 - (1) Basic colours for cotton
 - (2) Mordanting, with metallic compounds and dyeing
- IV Producing colours on the fibre. Mainly used for vegetable fibres
 - (1) Aniline black
 - (2) Insoluble vat colours
 - (3) Mineral colours

Direct Dyeing.—This is the simplest of all dyeing operations. It is most successful in the case of animal fibres, wool showing such a decided affinity for both acidic and basic organic compounds which possess colouring power that a very numerous selection of colouring matters is possible.

(1) Wool is dyed with basic colours directly from a neutral aqueous solution (without additions) the wool combining with the colour base to form a coloured salt or lake on the fibre. Although a neutral dyebath may be employed, an addition of 2% soap gives a brighter colour and in some cases acid is added to the bath. Silk is dyed in a bath containing boiled off liquor, 2 to 3% on the weight of material is usually necessary.

Acetate silk has such a remarkable affinity for organic compounds of a basic character that it is capable of combining with these under a variety of circumstances. The basic colours act as direct dyes for acetate silk and some (brilliant green, for example) show better fastness on it than they do on tanned cotton. Amino azo and insoluble basic dyes converted into their carboxylic acids dye acetate silk. The compounds of insoluble organic bases with the omega sulphonic acid group ($\text{C}_6\text{H}_4\text{OH SO}_3\text{H}$) are soluble colours, ionamines, which dye acetate silk in the presence of formic or sulphuric acid. Some can be diazotized and developed on the fibre.

Insoluble basic compounds in a dispersed or colloidal condition with sulpho ricinoleic acid (soluble oils) dye acetate silk direct at 80°C (SRA colours). Other colours employed in this way are amino anthraquinone derivatives (duranol, celatene and dispersol colours).

(2) The acid colours are applied to wool in this way because it is necessary to modify the composition of the fibre to render it capable of uniting with the colour and of the dyestuff. Wool boiled with dilute sulphuric acid and then thoroughly washed with boiling water until free from acid acquires the property of dyeing with acid colours even in neutral solution. The amount of colour used is from 4 to 6% on the weight of the wool with 2 to 5% sulphuric acid (1.84 sp. gr.) and 10% sodium sulphate (Glauber's salt). The last addition is made to produce level dyeing, it exerts a restraining action. This is also effected by the use of old dye liquors, a diminished amount of acid, the employment of weaker acids, acetic or formic acid or ammonium acetate and entering the material at a low temperature.

The woollen material is introduced and continually handled or moved about in the solution while the temperature of the latter is gradually raised to the boiling point in the course of $\frac{1}{2}$ to 1 hour, after boiling for $\frac{1}{2}$ to 1 hour longer, the operation is complete, and the material is washed and dried.

In the application of alkali blue the process of dyeing in an

acid bath is impossible, owing to the insolubility of the colour in an acid solution. Wool and silk, however, possess an affinity for the alkali salt of the colouring matter in neutral or alkaline solution, hence these fibres are dyed with the addition of about 5% borax, the material acquires only a pale colour, that of the alkali salt, in this dyebath, but by pressing the washed material into a cold or tepid dilute solution of sulphuric acid a full bright blue colour is developed, due to the liberation of the colour acid within the fibre. In the case of other acid colours, e.g., chromotrope, chrome brown, chromogen, alizarin yellow, etc. the dyeing in an acid bath is followed by a treatment with a boiling solution of bichromate of potash, alum or chromium fluoride, whereby the colouring matter on the fibre is changed into insoluble oxidation products or colour lakes. This operation of developing or fixing the colour is effected either in the same bath at the completion of the dyeing operation, or in a separate bath.

When dyeing with certain acid colours, e.g., eosine, phloxine and other allied bright pink colouring matters derived from resorcin, the use of sulphuric acid as an assistant must be avoided, since the colours would thereby be rendered paler and duller, and only acetic acid must be employed.

The properties of the dyes obtained with the acid colours are extremely varied. Many are fugitive to light, on the other hand, many are satisfactorily fast, some even being very fast in this respect. As a rule, they do not withstand the operations of milling and scouring very well, hence acid colours are generally unsuitable for tweed yarns or for loose wool. They are largely employed, however, in dyeing other varieties of woollen yarn, silk yarn, union fabrics, dress materials, leather, etc. Previous to the discovery of the coal tar colours very few acid colours were known, the most important one being indigo extract. Prussian blue is applied to wool may also be regarded as belonging to this class, also the purple natural dyestuff, orchil or cudbear. Xyldine scarlet, discovered in 1879, was the first synthetic colouring matter of this class, which comprises such members as picric acid, tartrazine, orange II, fast acid violet, lissamine fast yellow and orange, alphanol, cyanol, lanacyl, luteon and neonol colours. The last compounds contain copper and chromium and are therefore mordant colours which can be dyed direct on wool from an acid bath. They are fast to milling.

(3) Direct cotton colours may be regarded as a particular type of acid colours because wool and silk dye in the presence of acetic acid, but they are characterized by the fact that cotton shows a decided affinity for them. At the same time cotton does not show that complete absorption of colour which is characteristic of wool and merely absorbs a portion of the colour from the bath, in amount depending very much upon the concentration of the dye liquor. The first colouring matter of the class was the so-called congo red discovered in 1884. Since that time a very great number have been introduced which yield almost every variety of colour. The method of dyeing cotton consists in merely boiling the material in a solution of the dyestuff, when the cotton absorbs and retains the colouring matter by reason of a special natural affinity. The concentration of the dyebath is of the greatest importance, since the amount of colour taken up by the fibre is in an inverse ratio to the amount of dye liquor present in the bath. The addition of 1 to 3 oz. sodium sulphate and $\frac{1}{2}$ to $\frac{3}{4}$ oz. carbonate of soda per gallon gives deeper colours, since it diminishes the solubility of the colouring matter in the water and increases the affinity of the cotton for the colouring matter. An excess of sodium sulphate is to be avoided, otherwise precipitation of the colouring matter and imperfect dyeing result. With many dyestuffs, it is preferable to use $\frac{1}{2}$ to $\frac{3}{4}$ oz. soap instead of soda. On cotton the dyed colours are usually not very fast to light, and some are sensitive to alkali or to acid, but their most serious defect is that they are not fast to washing, the colour tending to run and stain neighbouring fibres. Wool and silk are dyed with the direct colours either neutral or with the addition of a little acetic acid to the dyebath. On these fibres the dyed colours are usually faster than on cotton to washing, milling and light, some are fast even to light, e.g., diamine fast red, chrysopemine, hessian

yellow, etc. many of the direct colours are very useful for dyeing plain shirtings on union fabrics composed of wool and cotton, silk and cotton, or wool and silk. Owing to the facility of their application, they are also very suitable for use as household dyes, especially for cotton goods. Colours of this type are benzo purpurine, benzo fast violet, chlorazol and dianol colours. The fastness may be improved by after treatment, (a) diazotizing and developing, (b) formaldehyde treatment and (c) after treatment with metallic salts. (a) Applies to colours such as primuline which contain a free amido group and can be passed through a bath of sodium nitrite and hydrochloric acid and afterwards through a solution of an amino compound or phenol. Primuline yellow is converted into a red by this treatment. In some cases the colour change is not so marked, but the colours are distinctly improved in fastness to washing. (b) The treatment with formaldehyde applies to the benzoform colours and it improves the fastness to washing. It is carried out at about 70°C with an aqueous solution. Treatment with boiling copper sulphate (0.5%) increases the light fastness.

Different batches of viscose silk show considerable variation in affinity for the direct cotton colours. In some cases colours appear distinctly light in shade on one batch and dark on another batch of viscose, so that defects may appear in manufactured articles which happen to contain the two types of viscose. What taker has shown that this trouble may be overcome by the careful selection of colours which show low capillarity, or in the case of shades composed of mixtures of colours by making these up from colours of nearly the same capillary properties. The icy colours do not show conspicuous differences when dyed on different batches of viscose silk.

So many colours have been introduced for the direct dyeing of acetate silk that methods of treating the fibre in order to impart to it an affinity (which it does not show in the ordinary condition) for direct cotton colours have comparatively little interest. The hydrolyzing or saponifying action of alkali, if cautiously applied to the silk, does not reduce its lustre but may result in loss of weight and strength. This treatment and the action of ammonium thiocyanate impart to acetate silk some affinity for direct cotton colours.

Immunized cotton, that is cotton first converted into alkali cellulose and then treated with toluol sulphonic chloride or allied compounds, shows no affinity for direct colours. The process of immunizing may be applied to yarn or piece goods either wholly or locally. Esterified cotton has somewhat similar properties.

Dyeing with Reduced Colour Solutions.—Many insoluble coloured substances form soluble reduction products which show a definite affinity for fibres. Characteristic in this respect are (1) sulphur colours which dissolve in sodium sulphide and (2) vat colours which react with sodium hydrosulphite and other reducing agents in a somewhat similar way. These colours are most easily applied to vegetable fibres because the solution is invariably alkaline and special devices have to be employed in the case of wool. As a rule it is generally found preferable to use direct dyeing acid and mordant colours for wool, but a number of preparations have been put on the market to protect wool from the injurious action of alkali in dyeing sulphur and vat colours.

(1) Sulphur colours. The material is heated for about one hour in a solution of the colour (10 to 15%), with the addition of sodium carbonate (1 to 10%), common salt (10 to 20%) and sodium sulphide (5 to 30%), it is then washed in water and may be developed by heating in a bath containing 2 to 5% of bichromate of soda, and 3 to 6% acetic acid. A final washing with water containing a little soda to remove acidity is advisable. The sulphide colours are remarkable for their fastness to light, alkalis, acids and washing, but unless proper care is exercised the cotton is apt to be tendered on being stored for some time. This is particularly noticeable in the case of blacks and to some extent with yellow sulphur colours. The cause of tendering has been the subject of much research. Zanker (1914) considers it to be due to the oxidation of sulphur in chemical combination with the dyestuff. Most workers agree that the tendering is due to the formation of acid. Holden's method of overcoming the tender

ing is probably the most efficient. It consists in impregnating the cotton with tannic acid, and then passing through lime water before dyeing in the sulphur colour. The tannic acid or formaldehyde provides an insoluble and powerful base present on the fibre and combined only with the tannic acid. Sulphur colours are suitable for dyeing goods which are intended for rubber proofing.

Some kinds of finishing materials affect the fastness of sulphur colours very materially. Hannay (1912) has shown that castor oil preparations (soluble oil, monopal soap) very materially reduced the light-fastness of sulphur colours.

(2) Vat dyeing is one of the oldest dyeing processes naturally occurring substances being used for the production of fermentation vats for the dyeing of indigo blue. In the early days of dyeing in England and as soon as dyes were by law permitted to use indigo in place of woad, vats were prepared from woad, bran, madder and wood ashes. These substances were used for wool dyeing long after chemical reagents had been suggested and introduced for cotton dyeing. Practically any substance or mixture of substances capable of producing hydrogen in an alkaline medium will reduce indigo. The reduction product, leuco indigo or indigo white, dissolves in the alkali with a yellow colour. In the fermentation vat, butyric acid fermentation is induced in the bran and madder by the ferment contained in woad and hydrogen is formed. Wood ashes or lime provide the alkali necessary for the solution of the indigo white. Other vats which have found application in dyeing are the copperas and lime zinc-lime, bisulphite-zinc lime, and the sodium hydrosulphite vats. The last is the most important, it produces a vat free from sediment and little loss of indigo. It is usual to prepare a stock vat and then to add some of this to a large volume of water (1,000 gals) from which the dissolved oxygen has been removed by adding a little sodium hydrosulphite (9½ ozs) and caustic soda (½ pint 76°Tw). The stock vat may be made suitable for cotton by mixing 100 lb indigo (20% paste) with 10 gals warm water and 5½ gals caustic soda 76°Tw, heating to 40–50°C and adding about 20 lb sodium hydrosulphite. Dyeing is carried out by dipping cotton in the cold vat for a few minutes, and darker shades are obtained by repeated dipping alternated with exposure to air. Washing with cold water assists the oxidation of the leuco compound. In dyeing wool, the amount of alkali in the vat must be strictly limited. Substances such as protectol or the sulphite pulp waste liquor from paper manufacture and glue are recommended for use in wool dyeing with vat colours to protect the fibre from the injurious action of alkali. In wool dyeing a temperature not lower than 70°C is required for the dyeing of other vat colours and in all cases the time of dyeing for wool is longer than for cotton. Wool requires ½ to 2 hours for the dyeing of indigo. It is now difficult to buy suiting dyed with indigo, for the shirde is generally imitated with acid chrome colours and with other acid (wool) colours.

The leuco compounds of the anthraquinone colours are usually less soluble than those of the indigoid colours and require more caustic soda to produce a vat. The amount of alkali has frequently to be double the quantity used for indigo, so they are difficult to apply to wool. Indanthrene blue is a colour of remarkable fastness, but unfortunately this cannot be said of all members of the series of colours of which this is the type. Cibacron yellow fades on exposure to light and at the same time the fibre is considerably tendered. In connection with colours of this type it has been noticed by F. Scholefield that if light is allowed to fall on the vat, the shades appear brighter than those developed in the dark but the fabric becomes tender in a few minutes and other colours that may be dyed in the same vat are destroyed.

The production of a vat is always accompanied by chemical change, which is shown by the formation of solution and frequently by colour change, but this is not so in the case of indanthrene which merely forms a vat of different shade of blue to that of the deoction of colour and water. Indanthrene yellow produces a blue vat, thio indigo red gives a yellow vat.

The indigosols and corresponding anthraquinone products (sole dion colours) are vat colours presented to the dyer in an already reduced condition. They are applied like acid dyes to wool and silk and are mixed with a solution of sodium nitrite and padded on cotton. Various acid oxidizing agents may be used for developing the colours on wool and treatment with acid to react with the sodium nitrite in the case of cotton. They may be developed in other ways, one of the most interesting being that of staining cotton dyed with chloride of soda, vanadium chloride, neutral ammonium oxalate and indigosol O which resembles a process of producing aniline black. This renders possible the production of different colours side by side and is most valuable from the point of view of colour printing. Colours include duran-throne, digol, cibri, besides those already mentioned.

Mordanting and Dyeing.—(1) Basic colours applied to cotton. Unlike the animal fibres cotton has little affinity for the basic colours. It is usual to deposit tannic acid on the fibre in the form of an insoluble tannate. For this purpose pieces are steeped in a solution containing 2 to 6 oz. per gallon tannic acid and after being evenly squeezed are passed through a warm solution of tartaric or other salt of antimony or tin. The tannic acid has the power of combining with the base of the colouring matter in the subsequent dyeing operation, which is generally carried out with 1-2% colour on the weight of cotton to be dyed and sufficient water, in the cold or if the temperature is raised at all it is best not higher than 70°C. The basic colours are moderately fast to soap, but most of them are very loose to light. Methylene blue is one of the best in this respect. The first colour (or colour) may be dyed in this way, which is especially remarkable for brilliance and high colouring power. One natural colour which has long been known to dye in this way is the burberry, which contains the alkaloid berberrine, but in 1918 Everest showed that the flower colours (antho-cyanines) could be dyed on tanned cotton. They are fast to light but loose to soap, and in respect to these properties are therefore quite different from the synthetic colours dyed in this way. In the dyeing of basic colours, tannic acid may be substituted by katalon (a phenolic compound containing sulphur) which can be applied in alkaline solution and in presence of salt. It does not require fixing but appears to have some affinity for cotton which is rather like that of direct colours. Direct cotton, sulphur and vat colours will act as mordants for basic colours forming lakes on the fibre.

Some important basic colours are rhodamine, brilliant green, auramine and methyl violet. A dyestuff astrifloxane has been offered as a substitute for rhodamine.

(2) Mordanting with metallic compounds and dyeing. The deposition and fixation of metallic oxides or basic salts of certain metals on vegetable and animal fibres is a necessary feature of the production of colour in the case of certain organic compounds such as alizarine and haemateine which may be termed colour principles. Colour principles are the essential constituents as far as dyeing is concerned of many woods and other natural products which have found considerable application, consequently mordanting operations have been of great interest to dyers. The method provides some dyings of great fastness. The animal fibres are very easily mordanted. For example, wool boiled for 1 to 1½ hours with 2-3% potassium bichromate absorbs chromic acid and reduces it to chromium chromate tinting the fibre a pale olive yellow. On subsequent dyeing the chromium chromate is reduced to chromium hydrate by a portion of the dyestuff and this result can with advantage be obtained previous to dyeing by the use of assistants such as sulphuric acid, cream of tartar, tartaric acid, lactic acid, etc. For special purposes chromium fluoride, chromium alum, etc., are employed. Alum or aluminium sulphate (8%), along with acid potassium tartrate (cream of tartar) (7%), is used for brighter colours—e.g., reds, yellows, etc. The object of the tartar is to retard the mordanting process and ensure the penetration of the wool by the mordant, by preventing superficial precipitation through the action of ammonia liberated from the wool; it ensures the ultimate production of clear bright, full colour. For still brighter colours, notably yellow and red, stannous chloride was at one time largely employed, but it is used

less frequently, and the same may be said of copper and ferrous sulphate, which were used for dark colours. Silk may be often mordanted in the same manner as wool, but as a rule it is treated like cotton. The silk is steeped for several hours in cold neutral or basic solutions of chromium chloride, alum, ferric sulphate, etc., then rinsed in water slightly, and passed into a cold dilute solution of silicate of soda, in order to fix the mordants on the fibre as insoluble silicates. Cotton does not, like wool and silk, possess the property of decomposing metallic salts, hence the methods of mordanting this fibre are more complex and vary according to the metallic salts and colouring matters employed, as well as the particular effects to be obtained. One method is to impregnate the cotton with a solution of so-called sulphated oil or turkey red oil, the oil prepared material is then dried and passed into a cold solution of some metallic salt—e.g., aluminium acetate, basic chromium chloride, etc. The mordant is thus fixed on the fibre as a metallic oleate, and after a passing through water containing a little chalk or silicate of soda to remove acidity, and a final rinsing, the cotton is ready for dyeing. Another method of mordanting cotton is to fix the metallic salt on the fibre as a tannate instead of an oleate. This is effected by first steeping the cotton in a cold solution of tannic acid or in a cold decoction of some tannin matter, e.g., sumach, in which operation the cotton attracts a considerable amount of tannic acid, after squeezing, the material is steeped for an hour or more in a solution of the metallic salt, and finally washed. The mordants employed in this case are various—e.g., basic aluminium or ferric sulphate, basic chromium chloride, stannic chloride (cotton spirits), etc. There are other methods of mordanting cotton besides those mentioned, but the main object in all cases is to fix an insoluble metallic compound on the fibre. It is interesting to note that whether the metallic oxide is united with the substance of the fibre, as in the case of wool and silk, or precipitated as a tannate, oleate, silicate, etc., as in the case of cotton or silk, it still has the power of combining with the colouring matter in the dyebath to form the coloured lake or dye on the material.

The dyeing operation consists in working the mordanted material in a decoction of the necessary colouring matter, the dyebath being gradually raised to the boiling point. With many colouring matters, e.g., with alizarin, it is necessary to add a small percentage of calcium acetate to the dyebath, and also acetic acid if wool is being dyed. In wool dyeing, also, the mordanting operation may follow that of dyeing instead of preceding it in which case the boiling of the wool with dyestuff is termed "stuffing," and the subsequent developing of the colour by applying the mordant is termed "saddening," since this method in the past has usually been carried out with iron and copper mordants, which give dull or sad colours. The method of "stuffing and saddening" may, however, be carried out with other mordants, even for the production of bright colours, and it is now frequently employed with certain alizarin dyestuffs for the production of pale shades which require to be very even and regular in colour. There is still another method of applying mordant colours in wool dyeing, in which the dyestuff and the mordant are applied simultaneously from the beginning, it is called the single bath method. This process has become of greater interest, copper and chromium (chromium oxalate or "chromosul") being used in conjunction with acid azo colours. Some colouring matters which contain copper or chromium in combination are soluble in water and are applied like acid colours (Neolan colours).

Deposition of tannate of iron on and in the fibre is the method used for the dyeing of logwood on cotton. Logwood still finds use for the production of black both on cotton and wool. In the case of wool it is dyed on chrome mordant. Acetate silk may be dyed black (Bedford's patent) by treating first with logwood extract (haemateine) and afterwards adding borax and nitrate of iron.

For dyeing turkey-red, cotton is boiled but not bleached. After boiling, mordanting with red liquor (4° Tw) and ageing, fixing with phosphate or silicate or arsenite of soda (0.5% solution) follows. Dyeing is carried out at the boil with 10% alizarine paste, and the goods are afterwards soaped and cleared (using a little

stannous chloride) Steaming improves the colour

Interest in mordant dyeing on cotton is diminishing considerably with the introduction of colours which are more readily applied and can compete well with the fastest mordant colour alizarine or turkey red in point of fastness

Cutch is a natural colour which is still very largely used in dyeing Sailors believe that this colour protects the fabric of fish

FIG 1—WOOL DYEING IN THE BOX SYSTEM A REVERSIBLE PUMP FORCES DYE LIQUOR THROUGH THE BOX IN THE DIRECTION INDICATED

ing nets from the action of light and air It is dyed with copper sulphate in the bath but contains in addition to the mordant colour principle (catechin), a kind of tannic acid (catechu tannic acid), consequently this colour can be topped with basic colours

Colours Produced on the Fibre—(1) Aniline black is produced in situ upon the fibre by the oxidation of aniline It is chiefly used for cotton, also for silk and cotton (silk union) fabrics, but seldom or not at all for wool Properly applied, this colour is one of the most permanent to light and other influences with which we are acquainted One method of dyeing cotton is to work the material for about two hours in a cold solution containing aniline (10 parts), hydrochloric acid (20 parts), bichromate of potash (20 parts), sulphuric acid (20 parts), and ferrous sulphate (10 parts) The ferrous sulphate here employed is oxidized by the chromic acid to a ferric salt, which serves as a carrier of oxygen to the aniline This method of dyeing is easily carried out, and it gives a good black, but since much of the colouring matter is precipitated on the fibre superficially as well as in the bath itself, the colour has the defect of rubbing off Another method is to impregnate the cotton with a solution containing aniline hydrochloride (35 parts), neutralized with addition of a little aniline oil, copper sulphate (1.6 part), sodium chlorate (10 parts), ammonium chloride (1 part) Another mixture is 1.8 part aniline salt, 12 parts potassium ferrocyanide, 200 parts water, 3.5 parts of potassium chlorate dissolved in water After squeezing, the material is passed through a special oxidation chamber, the air of which is heated to about 50°C and also supplied with moisture This oxidizing or ageing is continuous, the material passing into the chamber at one end in a colourless condition, after about 20 minutes passing out again with the black fully developed A final treatment with hot potassium bichromate and soaping is necessary to complete the process In this method probably chlorate of copper is formed and this being a very unstable compound, readily decomposes and the aniline is oxidized by the liberated chlor oxygen compounds The presence in the mixture of a metallic salt is very important in aiding the development of the black (Lightfoot's observation) Salts of vanadium and cerium may be substituted for copper In the after-chroming process, chromium is fixed on the fibre and in all methods some mineral substance is fixed, chromium in the dyed black and iron in the prussiate black The organic compound on the fibre is produced by oxidation which proceeds in four stages to nigraniline and the condensation of this substance with aniline At the end of the ageing process there should be some unchanged aniline to condense and produce an ungreenable black in the chroming process On the fibre, chromate of nigraniline may be formed There is still much material for further investi-

gation especially concerning the prussiate black One of the serious disadvantages of aniline black is the liability to tender the cotton It is by no means certain whether this is due to oxidation of the cellulose or to the action of acid upon it during ageing The latter is probable, for subacids which prevent drying during ageing also prevent tendering

(2) The insoluble azo colours are produced as insoluble coloured precipitates by adding a solution of a diazo compound to an alkaline solution of a phenol, or to an acid solution of an amido compound The necessary diazo compound is prepared by allowing a solution containing nitrous acid to act upon a solution of a primary aromatic amine It is usually desirable to keep the solutions cool with ice, owing to the unstable nature of the diazo compounds produced (Products can be obtained which are stable and only decompose on acidifying) The colour obtained varies according to the particular diazo compound, as well as the amine or phenol employed, β naphthol being the most useful among the latter The same coloured precipitates are produced upon the cotton fibre if the material is first impregnated with an alkaline solution of the phenol, then dried and passed into a cold solution of the diazo compound The most important of these colours is para nitraniline red, which is dyed in enormous quantities on cotton pieces The pieces are first prepared by running them on a padding machine through a solution made up of 30 grms β naphthol, 20 grms caustic soda, 50 grms turkey-red oil, and 5 grms tartar emetic in 1,000 grms (1 litre) water They are then dried on the drying machine, and are passed, after being allowed to cool, into the diazo solution, which is prepared as follows 15 grms para nitraniline are dissolved in 53 c.c hydrochloric acid (34°Tw) and a sufficiency of water To the cold mixture a solution of 10.1 grms sodium nitrite is added while stirring The whole is then made up to 1,200 c.c and just before use 60 grms sodium acetate are added The colour is developed almost immediately, but it is well to allow the cotton to remain in contact with the solution for a few minutes The dyed cotton is squeezed, washed, soaped slightly, and finally rinsed in water and dried A brilliant red is then obtained which is fast to soap but not to light If the para-nitraniline used in the foregoing process is replaced by meta-nitraniline, a yellowish orange colour is obtained, with a naphthylamine, a claret red, with amido-azo-toluene, a brownish red, with benzidine, a dark chocolate, with dianisidine, a dark blue, and so on The dyed colours are fast to washing and are much used in practice, particularly the para-

FIG 2—CLOSED BEAM DYEING MACHINE IN WHICH THE DYE SOLUTION IS DRAWN THROUGH THE CORE AND BEAM IN THE DIRECTION INDICATED BY THE ARROWS

nitraniline red, which has served as a substitute for turkey red, although it is not so fast to light as the latter Superior results can be obtained by substituting Naphthol AS (the unilide of -oxynaphthoic acid) and other related products for β naphthol The combinations of these compounds with various diazotized amines result in shades which sometimes differ from those with β naphthol, generally giving improved appearance and almost always colours of superior fastness Some will stand the full bleaching process A further advantage is that the cotton shows decided direct affinity for Naphthol AS products and there is no necessity to dry the material after padding E Higgins (1927) has given valuable information regarding the behaviour of insoluble azo colours

(3) Mineral colours These include chrome yellow, iron buff,

prussian blue, manganese brown and khaki.

Chrome yellow is only useful in cotton dyeing as a self colour, or for conversion into chrome orange, or, formerly in conjunction with indigo, for the production of fast green colours. The cotton is first impregnated with a solution of lead acetate or nitrate, squeezed, and then passed through a solution of sodium sulphate or lime water to fix the lead on the fibre as sulphate or oxide

FIG. 3.—DYEING BY THE SPINDLE SYSTEM (IMPROVED FORM) IN WHICH THE CONTAINER FOR THE FRAME HOLDS THE COPS ON PERFORATED SPINDLES. IN THIS VESSEL THE CONTAINER WITH ITS CHARGE OF COPS IS CONNECTED WITH THE CIRCULATING SYSTEM FOR DYE LIQUOR.

of lead. The material is then passed through a solution of bichromate of potash. The colour is changed to a rich orange by a short, rapid passage through boiling milk of lime, and at once washing with water, a basic chromate of lead being thus produced. The colour is fast to light, but has the defect of being blackened by sulphuretted hydrogen.

Iron buff is produced by impregnating the cotton with a solution of ferrous sulphate, squeezing, passing into sodium hydrate or carbonate solution, and finally exposing to air, or passing through a dilute solution of bleaching powder. The colour obtained, which is virtually oxide of iron, or iron-rust, is fast to light and washing.

Prussian blue is applicable to wool, cotton and silk, but since the introduction of coal tar blues its employment has been very much restricted. The colour is obtained on cotton by first dyeing an iron buff, according to the method just described, and then passing the dyed cotton into an acidified solution of potassium ferricyanide, when the blue is at once developed. A similar method is employed for silk. Wool is dyed by heating it in a solution containing potassium ferricyanide and sulphuric acid. The colour is developed gradually as the temperature rises. It may be rendered brighter by the addition of stannous chloride. On wool and silk prussian blue is very fast to light, but alkalis turn it brown (ferrie oxide).

Manganese brown or bronze can be applied in wool, silk and cotton dyeing. The animal fibres are readily dyed by boiling with a solution of potassium permanganate, which, being at first absorbed by the fibre, is readily reduced to insoluble brown manganic hydrate. Since caustic potash is generated from the permanganate bath in order to counteract this effect. Imitation furs are dyed in this manner on wool plush, the tips or other parts of the fibres being bleached by the application of sulphurous acid. Cotton is dyed by first impregnating it with a solution of manganous

chloride, then dyeing and passing into a hot solution of caustic soda. There is thus precipitated on the fibre manganous hydrate, which by a short passage into a cold dilute solution of bleaching powder is oxidized and converted into the brown manganic hydrate. This manganic bronze or brown colour is very susceptible to, and readily bleached by, reducing agents, hence when exposed to the action of an atmosphere in which gas is freely burnt, the colour is liable to be discharged, especially where the fabric is most exposed. In other respects manganic bronze is a very fast colour.

Khaki is a mixture of iron buff and chromium oxide. The green shades of khaki are as a rule most sought after and on this account it is necessary to secure the deposition of much chromium on the fibre. This may be done by tanning and then destroying the tannic acid with sodium bichromate, otherwise this would destroy the cotton.

Dyeing on a Large Scale.—Textile fibres may be dyed in all forms in which they appear during the course of manufacture from loose fibres to fabrics. Dyestuffs are usually applied in solution or decoction with water and this is frequently heated, while the material is immersed in it. During the process the material to be dyed or the dye liquor or both must be almost continuously moved about in order to effect uniform or even dyeing. Numerous machines are used to effect this movement for particular kinds of material and also to secure uniform heating of the vessel, devices are fitted for preventing the material from coming into contact with the steam pipes. Loose material is liable to become matted together so machines have been arranged with hooks or fingers to prevent this. It is best dealt with by circulating the liquor through the material (fig. 1). Loose dyed wool is especially useful in producing fancy fabrics with fibres dyed in different colours.

Yarn Dyeing.—Yarn is dyed in the form of hanks, warps, cops and cheeses. The hank form involves the most simple devices for obtaining even results by turning the material. Machines made to imitate the effect of turning the yarn by hand over wooden pegs, take the form of a series of reels each holding about 2 lb. of yarn which are arranged so that large batches can be lifted in and out of the liquid automatically. In other machines the yarn is arranged on rods or carners which revolve on a central axis into half cylindrical dye vats and, during the revolution, the rods are turned so that the yarn moves to another position. Machines have been introduced for dyeing warps on the beam, the dye liquor being

FIG. 4.—DYE JIGS THROUGH WHICH THE CLOTH IS PASSED IN SUCCESSION OR THE JIGS CAN BE USED SEPARATELY AFTER THE CLOTH ON THE BATCH HAS BEEN PASSED BY DRIVING ROLLERS THROUGH THE DYE LIQUOR OVER THE GUIDE ROLLERS, AND THE SQUEEZING ROLLER APPLIED

caused to circulate through the material, and the system meets with considerable success.

Large quantities of yarn, especially cotton, are dyed in the cop, for wett. The main advantage of this method is at once apparent, inasmuch as the labour, time and waste of material incurred by reeling into hanks and then winding back into compact form, so as to fit into the shuttle are avoided. A thin tapering perforated metallic tube is inserted in the hollow of each cop. The cops are then attached to a perforated disc (which constitutes the lid of a chamber or box) by inserting the protruding ends of the tubes into the perforations. The chamber is now immersed in the dye bath

and the hot liquor is drawn through the cops by means of a centrifugal pump and returned continuously to the dye bath. This principle is known as the skewer or spindle system.

In the so called "compact" system of cop dyeing the cops are packed as closely as possible in a box, the top and bottom (or the two opposite sides) of which are perforated, the interstices between the cops being filled up with loose cotton, ground cork or

FIG. 5.—THE WINCH WHICH DRAWS THE PIECES IN ROPE FORM INTO THE VAT CONTAINING DYE LIQUOR OVER A GUIDE ROLLER BETWEEN PEGS. Without pegs the cloth can be treated at open width, protected from the heating coil by the perforated wall.

sand. The dye liquor is then drawn by suction or forced by pressure through the box, thus permeating and dyeing the cops.

Dyeing of Pieces.—Plain shades are usually dyed in the piece, this being the most economical and at the same time the most expeditious means of obtaining the desired effect. In the dye jigger (fig. 4) the goods are passed backwards and forwards over guide rollers between two batching rollers. The arrangement admits of treating a large quantity of material with comparatively little dye liquor. Another machine is that shown in fig. 5. This is suitable for heavy fabrics. The pieces are stitched end to end in a band which passes over a winch. Washing off may be done on the same machine.

Except for the dyeing of light shades only the preliminary operations of bleaching (washing and scouring) are carried out before dyeing.

Theory of Dyeing.—The peculiar property characteristic of dye stuffs, as distinguished from mere colouring matters, namely, that of being readily attracted by the textile fibres, notably the animal fibres, appears to be due to their more or less marked acid or basic character. Intimately connected with this is the fact that these fibres also exhibit partly basic and partly acid characters due to the presence of carboxyl and amido groups. The behaviour of magenta is typical of the basic colours. Rosaniline, the base of magenta, is colourless, and only becomes coloured by its union with an acid, and yet wool and silk can be as readily dyed with the colourless rosaniline (base) as with the magenta (salt). The explanation is that the base rosaniline has united with the fibre, which here plays the part of an acid, to form a coloured salt. It has also been proved that in dyeing the animal fibres with magenta (rosaniline hydrochloride), the fibre unites with rosaniline only, and liberates the hydrochloric acid. Further, magenta will not dye cotton unless the fibre is previously prepared, e.g., with the mordant tannic acid, with which the base rosaniline unites to form an insoluble salt. In dyeing wool it is the fibre itself which acts as the mordant. In the case of the acid colours the explanation is similar. In many of these the free colour-acid has quite a different colour from that of the alkali salt, and yet, on dyeing wool or silk with the free colour-acid, the fibre exhibits the colour of the alkali-salt and not of the colour acid. In this case the fibre evidently plays the part of a base. Another fact in favour of the view that the union between fibre and colouring matter is of a chemical nature, is that by altering the chemical constitution of the fibre its dyeing properties are also altered, oxycellulose, nitrocellulose and

acetate silk, for example, have a greater attraction for basic colours than cellulose. Such facts and considerations as these have helped to establish the view that in the case of dyeing animal fibres with many colouring matters the operation is a chemical process, and not merely a mechanical absorption of the dyestuff. A similar explanation does not suffice, however, in the case of dyeing cotton with the direct colours. These are attracted by cotton from their solutions as alkali salts, apparently without decomposition, the affinity existing between the fibre and colouring matter is distinctly feeble in comparison with wool. This fibre is capable of taking up as much as 20% of acid colour without appearing bronzed. Cotton absorbs under favourable conditions about 2% of actual direct colour.

The dyeing of cotton is most probably of a physical character but there are different opinions as to the nature of this. Some favour colloidal, some purely mechanical (solid solution) and some electrical theories. The latter explains phenomena which occur during dyeing and in some instances supports the chemical as well as the mechanical theory. In the case of colours which are dyed on mordants the question is merely transferred to the nature of the attraction which exists between the fibre and the mordant. G. T. Morgan finds that the co-ordination theory of valency explains and correlates known facts with regard to mordant dyeing.

The trend of advance in the industry in America, in Great Britain and on the Continent is shown by a real endeavour to meet the demands for fast dyeings and a greater value and utilization of scientific methods in the investigation of processes and the effects produced by them. Colour measuring and matching instruments have been greatly improved and may prove of value in giving a more definite expression to fastness. Products produced by the action of light on vat colours have been isolated, the first of these being the oxidation product, isatin, from indigo dyed cotton (1927). In Great Britain the Society of Dyers and Colourists has appointed a committee with F. Scholefield as chairman to consider the whole question of fastness and already contributions have been made towards elucidating some of the problems. Many of these can only be solved by steady co-operation of workers. In December 1925 the dyeing industry suffered a severe loss by the death of Edmund Knecht, who had enriched technical and analytical chemistry by important researches, many of which are recorded in the pages of the *Journal of the Society of Dyers and Colourists* "A Manual of Dyeing" by E. Knecht, C. Rawson and R. Loewenthal is a work of reference of international fame. (E. H.)

DYER, SIR EDWARD (d. 1607), English courtier and poet, son of Sir Thomas Dyer, Kt., was born at Sharpham Park, Somersetshire. He was educated, according to Anthony a Wood, either at Balliol college or at Broadgates hall, Oxford. He left the university without taking a degree, and after some time spent abroad appeared at Queen Elizabeth's Court. His first patron was the earl of Leicester, and he is mentioned by Gabriel Harvey with Sidney as one of the ornaments of the Court. Sidney in his will desired that his books should be divided between Fulke Greville (Lord Brooke) and Dyer. He was employed by Elizabeth on a mission (1584) to the Low Countries, and in 1589 was sent to Denmark. He was knighted and made chancellor of the order of the Garter in 1596. Wood says that many esteemed him to be a Rosicrucian, and that he was a firm believer in alchemy. He had a great reputation as a poet among his contemporaries, but very little of his work has survived. Puttenham in the *Arte of English Poetrie* speaks of "Master Edward Dyer, for Elegie most sweete, solemne, and of high conceit." One of the poems universally accepted as his is "My Mynde to me a kingdom is."

See the collection of his works by A. B. Grosart, *Fuller Worthens Library* (vol. IV, 1876).

DYER, JOHN (c. 1700–1758), British poet, the son of a solicitor, was born in 1699 or 1700 at Aberglasney, in Carmarthenshire, and died at Coningsby on Dec. 15, 1758. In 1726 his first poem, *Grongar Hill*, appeared in a miscellany published by Richard Savage, the poet. It was an irregular ode in the so called Pindaric style, but Dyer entirely rewrote it and printed it separately in 1727. *Grongar Hill*, as it now stands, is a short poem

of only 150 lines, describing in language of much freshness and picturesque charm the view from a hill overlooking the poet's native vale of Towy. A visit to Italy bore fruit in *The Ruins of Rome* (1740), a descriptive piece in about 600 lines of Miltonic blank verse. He was ordained priest in 1741, and held successively various Lincolnshire parishes. In 1757 he published his longest work, the didactic blank verse epic of *The Fleece*, in four books, discussing of the tending of sheep, of the shearing and preparation of the wool, of weaving and of trade in woollen manufactures.

His poems were collected by Robert Dodsley and by Edward Thomas in 1903, for *The Welsh Library* vol. 11.

DYER, REGINALD EDWARD HARRY (1864-1927), British general, born at Murree in the Punjab, Oct. 9, 1864, and educated at Middleton College, Co. Cork, entered the army in 1885 and took part in 1886-87 in the Burma campaign, in 1888 in the Hazara expedition in 1895 in the relief of Chitral, in 1901-02 in the Wazirist in blockade and in 1908 in the operations in the Zikri Khel country. In World War I he commanded the 15th infantry brigade. He was awarded the C.B. in 1916 for his success against the Stribd raiders while in charge of the Eastern Persian Gordon and published in account of his experiences *The Raiders of the Sarhad* (1921). In April 1919 while Dyer was brigade commander at Jullundur, he was called to quell a rising at Amritsar. He used military force, opening fire, without warning on an unarmed crowd and causing more than 300 deaths and 1,000 other casualties. The Amritsar incident roused much hostile feeling in India, and the Indian national council bought the Jullundur Bagh, the site of the massacre, as a "martyr's memorial" to be used as a place of pilgrimage.

General Dyer died on July 23, 1927, at Long Ashton, Bristol. See I. Colvin, *Life of General Dyer* (1929).

DYERSBURG, a city of northwestern Tennessee, U.S., 15 mi. from the Mississippi river, the county seat of Dyer county. It is on federal highway 51, and is served by the Gulf, Mobile and Ohio and the Illinois Central railways. The population was 10,865 in 1950 and 10,234 in 1940 by the federal census. Dyersburg, originally Melver's Bluff, was founded about 1856.

DYES, NATURAL The utilization of plant products for dyeing is of ancient origin, and without doubt at the first consisted in the staining of material with the coloured juices of fruits, flowers and the like. It would be observed that certain of these effects resisted the washing process, a true fixation of the colour having occurred, and such discoveries would in course of time be extended, but on the other hand few substantive dyestuffs exist in nature the variety of shade they yield is limited and their effects in the main are not permanent in sun light. Again the observation that the leaf juice of the indigo plant develops a blue colour on keeping and that the sea snail *Murex*, when crushed and exposed to light acquires a purple tint would prepare the way for the subsequent application to fabrics of both the indigo and the purple of the ancients. The process of isolating indigo from the plant was no doubt preceded by a practice of developing this colouring matter in the leaf itself and the employment of the latter as such in the dyeing process, a method which is still adopted in remote parts of China and Africa.

The antiquity of the use of indigo is evident from the discovery at Thebes of a garment dyed therewith, dating from about 3000 B.C., while the words "blue" and "purple" occurring in Exodus, xxv, 4, and xxxv, 25, can hardly refer to colours other than indigo and the Murex purple. The latter, also known as "Tyrian" or "royal" purple was of much importance, and the famous Tyre, where, according to legend, it was discovered, became famous for its production. The scriptural quotation "clothed in purple and fine linen" refers not only to this dyestuff but also to its expensive character. It was only as the result of the discovery of the art of mordanting however, which occurred (probably in India) not later than 1000 B.C., that the practice of dyeing really advanced for as a result many natural colouring matters otherwise useless could be applied to fabrics. Thus the Biblical scarlet without doubt refers to the colour given by kermes on alum mordanted material whereas both madder and the

lac dye of India, which have been in use from time immemorial for red dyeing, give this colour only to fabrics which have been similarly treated. Very ancient too is the use of "archil," a colour resulting from the action of ammonia on stale urine or certain lichens and referred to by Pliny as of service in reinforcing the shade of the Tyrian purple. Early references to mordant yellow dyestuffs are meagre, though according to the same author, "cotinus" (evidently the shrub *Rhus cotinus*, that is, young fustic and weld, which was the more valuable of the two) was in use for this purpose. Again, saffron was known to both Egyptians and Greeks, and there is evidence of Egyptian use of the yellow colouring matter of safflower as a dye or stain for mummy cloths.

As a result of the discovery of Mexico and South America by the Spaniards at the end of the 15th century, many important dyes indigenous to those countries, as for instance, logwood dyestuff and the like, became available in Europe and provided the dyer with a range of effects formerly inaccessible. Kermes was soon replaced by the richer cochineal, and the employment of weld, young fustic and certain of the minor natural dyestuffs greatly decreased or was restricted to the production of special effects. (A.G.P.)

DYES, SYNTHETIC Synthetic or coal tar, dyestuffs known also as aniline dyes, are like the dyestuffs of natural origin (i.e., fustic, logwood, cochineal, saffron, etc.) in that they are complex compounds of carbon hydrogen and oxygen. By far the greater number also contain nitrogen and sulphur, the metallic elements chromium, copper and zinc are present in a few. Invariably too, they are derived from compounds belonging to the aromatic class of organic chemical compounds (see CHEMISTRY Organic Chemistry), e.g., benzene, toluene, the three xylenes, naphthalene, acenaphthene, anthracene and carbazole.

Coal tar, or oil, dyestuffs do not exist as such in coal tar but are made from these nine primary substances, which do occur as such in coal tar or which are formed along with the tar in the coking of coal. The first three are water white liquids at ordinary temperatures, the last four are white solids. All are characterized chemically by the presence of the well known benzene ring, and the last six may be regarded as simple or complex derivatives of benzene in which hydrogen atoms have been replaced by radical consisting primarily of carbon and hydrogen.

Only one of the substances is commonly known to the layman. Ordinary moth balls are pure naphthalene.

Raw Materials—In the destructive distillation of coal for the production of coke or gas, many organic chemical reactions take place with the formation of a wide variety of organic chemical compounds. The nine basic raw materials are among these compounds, they do not exist as such in coal. The products distilling from the coke or gas retorts are fractionally condensed, that is, to say, the more complex compounds with the higher boiling points are liquefied first from the gas stream, then the middle cuts consisting of compounds with intermediate boiling points, are condensed and finally the lighter oils with the lowest boiling point are obtained. The uncondensed gases passing through the condensing system, composed for the most part of carbon monoxide, hydrogen and methane, are either fed into gas mains or used as fuel for the coke ovens.

The first fraction condensed is coal tar. It contains little or no benzene, toluene or xylene these latter materials comprising the bulk of the lighter oils. But it does contain the anthracene, carbazole and acenaphthene and a part of the naphthalene formed in the coking process. For the separation of its valuable constituents, the coal tar is fractionally distilled in great retorts holding 20-30 tons. Among the products taken off from the lower fractions are naphthalene and acenaphthene, whereas, from the highest fractions, anthracene and carbazole are obtained. The residue left in the retorts is pitch, used either for the manufacture of roofing materials or in road construction.

In the United States, coal tar distillers as a rule do not carry the distillation as far as it is taken in Europe. The anthracene and carbazole fractions are left in the pitch. The latter then is softer and more pliable, and therefore more useful in road construction. The anthracene derivatives required for dyestuff manufacture are made synthetically from phthalic anhydride, which in turn is made from naphthalene. Carbazole requirements in the United States are comparatively low and are met either by taking the anthracene and carbazole fractions from a very small portion of the tar distilled, or by making the material synthetically from nitro- or aminodiphenyl. Because of the economics involved and of the relative unimportance of synthetic dyes derived from acenaphthene, this material is not separated from coal-tar fractions in the United States for use in the dyestuff industry.

Naphthalene and acenaphthene are present also in the middle cuts from the coke retorts. These cuts are likewise fractionally distilled for the separation of their valuable constituents. Finally, the lighter oils are fractionated for the separation of benzene, toluene and a mixture of the xylenes.

It must not be inferred that the nine basic raw materials of the dyestuff industry are the only valuable products obtained from coal tar fractions, or that distillation is the only process used for their separation and purification. Various cuts are washed with alkali for the removal of acids such as phenol and the cresols, and with acids for the removal of bases such as pyridine, picoline and quinoline. From such washings, the products named are recovered.

The nine raw materials obtained in a crude state by the processes outlined are refined for usage in the organic chemical industry (1) by fractional distillation, (2) by hot pressing, (3) by washing or crystallization and (4) by sublimation. Hot pressing consists of applying pressure to a mixture of solids and oils at an elevated temperature, the lower-boiling oils being thus squeezed out. This process is applied particularly to naphthalene. Washing consists of thoroughly mixing the material to be purified with a solvent, whereby undesired compounds are dissolved. The mixture is then filtered either at ordinary or at elevated temperatures. This process is applied primarily in the purification of anthracene.

Intermediates—From the nine basic raw materials, properly refined, literally thousands of products, termed intermediates in the dyestuff industry, can be manufactured. In their production, many products of the heavy chemical industry, such as sulphuric, nitric and hydrochloric acids, caustic soda and caustic potash, sodium carbonate, ammonia and chlorine, must also be used. Consequently, these products, too, might be considered raw materials in the dyestuff industry.

For the manufacture of by far the greater number of these intermediates, a few relatively simple chemical reactions, termed by the dyestuff chemist "basic intermediate processes," are used. Any process of this type consists in the application of a chemical reaction of a particular type to any one of a number of different materials. For example, benzene, toluene, xylene and naphthalene are nitrated, *i.e.*, subjected to the action of nitric acid. Nitration then is a "basic intermediate process," and, in the case of the dyestuff industry, the most common one.

Other widely used processes include reduction, sulphonation, chlorination, oxidation, hydrolysis by fusion with caustic soda or potash, alkylation and amidation.

A few examples (I-VII) will illustrate the enormous diversity of intermediates which can be made from the nine basic raw materials.

(I) Nitration, reduction and alkylation

(II) Sulphonation and fusion

(III) Chlorination, nitration and amidation

(IV) Sulphonation and amidation

(V) Alkylation, sulphonation and fusion

(VI) Oxidation, sulphonation, and chlorination

(VII) Sulphonation, nitration, reduction, and fusion

In commercial practice the intermediates shown in the given examples (I-VII) are not necessarily made in the designated manner, it is possible in many cases to make a given product over two or even three and four routes. Here chemical economics comes into play. Frequently, because of the phenomenon of isomerism (q.v.) valuable by-products are formed and what is an economical process for one manufacturer may be an uneconomical process for another. Indeed, it has happened in the dyestuff industry that uses have been found for a substance originally regarded as a by-product which have made this substance the most desired product of a reaction, the former main product being coming then the by-product. Sometimes too a new and improved route may be discovered by one manufacturer and patented.

A single example having to do with the manufacture of a very important dyestuff, sulphur black, will illustrate this choice of routes. The most important intermediate in general use for the manufacture of this dye is 2,4-dinitrophenol. It can be made from benzene in three ways:

Isomerism plays an extremely important role in the manufacture of dyestuffs and often determines the route over which an intermediate is made. The very important compound 1,5-diaminoanthraquinone for example, can be made either by dinitrating anthraquinone, separating the 1,5- and the 1,8 isomers and then reducing the 1,5-dinitro compound to the corresponding diamine, or by disulphonating anthraquinone, separating the 1,5- and the 1,8 isomers and then subjecting the 1,5-disulphonic acid to the action of aqueous ammonia at high temperatures and pressures. In the first case, the by-product 1,8-dinitroanthraquinone possesses little utility whereas in the second, the 1,8-disulphonic acid can be used much more advantageously.

Sometimes the purity of an intermediate when made over two routes determines the process used for the manufacture of the product. It is very difficult, for example, to obtain α -naphthol of high purity by sulphonating naphthalene and then fusing the sulphonic acid with caustic. On the other hand, a relatively pure material can readily be made by the hydrolysis of α -naphthylamine with acid. All this follows from the fact that it is much easier to obtain pure α -nitronaphthalene than it is to obtain pure naphthalene α -sulphonic acid.

Not only can basic intermediate processes be applied to the nine raw materials of the dyestuffs industry, but also to many products derived from these raw materials. For example, the nitrotoluenes may be chlorinated, or the naphthylamines, sulphonated. Here, too, isomeric products are formed and separated. Great difficulty is occasionally encountered in the separation of these highly substituted isomeric products because of the similarity of their chemical and physical properties.

From a consideration of the use of nine basic raw materials (seven of them of extreme importance), of the application of at least ten important basic intermediate processes and of the phenomenon of isomerism, it must be apparent that the number of possible intermediates that can be made will run into the thousands. Such is the case. On the other hand, it is estimated that 90% of the tonnage of synthetic dyestuffs made in the world is derived from less than 200 intermediates. A so-called "specialty dyestuff," sold in limited quantities for one particular usage, may require one or more intermediates of use for no other organic chemical product.

DYESTUFFS

Nomenclature—Any company of consequence manufacturing dyestuffs produces, as at least part of its line, exactly the same substances that are made by competitive firms. There is no difference chemically between the dyestuff called eosine when made in Italy, England, Germany or the United States. The same may be said for a wide variety of dyes, each of which has become, following its discovery and introduction, a standard article of commerce. Both process and product patents expire after a given number of years, and any manufacturer is then free to produce a dyestuff on which another firm previously held a monopoly.

The nomenclature employed in the dyestuffs industry follows

from these facts. When the chemical compound benzene meta diazo bis-metaphenylenediamine dihydrochloride was discovered in 1863 and manufactured as a dyestuff, it was sold under the simple name of Bismarck brown. Its success was instantaneous. In time it was manufactured by no less than 21 firms, and in almost all cases under the name originally given it, Bismarck brown. When the chemical compound tetraethyldiamino orthocarboxy phenyl xanthyli chloride was first manufactured in 1887, it was sold under the name rhodamine B. In time, 12 other manufacturers made the product and 11 of them sold it under the name of rhodamine B. When a closely related chemical compound, diethyldiamino orthocarboxy phenyl xanthyli chloride was first made in 1892 and found to dye textile fabrics in much yellower shades of red than rhodamine B, it was marketed under the name of rhodamine 6G. In time 11 manufacturers made the product, and 7 of them sold it under the name of rhodamine 6G.

In general, it may be said that synthetic dyestuffs are so complicated structurally that it would be impossible to market them under their chemical names. It is for this reason that names such as eosine, Bismarck brown and rhodamine are invented. Some times such names are trade marked by the original manufacturers, and, since trade marks as a rule run much longer than patents, it is necessary on occasions for other producers to invent new names for a particular dyestuff or line of dyestuffs.

A perfect example of this is found in the marketing of vat colouring matters derived from anthracene. The first one of these was discovered in 1901 and shortly thereafter was sold as indan threne blue R by the Badische company in Germany. Soon others of these anthraquinone vat dyestuffs were discovered and manufactured. All were sold under the trade marked name of indan threne, e.g., indanthrene yellow G, indanthrene green G, indanthrene violet R, indanthrene golden orange G, etc. By the time World War I ended, original patents having expired, these colours were being made in Switzerland, England and the United States. But they could not be marketed under the name indan threne. In Switzerland, the Society of Chemical Industry, Basel, called them cyanone, in Great Britain, Scottish Dyes called them caledon, in the U.S., the Calco company, calcosol, the du Pont company, ponsol, and in Japan, a few years later, the Japanese Dyestuffs Manufacturing company, vijayanthrene. Thus, caledon yellow G is chemically identical with indanthrene yellow G, calcosol yellow G and vijayanthrene yellow G, etc.

Usually, the trade-names given to dyestuffs designate all characteristics of the products that can be gathered into a single catchy word. Thus, the name Indanthrene is derived by combining *ind* of indigo, designating a vat colouring matter, and *anthrene* from anthracene—the whole name thus implying a vat dyestuff from anthracene. But occasionally names that have little or nothing to do with dyestuff characteristics are chosen. In these cases, however, the names are suggestive: *sirius* yellow G, *orion* blue 2B, *nigrosine* B, *pluto* black BL, *malachite* green, etc.

Early in their development of the industry, the Germans invented a system of nomenclature whereby the approximate shade of a dyestuff could be designated, letters being added to its name to indicate variations in shade. Most common of these letters were G for *grün* (green), B for *blau* (blue) and R for *rot* (red). If the product gave a green shade of blue on dyeing, it was designated as blue G, and, as it gave progressively greener dyeings, as blue 2G, blue 4G or even blue 6G, the latter being a very greenish blue. If, on the other hand, the shade of the blue dyeings tended to purple, the letter R was suffixed, blue R, blue 2R and blue 3R, etc. The system proved to be helpful to the industry and has been generally adopted.

Theoretical.—Intermediates used in the manufacture of dyes derived from benzene, toluene, the xylenes, naphthalene, acenaphthene and carbazole are in general white or colourless substances. Intermediates from anthracene are coloured, and here in a few cases a product may be both an intermediate and a dyestuff. The compound 1,4-diaminoanthraquinone, for example, is an excellent product for colouring gasoline in violet shades, a usable material for dyeing acetate silk in bluish red shades and at the same time an intermediate for several extremely

important anthraquinone vat dyestuffs. Thus, with the introduction of synthetic fibres into world commerce, and with the wide employment of colouring matters in the modern world, the line of demarcation between an intermediate and a dyestuff cannot be so sharply drawn as it was prior to World War I.

Early in the development of the industry it was found that many synthetic dyestuffs known at the time, when treated with a reducing agent (e.g., with hydrogen) lost their colour. The resulting colourless bodies, known as leuco dyes or leuco bases, contained a larger percentage of hydrogen than the dyestuffs and could be converted into the latter by reversal of the process, i.e., by oxidation. In the years from 1865 to 1910 much work was done by dyestuff chemists, particularly in Germany and Switzerland, to clear up the problem of why one compound is coloured, whereas a very near relative is colourless. O. N. Witt, A. Hantzsch and R. Nietzki being the leaders in this work.

As early as 1866 Witt propounded a theory of colour which not only has withstood all criticism levelled against it, but has been strengthened with the discovery in subsequent years of many new classes of compounds useful for dyeing. Witt assumed that colour is dependent upon the presence of groups of atoms, held together by valence bonds in certain specified ways, in the organic chemical molecule. He termed the colour-giving group the chromophore, and the compound containing it the chromogen. The chromogens of themselves are not dyestuffs, Witt argued these only being formed by the introduction into the molecule of one or more additional groups of atoms which are capable of salt forming properties, and which may be either basic or acidic. In time, certain of these groups came to be known as auxochromes, the most common ones being NH_2 , $\text{N}(\text{CH}_3)_2$ and OH.

One of the simplest examples to illustrate Witt's theory is found in the relationship existing between benzene, hydroquinone and benzoquinone.

The first two of these substances are assigned so called Kekulé structures with alternating double and single bonds in the ring, whereas benzoquinone is assigned the paraquinoid structure in order that the valencies of the carbon atoms to which the oxygen atoms are attached may be satisfied. Thus, by the shifting of bonds, colour is produced. The paraquinoid structure is therefore the chromophore, and all compounds containing this grouping should be coloured, according to Witt's assumption. Such is generally the case, although a few exceptions have been noted. Some further similar examples are given below.

In the given examples, the indophenol which is blue in colour is not a dyestuff, whereas magenta, red in colour, is a dyestuff. This seeming contradiction follows from the fact that many

coloured compounds are not useful as dyestuffs since they may not have affinity for fibres of various sorts or since they may have poor fastness properties when dissolved in an organic solvent to colour it. The indophenol cited has little or no affinity for natural or synthetic fibres. On the other hand, it could be used to colour glycerine but the colour would be entirely too fugitive for commercial use.

The effect of auxochromes in modifying the colour of a compound with the paraquinoid chromophore can be illustrated by the example of anthraquinone and such of its derivatives as are listed below.

Although the paraquinoid chromophore is the most common one in the dyestuff industry, several other important types are also recognized. One of these is the indigo, which occurs in nature and in a large number of further cases of closely related structure. The orthoquinoid chromophore, characteristic of *o*-benzoquinone is similar to the indigo but is much less important since it occurs in only a few dyestuffs of commercial importance. Moreover some compounds of the diphenyl series containing the grouping $O=C-C=$ are characteristic of both the indigos and orthoquinoids are also coloured, the relationship being shown in the following example:

It will be noted that when the $O-C(=O)-$ grouping is changed into $HO-C(=O)-$ the product is no longer coloured.

Only one other grouping is of extreme importance in the dyestuff industry. It is responsible for colour in a large series of compounds made by the diazotization and it can be expressed as $R-N=N-R$ where R stand for substituted hydrocarbon radicals of the benzene, toluene and *n*-phthalene series the most common substituent groups being NH_2 , OH , SO_3H and $COOH$. An example of a widely used dyestuff made from sulphamic acid and beta-naphthol will illustrate the chromophore.

In the given example, the function of auxochromic groups is illustrated in two directions. First, diazo compounds will not react with hydrocarbons of the benzene series themselves to yield dyestuffs, substituent groups such as $-NH_2$ and $-OH$ must be present if dyestuffs are to be produced. Second, the group SO_3H is not necessarily an auxochromic group. In orange II it merely imparts water solubility to the product. If aniline is substituted for sulphamic acid, an oil soluble dyestuff, made and sold as such, results. (See also Compound 6, below.)

It was not until the fourth decade of the 20th century that coal-tar derivatives based on the chromophore present in the natural colouring matters of the chlorophyll and haem classes were manufactured and sold commercially as dyestuffs and pigments. All of them belong to the phthalocyanine class and contain the porphyrine chromophore, porphyrin being the parent structure present in the above mentioned natural products. The most important dyestuff of the group is copper phthalocyanine. The relationship is shown in the following structures:

Witt's theory of colour has been more fully explained in the 20th century by applying to it other and newer theories of organic chemistry, particularly those having to do with ionization and with the role of the electron in valency. Although a complete description of these newer theories would be outside the scope of this article, a brief discussion of the manner in which they regard the paraquinoid chromophore may be given here.

As may be seen from a consideration of the examples mentioned above, paraquinoid compounds result in general from the oxidation of substances with structures of a certain type. As has been noted, these latter substances are termed leuco compounds or leuco bases in the dyestuff industry, and up until the decade 1900-10, they and their oxidation products (the dyestuffs) were considered to be made up of molecules to which unique structure could be assigned. But in the first decade of the 20th century Hantzsch introduced the concept of tautomerism into the theory; thus, he explained the change of colour that takes place upon the conversion of pyranthiophenol into its sodium salt by assuming that two forms of the phenol exist in equilibrium with each other, the one nonquinoid, colourless and a very weak acid, the other one quinoid, red in colour and a very strong acid. Upon the addition of alkali, Hantzsch argued, salts of the strong acid are formed almost exclusively, such quinoid salts he assumed to be red.

On reversal of the process by the addition of acids the equilibrium again shifts back and the colourless nonquinoid form of the free naphthiophenol predominates.

(The "classical" structures given here in which each nitrogen atom forms five covalent bonds, are the ones employed by Hantzsch. Although newer theories hold that the maximum covalency of nitrogen is four [see Valence] the replacement of these structures by their modern counterparts would in no way affect the present discussion.)

A rather different theory, which, however, likewise admitted the possibility of variable structure, was advanced in 1907 by A. Bayer, who suggested that the colour of a dye-stuff such as malachite green is caused by the oscillation of an anion from one end of the molecule to the other. The type of oscillation thus proposed for malachite green is illustrated by the equation

(in which again the "classical" structures, a nitrogen atom forming five covalent bonds, are employed). It will be noted that each of these two structures contain one quinoid ring.

The theories of Hantzsch and of Baeyer suffered from the fact that, at the time at which they were proposed, the distinction between covalent and electrovalent bonds was not fully realized. Somewhat later, however, in 1914, E. Q. Adams and L. Rosenstein advanced the theory that, since the observed colours of substances of the present type might be properties of their ions and not of any postulated un-ionized molecules, the transitions among the structures in question involve only redistributions of valence bonds and of electric charges, and do not require the movement of any atoms or ions. Thus, with the sodium salt of pyranthiophenol, the two structures proposed by Hantzsch might be replaced by the two corresponding ones

(which are given here in modern rather than classical form). If the theory of Adams and Rosenstein is correct there is no necessity to postulate, with Hantzsch, the existence of an un-ionized red quinoid form. Similarly, with malachite green, the two structures proposed by Baeyer might be replaced by

In these two cases, the sodium and chloride ions are considered to have nothing directly to do with the production of colour. Adams and Rosenstein, moreover, suggested that the colours of ions like the ones under discussion are caused by rapid oscillations of the ionic charges back and forth between the extreme positions characteristic of the various structures. In this way, they were able to avoid the necessity of assuming, with Baeyer, that a relatively heavy, and hence relatively immobile, anion is able to vibrate with

the extremely high frequency necessary to account for the absorption of visible light.

Further contributions to the theory of colour were made by J. Stieglitz (1924), who employed more or less the same approach as Adams and Rosenstein. The modern period may be said, however, to have started in the 1930s with the development of the theory of resonance. According to this theory the actual distribution of electric charge in any molecule or ion is always intermediate among the distributions characteristic of any given structure that may be written and of all the further structures that can be derived from the first by merely a redistribution of valence bonds and electric charges. Thus, the actual distribution of charge in the anion of *p*-nitrophenol is considered to be some sort of average of the distributions not only in the two above structures but also in several further structures, such as

Similarly, the distribution of charge in the cation of malachite green is considered to be some sort of average of the distributions illustrated not only in the two above structures but also in several further structures, such as

It is a corollary of the theory, which cannot be discussed further here, that the so-called "resonance" among these various structures leads to increases in the wave lengths at which the absorption of light occurs. If these increases are sufficiently great, the absorption of light may come into the region of the visible spectrum so that the substances are coloured.

That some such phenomenon occurs in organic compounds, there can be no doubt. F. A. Kekulé, who postulated the ring structure for benzene, was forced to accept the concept of a shifting of valencies, even in this substance, although he did not comprehend the nature of the shifting. He saw that if no such shifting occurred, two orthodibromobenzenes should exist

However, only one form exists, at any rate, no second form has ever been isolated.

In this connection it is pertinent to note that diphenylene ethylene, an unsubstituted hydrocarbon of the benzene series, and 2, 4, 6, 8, 10, 12-tetradecehexacene, a straight chain compound of carbon and hydrogen, are coloured. The important point, therefore, in colour formation seems to be the presence of a "conjugated" carbon chain, i.e. a chain of alternating single and double bonds between the carbon atoms that constitute the skeleton of a compound. Such a skeleton, present in each of the compounds of carbon and hydrogen mentioned above, permits the phenomenon called resonance to such an extent that both substances absorb light in the visible ranges of the spectrum. Yet they are nonionic. Moreover, in some instances, a coloured neutral molecule gives rise to a less deeply coloured, or even colourless, ion. For example, the intense yellow colour of a solution of *p*-nitrodimethylaniline in aqueous alcohol is largely discharged by the addition of hydrochloric acid, thus, the *p*-nitrodimethylanilinium ion must be

colourless, or nearly so. The reader must therefore be careful not to conclude that resonance, and hence colour, are properties

of only ions, since actually resonance is considered always to occur both in ions and in the corresponding neutral molecules. Most commonly, however (and in particular, in all the foregoing examples), the data are in at least qualitative agreement with the supposition that the depth of the colour of a substance is increased by any structural change which permits a more effective resonance.

Although the presence of the chromophore and auxochrome groups in organic compounds used as dyestuffs increases the possibility of resonance and thus brings about selective absorption of light in the visible ranges of the spectrum, all colourless organic compounds, too, show this same selective absorption, but in the invisible ranges of the spectrum. In some cases such selective action is exceedingly strong and plainly apparent. Highly refined anthracene and chrysene for example pure white in colour, exhibit marked bluish fluorescence, which results from the selective absorption of ultra violet light.

Two terms in general use in dyestuff chemistry should be defined here. Any change in the structure of a compound which shifts its absorption of light to longer wave lengths (*i.e.*, toward the red end of the spectrum) is termed *hythochromic* whereas any change that shifts it in the opposite direction is termed *hypsochromic*. But care should be used in the application of the two terms, for there are cases in which the effects are perceptible only when a colouring matter is applied to a particular fibre under certain conditions. A change in the molecular structure of a compound may give a hypsochromic effect when a dyestuff is applied to wool and yet give no effect at all, or even an opposite effect, when it is applied to cotton or to a synthetic fibre. The terms, therefore, are exact only if reference is made to the absorption spectra of coloured compounds when determined under exactly similar conditions.

It has been noted that coloured compounds are not necessarily dyestuffs, and that a product which will dye one material satisfactorily may not dye another. The problem why various fibres absorb and hold certain coloured compounds designated as dyestuffs has never been satisfactorily solved. Both silk and wool contain basic and acidic groupings in their molecular structures and the presence of such groups doubtless accounts for the fact that these materials are more readily dyed than cellulose fibres which contain only weakly acidic groupings. The vast majority of dyestuffs, too, contain basic or acidic groups in their molecular structures, many contain both.

Numerous theories have been advanced to account for the mechanism of dyeing, and it is clear that the process must be (1) purely physical adsorption, (2) actual chemical union or (3) a combination of both. Theories advanced in the decade between 1935 and 1945 stressed hydrogen bonding, and were based on relationships existing in the linear distances between reactive groups in fibre and dyestuff molecules. When these distances are approximately equal, the theory assumes, hydrogen bonding can occur; when grossly unequal, combination is impossible. This "molecular-spring" conception of the dyeing mechanism agrees in many cases with observable facts, and explains why a given organic compound may be utterly useless as a dyestuff for cotton or wool and yet be a very valuable colouring matter for acetate silk or some other synthetic fibre. But much work remains to be done before the theory can be generally accepted.

The fastness of a dyestuff on any fibre is in general, directly proportional to the chemical stability of its molecule against destructive agents such as oxygen, light, heat and certain salt solutions, or combinations of these. Chemically, the azo compounds for example are relatively unstable as compared with the indigos and anthraquinones. The latter are therefore in general, the faster dyestuffs on textile fibres. Copper phthalocyanine is an extremely stable substance, withstanding heat up to 900° F. without decomposition and resisting the action of oxidizing agents that would destroy other organic compounds. It is, therefore, an extremely fast colouring matter.

Processes for Making Dyestuffs.—Just as in the case of intermediates there are but a relatively few simple organic chemical processes used to convert intermediates into dyestuffs. These

processes, which may be termed "basic dyestuff processes," are applicable to a wide variety of intermediates. For example, each product in the large series of closely related compounds termed indophenols can be subjected to the action of sodium sulphide and sulphur, and a correspondingly large series of products, known as sulphur dyestuffs, can be thereby obtained. The process is commonly known as thionation. Other processes generally in use are diazotization, condensation, oxidation, halogenation and esterification.

Of all these basic dyestuff processes, thionation is the only one that is not clearly understood by the dyestuff chemist, *i.e.*, the only one in which he does not know the exact nature of the products resulting from the application of the process. In this process, compounds composed of giant molecules, and incapable of being crystallized and thoroughly purified, are formed, in many cases mixed products are obtained. The process, which can be carried out with or without the use of a solvent, is applicable not only to indophenols but also to a wide variety of intermediates, and to another series of compounds termed azines (See *Sulphur Dyes* below).

Diazotization consists in the treatment of an amine with nitrous acid, the latter generally being obtained, and the process being carried out, by the treatment of sodium nitrite with hydrochloric or sulphuric acid in the presence of the amine which has been dissolved or dispersed in cold water. The resulting diazonium salts are relatively unstable (hence, the use of cold water) and extremely reactive. Some are relatively insoluble at temperatures at which the process is carried out, whereas others are very soluble. In some cases, one amino group per molecule is so transformed, in other cases, two, in the latter event, the process is called tetrazotization. The following examples will illustrate the reaction. Two possible structures of the diazo and tetraazo compounds are shown, the latter one in each instance being analogous to the structure assigned to the dyestuffs that result from the subsequent condensation reaction (see below).

The dyestuff chemist generally writes the structures of the diazonium compounds as $\text{R}-\text{N}=\text{N}-\text{Cl}$, for, as will be shown later, the structures of the azo dyestuffs made from these intermediates are doubtless $\text{R}-\text{N}=\text{N}-\text{R}'$, where R and R' are residues of the benzene, toluene, xylene or naphthalene series containing one or more auxochrome groups. The alternative structure $\text{R}-\text{N}=\text{N}^+-\text{Cl}^-$ is however, generally considered to be the more correct and it is the one universally employed in the scientific literature.

Condensation is the most widely diversified of the dye making processes, for many types of compounds will condense with other compounds or even with themselves.

In some cases condensation occurs readily, in fact, when two intermediates are stirred together in cold water, in others condensation requires drastic conditions of reaction, particularly of temperature. Frequently, condensing agents such as dehydrating materials and "acid acceptors" (*i.e.*, weak bases like sodium

methane $H-C\equiv(C_6H_5)_3$. By the condensation for example of one mole of benzaldehyde with two moles of dimethylaniline the colourless compound tetramethyldiaminotriphenylmethane is formed. When this product is oxidized in acid solution to the corresponding carbinol, a loss of water occurs and there is ob-

(1) Coupling

(2) Fusion

(3) Fusion with zinc chloride

(4) Imide formation

tamed the intensely green dyestuff malachite green. The oxidation of the triphenylmethane compounds, generally termed leuco bases, is normally brought about by means of freshly prepared lead peroxide, PbO_2 , but other oxidizing agents can be employed, atmospheric oxygen in some cases being sufficient. Malachite green is made in the following manner

acetate) are required to facilitate the process, and, on occasion catalysts must be used to bring about condensation. The following examples will not only illustrate these reactions, but will explain actual processes by which many dyestuffs are made from intermediate products.

The condensation process illustrated by (1) in the foregoing examples, and designated as coupling, is generally carried out at temperatures between 0°C and 20°C , and under weakly acid or alkaline conditions. The time for the completion of the reaction may vary from one hour to five days, depending upon the reactivity of the diazo or tetrazo compounds and of the intermediates with which they are being coupled. The products are azo dyestuffs.

The fusion of benzanthrone to violanthrone, as illustrated by (2), is generally carried out under anhydrous conditions and with the addition of a material to lower the melting point of the caustic potash. Anhydrous alcohol or aniline is used for this purpose.

In order that complete reaction may be obtained between resorcinol and phthalic anhydride as illustrated by (3), anhydrous zinc chloride must be used. The product obtained, fluorescein, is tinctorially among the most powerful of the coal tar dyes, inasmuch as extremely low concentrations of its sodium salt exhibit intense yellow colour with a greenish fluorescence.

The process by which condensation of a chloroanthraquinone with an aminoanthraquinone as illustrated by (4) was not discovered until 1903. The reaction, named for F. Ullmann, who discovered it, is best brought about by heating the intermediates together in a high-boiling solvent, such as dichlorobenzene or nitrobenzene, and in the presence of an acid acceptor and of a trace of copper or of one of its salts as a catalyst.

The process of oxidation is employed for the manufacture of a large group of dyestuffs whose parent compound is triphenyl

Frequently, oxidation is employed to bring about condensation, *i.e.*, to tie together molecules of two or more intermediates by the removal of hydrogen. A perfect example of this procedure is found in the manufacture of safranin T, where molecular quantities of *p*-toluylenediamine, *o*-toluidine and aniline are oxidized together to form the dyestuff, the first step in the process being the formation of the indamine

¹ Strictly speaking, the products are anthraquinonyl amines but the dyestuff literature invariably refers to them as imides.

In dyestuffs derived from anthraquinone, the hydroxyl group ($-OH$) plays an extremely important role in colour formation. In some cases this group is introduced by fusion of the sulphonic acids with $NaOH$ or $Ca(OH)_2$ although in others it is obtained by direct oxidation. When anthraquinone β -odium sulphonic acid is fused in an oxidizing mixture of sodium hydroxide and sodium nitrate, 1,2-dihydroxyanthraquinone, the dyestuff known for centuries as alizarine results. If this compound is further oxidized by means of alkali (forming sulphuric acid), a reaction discovered by Reine Böhm in 1902, there is obtained a range of dyestuffs the shade of which varies with the number of hydroxyl groups introduced.

In a number of cases in dyestuff manufacture, hydroxyl (OH) and carbonyl ($COOH$) groups have to be protected, that is, rendered nonionic, in order to obtain desired properties of dyeing or fastness. The reaction by which this is accomplished is generally termed esterification, although chemically it would be a more exact term when the reaction is applied to hydroxy compounds. Dihydroxyviolanthrone is a poor dyestuff being fugitive to light and bleaching agents. However if the hydroxyl groups are etherified by means of dimethyl sulphate the dimethyl ether, an exceedingly fast green dyestuff, sold under the name of jade green, is obtained. (See *Intraquinone Compounds*.)

Esterification can also be illustrated by the process by which rhodamine 6G is made. Here two moles of ethyl-*m*-aminophenol are condensed with one mole of phthalic anhydride and the thus obtained base is esterified with ethyl alcohol, sulphuric or hydro

chloric acid being used as the esterification catalyst. With the latter acid the reactions are as follows:

By halogenation is meant the introduction of chlorine or bromine into a dyestuff molecule. Usually in the carrying out of the process, the dyestuff is dissolved or suspended in a solvent such as acetic acid, dichlorobenzene or nitrobenzene, and the chlorine or bromine is added directly at ordinary or elevated temperature. The process invariably brings about a marked change in the shade of a dyestuff, and thus the halogen atoms can be considered as auxochromes. Halogenation is most widely applied in the manufacture of indigo and anthraquinone dyestuffs, although it was applied as early as 1874 in the preparation of eosine by the bromination of fluorescein to its tetrabrom derivative.

In the case of the anthraquinone vat colouring matters, it is usually impossible to represent with certainty the position of the hydrogen atoms entering the molecule. But in the particular example given for anthraquinone derivatives an accurate representation can be made, since dichloroanthrone can be made by another method whereby the positions of the chlorine atoms are definitely established. The product is the fastest, bright blue dye-stuff known for dyeing cellulose fibres, cotton dyed with it can be subjected to the action of dilute hypochlorite solutions without materially changing the shade of the dyings.

Classification—It has already been shown that the hydrocarbon skeleton of the dyestuff molecule is primarily responsible for the existence of colour. This skeleton, therefore, affords a basis for chemical classification. The auxochrome groups clothe the skeleton to give the molecule distinctive properties which, among other things, determine the method by which the dyestuff is applied. A dyestuff molecule of almost any class may be given basic or acidic properties by the introduction of amino (NH or $\text{N}(\text{CH}_3)_2$), sulphonic (HSO_3) or hydroxyl (OH) groups, and these properties influence the methods of dyeing as well as determine the shade and fastness properties of the dyestuff. Because of these facts, the dyestuffs will be classified in two ways: (1) according to chemical structure, and (2) according to method of application.

CHEMICAL STRUCTURE AND COMMERCIAL ASPECTS

Since their introduction and original use in the 19th century, a number of synthetic dyestuffs belonging to miscellaneous classes have become obsolete in the 20th century. For this reason, only those classes common in world trade subsequent to the ending of World War I are included here. The system of chemical classification employed by the United States Tariff Commission, taken from the authoritative *Colour Index*, a publication of the Society of Dyers and Colourists of England, is used in this article.

Nitroso Compounds—Typical structure

This class of compounds having the orthoquinoid chromophore is relatively unimportant, only a few members being made and used. These dyes are derived by the action of nitrous acid upon phenols or naphthols and their sulphonic acids. The products are used in the form of their insoluble iron salts as pigments. Such salts are generally termed 'lakes' and are employed in the paint or ink trade.

Nitro Compounds—Typical structure

This class is also relatively unimportant, naphthol yellow S being its best-known member. This dyestuff is made by the action of nitric acid upon nitroso 1-naphthol 2, 7 disulphonic acid, and is marketed as the disodium or dipotassium salt of 2, 4-dinitro 1-naphthol-7 sulphonic acid, which has the following structure.

Azo Compounds—Typical structure $\text{R}-\text{N}=\text{N}-\text{R}'$, in which R and R' stand for substituted phenyl, tolyl, xylyl and naphthyl radicals. Numerically, this is by far the largest class of dyestuffs, almost 600 individual products being listed in the *Colour Index*

as against a total listing of 1,250 for all classes of synthetic colouring matters. A very shade of colour from the lightest yellow to the deepest black can be obtained from the members of this class, and because of wide variations in chemical constitution the dye-stuffs of the group exhibit a wide range of properties, particularly as to methods of dyeing, applicability to various fibres, fastness, etc.

When the chromophore grouping $-\text{N}=\text{N}-$ occurs but once in the molecule, the products are termed monoazo dyes, when twice, diazo, and thrice triazo. A few products containing four of the azo linkages and termed tetraazo are known, but they are relatively unimportant. The simpler constituents of the group, the monoazos, are generally yellows, oranges and reds, while the diazos and triazos are generally browns, greens, blues and blacks.

As far as production and sales in world commerce are concerned, direct black E is the most important dyestuff in the azo group. About 6,700,000 lb. were sold in the United States alone in 1949, the average sales price being 30 cents a pound. It is used primarily for the dyeing of cotton in dull black shades. No mordant is required for such dyings, hence, the term 'direct'. It is made from four intermediates, benzidine, H acid (1-amino-8-naphthol 3, 6 disulphonic acid), aniline and m-phenylenediamine, and contains three azo linkages. The following figure will illustrate the manner in which the dye molecule is built up.

In making this dyestuff, benzidine is first tetrazotized and coupled with a molecular proportion of H acid in acid solution. Aniline is then diazotized and coupled to the opposite side of the H acid molecule in alkaline solution. Finally, m-phenylenediamine is coupled under alkaline conditions with the free diazonium group in the benzidine nucleus. The reaction mass is then made slightly acid, and the dyestuff is obtained by filtration, a sufficient concentration of sodium chloride or sodium sulphate—resulting from the use of both alkaline and acid conditions—being present to render the dyestuff insoluble. In many cases in the manufacture of azo dyestuffs, sodium chloride or sodium sulphate must be added at the end of the process to bring about separation of the product from solution. This procedure is termed 'salting out.'

Direct black E also illustrates an extremely important principle which characterizes certain of the azo dyestuffs. In 1884 it was found that colouring matters which contained the benzidine nucleus were "substantive" to cotton, i.e., that they could be used in the dyeing of cotton without the assistance of a mordant. Congo red, a diazo compound made by coupling two moles of naphthionic acid to one mole of tetrazotized benzidine, was the first dyestuff of the class. Within 20 years, at least 100 of these direct colours were brought into world commerce, direct black being discovered in 1901. The dimethyl and dimethoxy derivatives of benzidine, called toluidine and diamidine, respectively, imparting this same substantivity to the azo dyestuffs derived from them, became intermediates of extreme importance in the dyestuff industry.

In the decade following World War I, another class of azo dyestuff came into prominence. As early as 1880 it had been found that cellulose fabrics could be dyed in brilliant red shades by first impregnating cloth with β naphthol and then passing it through a cold solution of diazotized nitroaniline, the coupling of the two intermediates taking place on the cloth. Alternatively, the β naphthol could be applied to the cloth in patterns, in which case prints could be obtained. But the dyestuff, called para red, in spite of its insolubility in water, was somewhat fugitive to light and washing. Nevertheless, it became the parent of a line of comparatively fast dyestuffs, for, in 1912, it was discovered that dyings and prints of a brilliant red shade and of considerable fastness could be obtained if the anilide of 3 hydroxy-2-naphthoic acid was substituted for β naphthol in the process. The dyestuff

formed in this manner is called naphthol red, its relationship to para red being as follows

Thus, the amide of 3-hydroxy-2-naphthoic acid became the first of a long series of arylumino hydroxynaphthoic acids which were later developed. The Germans called such intermediates naphthols, Imperial Chemical Industries, Ltd., in England brentnols, and du Pont and Calco in the United States naphthamils and naphthols respectively.

The three largest selling compounds of the group, is of the end of World War II, were

When these products were first used for the dyeing and printing of fabrics, aromatic amines and their salts (for example, diarsidine or 4-chloro-2-aminotoluene hydrochloride) were marketed with them, to be diazotized and coupled with them where and when the dyestuff was to be applied. This method of application has continued. But later another group of products was added to the line, the dyestuff manufacturers marketing the amino derivatives in the form of their diazo salts sufficient stabilization for commercial usage being achieved generally by the formation of double salts of the diazo compounds. For this purpose inorganic materials such as zinc chloride can be used. The textile mills were thus relieved of the necessity of diazotizing the amino compounds, a simplification much desired by them.

In the decade 1930-40 another innovation along this line became prominent in the printing of textile fabrics, for it was found that diazo compounds can be "stabilized" to so great an extent that they may be marketed safely in the form of mixtures with the arylumino hydroxy-naphthoic acids. When applied to fabrics by regular textile dyeing or printing methods, such products give no colour until the impregnated fabric is subjected to treatment with an acid whereby the stabilized diazo salt is broken down and the active diazo group is regenerated. When this occurs, coupling immediately takes place with colour formation. In this case stabilization is achieved by treating the diazo compounds with secondary amines containing a water-solubilizing group, sarcosine being an ideal substance for the purpose. The reaction taking place can be illustrated as follows:

In Germany the Interessen Gemeinschaft Farbenindustrie (the I.G.) marketed these mixed products under the name of rapidogens, in England Imperial Chemical Industries, Ltd., called them brentnogens, and in the United States the du Pont company called them dregens. A full range of shade from light yellow to deep black in azo dyestuffs of this class was available in world commerce at the conclusion of World War II.

Many of the azo dyestuffs are valuable only when applied with a chromium mordant. Obviously, therefore, it would seem to be advantageous to combine the chromium with the dyestuff molecule and to market the thus formed chromium complexes. In the decade 1920-30 a full range of such products came into world trade, and at the conclusion of World War II, the line had achieved a prominent position in the dyestuff industry. The Society of Chemical Industry of Switzerland called the products neolans, the German I.G., palatine fasts, Imperial Chemical Industries in England ultralans, and Calco and du Pont in the United States, calco fasts and chromacils, respectively. The exact chemical structure of the compounds had not been definitely established by 1950 although it seemed fairly certain that the chromium is bound by hydroxy groups in the dyestuff molecule.

The stilbene series comprises a special class of dyestuffs containing the azo group. These products are made, without the employment of the diazo reaction, by the intramolecular rearrangement and self condensation of *p*-nitrotoluene *o*-sulphonic acid. When this acid is submitted to the action of aqueous caustic soda, a yellow dyestuff, direct yellow R, is formed.

By modification of the treatment of *p*-nitrotoluene *o*-sulphonic acid with caustic soda, a variety of these stilbene dyestuffs can be obtained. They dye cellulose fibres directly and are faster to light than other azo dyes. They also behave differently with reducing agents, for instead of being at once split into colourless compounds, they give at first hydrazo compounds which can be reoxidized to the stilbene dyestuff.

Another class of azo dyestuffs should be mentioned briefly. This is the group of azo derivatives made and sold for the purpose of colouring oils. The members of the group are simple monoazo compounds, oil yellow, for example, being diazotized aniline coupled with dimethylaniline, and oil red, diazotized α -naphthyl-

amine or mixed xylenes coupled with β naphthol. They contain no water solubilizing groups and are not useful, therefore, in the dyeing of textiles. In the United States, large quantities of these oil dyestuffs are produced and used for the colouring of gasoline.

The property possessed by azo dyestuffs of being readily transformed by strong reducing agents into colourless compounds is of great value in the printing of textiles. In the production of so-called "discharge" or "foulard" styles, materials consisting of cotton, silk or artificial fibres, which have been dyed in solid shades with appropriate azo dyes, are printed with a thickened reducing agent which may or may not contain an indigo or anthraquinone vat dyestuff. When the cloth is then steamed, the azo dyestuff is discharged, leaving a white pattern upon a coloured ground, or, if a vat colour was incorporated into the reducing agent, a coloured pattern upon a coloured ground of another shade.

This property of easy reduction possessed by the azo dyestuffs is extremely valuable in other directions, affording as it does (1) an accurate method for the measurement of the concentration of dyestuff either in solution or on a fibre, and (2) a relatively simple method for determining the intermediates used to build up azo dyestuffs. Under the action of reducing agents the azo linkage $-N=N-$ is broken with the formation of two amino compounds which usually can be separated and identified. Thus, orange II, the formula for which has already been given, splits into sulphonic acid and 1 amino 2 naphthol.

The azo dyestuffs and the arylaminohydroxynaphthoic acids occupy such an important position in commerce that a few statistics as to production and sales should be considered. The figures given in Table I are taken from a report of the Tariff commission of the United States, the only country publishing such detailed information. It can be assumed that in world commerce the importance of the 12 products listed is proportional to production and usage in the United States. Moreover, a rough approximation of world production of these 12 products might be obtained by multiplying the United States production by four.

TABLE I—U.S. Production and Sale of Azo Dyestuffs, 1949

Dyestuff	Production (in thousands pounds)	Sale		
		Quantity (in thousands pounds)	Value (in thousands dollars)	Value (Dollars per pound)
Chrysoidine Y	466	457	248	54
Sudan I	319	348	287	83

Naphthol AS SW	360	377	689	2 02

Pyrazolone Compounds—Characteristic grouping

where R' is a substituted benzene or naphthalene nucleus, R³ is a substituted or unsubstituted benzene nucleus and R⁴ is CH₃ or COOH

The most important dyestuff of this comparatively small class is tartrazine, a bright lemon yellow, which is made by the condensation of two moles of phenylhydrazine sulphonic acid with one mole of dioxypyrazole in acid solution. Xylene light yellow, made by coupling diazotized sulphanic acid to dichloro sulpho-phenyl-methylpyrazolone, and chrome red B, made by coupling

diazotized 1 amino-2-naphthol-4 sulphonic acid to phenylmethylpyrazolone, are the two other important dyestuffs of the class.

Ketorimine Compounds—Only one dyestuff, auramine, belonging to this class is of commercial importance. It is made by heating together a mixture of tetramethyldiaminodiphenylmethane, sulphur and ammonium chloride under pressure of gaseous ammonia. The dyestuff, used primarily for dyeing paper pulp in bright yellow shades, possesses the following structure

Triphenylmethane Compounds—Characteristic grouping

in which R stands for a substituted or an unsubstituted benzene or naphthalene nucleus. Crystal violet and methyl violet are the best known and most widely used dyestuffs of this class, the first being made by the action of phosgene upon dimethylaniline, the latter simply by the oxidation of dimethylaniline, usually by means of cupric salts. They are used primarily in the paper industry, either for colouring paper pulp or for the coating of copying paper, i.e., carbon paper.

The triphenylmethane dyestuffs are characterized by brilliant and intense shades of red, violet, blue and green. They have basic, acidic and substantive properties according to the auxochromic groups they contain. As a class they are rather deficient in fastness to light, and frequently also to washing and to alkalis, by which they are partly decolorized. This loss of colour is attributed to a change of type from a quinoid to a carbonyl structure, and it can be diminished by the introduction of a chlorine atom or a sulphonic or other group into one of the benzene nuclei in the ortho position to the central carbon atom. Thus, setoglaucine, made from *o*-chlorobenzaldehyde and dimethylaniline, is a somewhat faster dyestuff than malachite green, which, as has been shown, is made from benzaldehyde and dimethylaniline.

Other important basic dyestuffs of this class are magenta, the brilliant greens and the Victoria blues, while the most important acid members are the acid greens, acid violets, patent blues, the acid glaucines and xylene blues. A few compounds of the class are especially valuable as chrome-mordant dyestuffs and they are generally designated as the chrome azurols and the chrome cyanines. Their chromium fixing property is attributed to the presence of carboxyl groups in the molecules.

In Table II are given the production and sales of six important dyestuffs of this class in the United States.

TABLE II—U.S. Production and Sale of Triphenylmethane Dyestuffs, 1949

Dyestuff	Production (in thousands pounds)	Sale		
		Quantity (in thousands pounds)	Value (in thousands dollars)	Value (Dollars per pound)
Malachite green	216	273	447	1 64
Acid glaucine blue	646	840	850	1 02
Methyl violet	1 247	1 702	920	84
Crystal violet	812	1 118	1 344	1 07
Acid violet	97	143	186	1 35
Victoria blue B	154	198	414	2 14

Xanthene Compounds—Characteristic grouping

This class made up of both basic and acidic members, comprises several of the most brilliant dyestuffs available in commerce. They differ from the triphenylmethanes in that two of the benzene nuclei of the molecule are joined by an oxygen bridge, and to this characteristic can be attributed their greater resistance to oxidizing and reducing agents, and therefore their fastness to all dyes, soap and mangle (mechanical action whereby a woven fabric is softened and felted). The basic members, the fluoresceins, are made by the condensation of methyl or ethyl substituted aminophenols with phthalic anhydride whereas the acidic members, the rhodamines, result from the condensation of resorcinol with phthalic anhydride, or with chloro-substituted phthalic anhydrides. The red rhodamines, of little commercial importance, are sulphonic salts of the basic members of the series.

The two most important members of the class are rhodamine B and eosine (although, as has been observed, fluorescein became a highly important product in World War II). The relationship of the three compounds is illustrated as follows:

Although the rhodamines are used primarily for the dyeing of silk in brilliant pink and red shades and for the preparation of water-soluble salts which are used as pigments, eosine itself is used almost exclusively for the latter purpose, its acid salt being an extremely bright bluish red pigment with a high, bronzy over-tone (reflexion). The rhodamines, in especially purified forms, are also used in the cosmetic trade; any given lipstick or face powder, for example, is most likely to be coloured with a rhodamine or a pigment derived from a rhodamine.

The phloxins and rose bengals are bromo and iodo derivatives, respectively, of the condensation products of chlorophthalic anhydrides and resorcinol. They are no longer of any considerable commercial importance.

Acridine Compounds—Characteristic grouping

This is a small class of yellow and orange dyestuffs with basic properties which are used mainly for the dyeing of leather and other members of the class are occasionally printed on textiles. The chief representatives are phloxine, acridine orange and acridine yellow. Proflavine and acriflavine, members of the class are useful in medicine as local antiseptics, but they are not used as dyes. The members of the group are more resistant to the action

of reducing agents than the azos, the triphenylmethanes and the xanthenes, and are therefore not readily decolorized by sodium hydrosulphite.

Quinoline Class—No characteristic grouping can be given for the dyes of this class although the quinoline nucleus is common to its members. Only one or two representatives of the group are useful for the dyeing of textiles. These are the quinoline yellow made by condensing quinoline (2-methylquinoline) or a derivative of this compound with phthalic anhydride and sulphonating the resulting quinophthylones, for example:

From the fact that either the mono- or disulphonic acid of quinophthalone yields unsubstituted phthalic acid upon oxidation it appears that sulphonation takes place in the quinoline nucleus of the compound.

A number of dyestuffs belonging to this class are of primary importance in the art of photography. These products, designated as the cyanines, are characterized chemically by structures in which two nitrogen atoms are members of heterocyclic ring systems, and in which the chain joining the nitrogen atoms passes through 1 part of each ring. Pracyanin, for example, discovered in 1905, and made by condensing two moles of ethyl quinidium iodide with formaldehyde, has the following structure:

The value of the cyanines in the art of photography is based on their properties of sensitizing silver bromide emulsions to various wave lengths of light. Thus, by increasing the chain length between the quinoline nuclei in dyestuffs possessing the foregoing structure, sensitivity is shifted toward the red end of the spectrum, and by decreasing the chain length, the sensitivity is shifted in the opposite direction. Moreover, either one or both of the quinoline nuclei can be replaced by other ring systems in which the nitrogen atoms are part of the ring, for example, by (1) thiazole, (2) benzo-thiazole and (3) alkylquinoline.

Thus, by varying the nuclei in the cyanine and the chain length between the nuclei dyestuffs can be prepared which sensitize photographic emulsions in the invisible as well as in the visible ranges of the spectrum.

Azine Compounds—Characteristic grouping

This class contains both basic and acidic dyestuffs with shades ranging from red to blue, the basic members including the red saframines and the blue or black spirit-soluble indulines and nigrosines, and the acidic members including the rosindulines, the water-soluble indulines and nigrosines, the indocyanines and the acid cyanines. Perkin's mauve, the first dyestuff manufactured from coal tar, is a member of this class, and is closely related to safranine, the method of preparation and formula of which have already been given. The saframines are used primarily for the printing

of cheap cotton fabrics and for the dyeing of paper pulp, while the indulines and nigrosines are employed primarily for the dyeing of leather, the spirit soluble brands being the dyestuffs mainly employed in black shoe polishes.

Aniline black, an insoluble dye formerly employed widely in the cotton industry but now largely supplanted by other colouring matters is a member of this class. It was formed by impregnating cloth with an aniline salt and then subjecting the material to the action of a strong oxidizing agent such as a chlorate or a chromate, the fastness of the black dyeings or prints being dependent upon the vigour of the oxidation.

In general, it can be said that the azines result from the oxidation of various aryl amines, nigrosine, for example, being prepared by oxidizing a mixture of aniline and aniline hydrochloride, by means of either nitrobenzene or a nitrophenol at 180–200° C.

Oxazine and Thiazine Compounds—These classes are closely related to the azines, the former having an oxygen atom and the latter a sulphur atom in place of one of the nitrogen atoms in the azine structure. Only a few dyestuffs of these classes are important commercially. New blue R (Meldola's blue) is a representative oxazine, while methylene blue is a thiazine. The former is made by the condensation of *para*-nitrodimethylaniline and β naphthol, while the latter results from the oxidation of a mixture of dimethylaniline and dimethyl *p*-phenylenediamine in the presence of sodium thiosulphate. The dyestuffs have the following formulas:

Other dyestuffs of the oxazine class are nile blue, the galcoyanines and the anthracyanines. The brilliant alizarine blues are thiazines. The colour of the blue and black dyestuffs of the sulphide class is attributed to the thiazine chromophore, although the complete structure of the compounds is not known.

Thiazole Compounds—Characteristic grouping

One of the most important dyestuffs of this class is primuline, in which the thiazole group occurs twice.

It is made by the sulphonation of the product which results when *p*-toluidine and sulphur are heated together at temperatures of 220°–270° C., the 'primuline base' usually being directly distilled under vacuum from the reaction mass. The dyestuff can be applied to cotton without a mordant, whereupon dyeings of a primrose yellow shade are obtained, or, inasmuch as the molecule contains a free amino group, the dyestuff can be diazotized on the fibre and coupled there with a suitable second component. Thus, with β naphthol, a brilliant red is obtained on cotton, the colour being fast to washing.

In the manufacture of primuline base varying amounts of dehydrothio *p*-toluidine are formed as a by-product. On occasion, however, the primuline base is the by-product, for, by the methylation of dehydrothio *p*-toluidine, the brilliant yellow dyestuff, thio flavine T, another thiazole, particularly useful as the source of an important yellow pigment, is produced.

Indigoid Compounds—Characteristic groupings

Until 1905 this class of dyestuffs was represented only by indigo itself, its isomeric indorubin, and its sulphonic acid indigo carmine. Prior to the beginning of the 20th century, indigo was obtained by fermentation of the expressed sap of the *Indigofera tinctoria* and other similar plants growing in India, Java, etc. Indorubin always being associated with the more important dyestuff. The manufacture of synthetic indigo in Germany, perfected in the last few years of the 19th century, was an economic upheaval of the first order, for in India alone more than 1,500,000 acres of land were devoted to the culture of the indigo plant. By the time World War I began, the synthetic product had almost completely supplanted the natural, Germany and Switzerland supplying the great bulk of world requirements.

In the years between 1880 and 1900, a number of methods were developed by the Germans for the synthesis of indigo, but none of these was economically successful until the phenylglycine-sodamide process was perfected in 1896–97. In this process, phenylglycine is fused in a mixture of caustic soda, caustic potash and sodamide, the function of the latter substance being to bind the water formed in the fusion and thus to maintain anhydrous conditions in the reaction mass. An almost quantitative yield of indoxyl is obtained by this method, and this substance in turn is quantitatively converted into indigo by simply aerating the "drowned" fusion mass (fusion mass suspended in a large volume of water), atmospheric oxygen being sufficient to effect dyestuff-formation from the indoxyl-sodium salt. The reactions involved are as follows, the indoxyl being shown as the free acid for simplification.

During World War I the manufacture of indigo was undertaken in Great Britain and the United States, and, following that war, both of those nations began exporting the dyestuff. Table III will illustrate the growth and decline of the manufacture of indigo, 20% paste, in the United States, the only country where data on production and value are available.

TABLE III.—U.S. Production and Value of Indigo, 20% Paste

Year	Production (in thousand pounds)	Value (Dollars per pound)
1916	none	—
1917	275	1.42
1918	3,084	58
1919	8,361	59
1920	18,178	74
1921	20,122	10
1922	21,333	74
1923	13,614	17
1924	11,133	16
1925	13,396	21

As of the beginning of World War II, Germany, Switzerland, France, Italy, the U.S.S.R., Japan and the United States were all producing their own requirements of indigo, the three principle exporting countries being Germany, Great Britain and the United States, with the bulk of the exports going to China. In the United States particularly, the importance of the dyestuff began a rapid decline in the decade 1920-30, for faster colouring matters began to be preferred even at a somewhat increased cost per yard of material dyed.

By the halogenation of indigo, chloro and bromo derivatives can be obtained, and several of these have become important dyestuffs in commerce. Thus 533,000 lb of tetrabromindigo 16% paste, given various names depending upon the manufacturer, but generally named bromindigo blue 2B, were sold in the United States in 1949.

Indorubin, whose sulphonic acid was once used as a red colouring matter for wool, of itself never became an important dyestuff. The same holds true for many products with the indorubin configuration which have been synthesized. Its relationship to indigo can be understood from its chemical structure.

In 1906 thiondigo, the first of a large series of indigoid dyestuffs containing sulphur and giving orange, red and brown shades, was discovered by P. Friedländer in Germany. The relationship between these compounds and the true indigos can be seen by the formulas of the three most important dyestuffs in the series.

These thiondigo dyestuffs are most usually prepared by the ring closure of a thioglycolic acid to a thiondoxyl, and the oxidation of the thiondoxyl to the dyestuff by means of a mild oxidizing agent.

The relative importance of two of these thiondigo dyes can be realized by a consideration of their sales volume and value as against indigo itself in the United States in the year 1949.

TABLE IV—U.S. Production and Sale of Thiondigo Dyestuffs, 1949

Dyestuff	Sale or production (in thousand pounds)	Value (Dollars per pound)
Indigo 10% paste	13,306	2.11
Thiondigo red 3B 10% paste	208	1.34
Thiondigo orange R 10% paste	111	1.40

Anthraquinone Compounds—Characteristic grouping

This important class of dyestuffs contains acidic, mordant fixing and vat dyeing members. All groups, however, are characterized by the fastness of their members to destructive agents such as light, fading and oxidizing agents. The older members, comprising the alizarines, purpurines, alizarine cyanines and alizarine blues (mostly hydroxy derivatives of alizarine itself) at one time were highly important mordant fixing dyestuffs, but since the advent of other cheaper classes of colouring matters with satisfactory fastness properties their importance in world commerce has diminished almost to the vanishing point. The formulas and method of manufacture of several of these dyestuffs have already been given.

With aluminum, chromium or iron hydroxides, the hydroxy-anthraquinones produce colours which vary with the hydroxide employed. Thus, the typical dyestuff alizarine yields with aluminum a red, with chromium, a maroon, and with iron, a purple. When fixed with a compound mordant of aluminum, calcium and a fatty acid, the celebrated turkey red is produced. This colour was originally dyed by the use of madder, the ground root of the *Rubia tinctorum*, which contains alizarine, and which up to about 1875 was grown in large quantities for this purpose. The synthesis of alizarine from anthracene by C. Gräbe and C. Liebermann in 1868 laid the foundation for the artificial manufacture of this dye stuff, and also for the great developments in anthraquinone chemistry which have since followed. In a few years the natural colouring matter was entirely replaced by the synthetic, the manufacture of which was effected by oxidizing anthracene to anthraquinone, converting this into its β sulphonic acid and fusing the latter with caustic soda.

The acidic members of the anthraquinone class are represented by alizarine red, alizarine acid blues, including the blue black B acid alizarine green, alizarine saphirol, alizarine rubinol, alizarine direct blue and alizarine cyanine green. These products are used mostly for the dyeing of wool, with or without a mordant, although one of them, alizarine saphirol, is used widely for the dyeing of paper. Following is the chemical structure of three important dyestuffs of this class.

The production, sale and value of these three products in the United States in 1949 were as given in Table V

TABLE V—U.S. Production and Sale of Anthraquinone Dye stuffs, 1949

Dyestuff	Production (In thou sand pounds)	Sales (In thou sand pounds)	Value (Dollars per pound)
Alizarine saphrol	878	661	13
Alizarine cyanine green	41	258	2.63
Alizarine blue black B	102	150	1.93

The vat colouring matters of the anthraquinone series are the fastest dyestuffs known. For this reason, since World War I they have assumed the most important place, as far as dyestuffs are concerned, in the world textile industry. As of the conclusion of World War II, these dyestuffs were being manufactured in Germany, France, Italy, the U.S.S.R., Great Britain, Japan and the United States. No other single synthetic dyestuff with the exception of indigo was ever produced in greater quantities than anthraquinone vat khaki 2G during the years of World War II. In the United States alone, production reached approximately 1,000,000 lb of the 10% paste per month, with a sales value of \$1.10 to \$1.20 per pound, the product being used chiefly for dyeing cotton cloth in fast khaki shades. At this price range, the value of this dyestuff in a yard of cotton cloth dyed to the average olive drab shade was approximately five cents, about four pounds, being required per 100 yd of such cloth. Vat khaki 2G is made by the condensation of four moles of α aminoanthraquinone with one mole of 1, 4, 5, 8 tetrachloroanthraquinone by the Ullmann reaction, and the ring closure of the resulting compound called "pentanthrimide" by fusion with anhydrous aluminum chloride.

Anthraquinone vat khaki 2G

Closely related to vat khaki 2G are vat brown AR and vat olive AR, both of which, too, were produced in enormous quantities during World War II. The following series of reactions will illustrate one method by which each of these dyestuffs are made

(1)

1-Benzoylamino 5-aminoanthraquinone

1-Benzoylamino 4-chloroanthraquinone

(2)

α -chloroanthraquinone

α -aminoanthraquinone

It will be observed that vat brown AR and vat olive AR are isomeric products, dyeing cotton in entirely different shades because of the different positions of the benzoylamino groups.

The first vat dyestuff derived from anthraquinone to be marketed commercially was discovered by R. Bohn in 1901. It was made by the fusion of β aminoanthraquinone in molten caustic potash. The product of the reaction, illustrated below, is a blue powder which dyes cotton and linen fibres in bright blue shades of exceptional fastness. The dyestuff was first marketed by the Badische company under the name of indanthrene blue R. Its monochloro derivative, a somewhat greener shade of blue, soon made its appearance under the name of indanthrene blue GCD, and subsequently its dichloro derivative became an important article of commerce under the name of indanthrene blue BCS.

Other important members of the class are violet blue green and violet blue 6B (violanthrone) whose structure and methods of manufacture have already been given. In addition there are at least 50 other dyestuffs belonging to this class which are of extreme importance in the world textile industry. On the majority of these patents have expired and therefore, the products are widely manufactured (see *nomenclature* above).

The violet dye-stuff of the anthraquinone class violanthrone and its isomer, isoviolanthrone, are of particular interest chemically because of the fact that they are neither more than quinones derived from hydrocarbons of high molecular weight. The structures of the two compounds were proven by A. Zinke and R. Scholl, who synthesized them from two benzoyl derivatives of perylene as follows:

The constitution of perylene itself is also proven by R. Scholl, who synthesized it from 1,8'-diiodo-1,1'-dinaphthyl as follows:

In general it can be said that after 1900, dyestuff chemists more fully explored the field of the anthraquinone vat dyestuffs than any other.

In Table VI are given the production and sales value of a number of the important anthraquinone vat dyestuffs in the United States in 1940.

TABLE VI—U.S. Production and Sale of Anthraquinone Vat Dyestuffs, 1940

Dye stuff	Production (in thousand pounds)	Value (Dollars per pound)
Vat dark blue 6B 35% paste	11	1.8
Vat violet brown 6, 2% paste	5,395	1.0
Vat blue RS 30% paste	1,161	1.22
Vat blue C (D) 51% paste	1,770	1.2
Vat olive B, 1% 1/2% paste	1,159	1.01
Vat brown R 12% 5% paste	861	1.7
Vat khaki 20% 10% paste	800*	1.35

*Approximate figure

Phthalocyanine Class—The structure of compounds belonging to this class has already been given (see *Theoretical*, above). The metallic phthalocyanines are prepared primarily by two methods. Copper phthalocyanine, for example, is made (1) by heating together a mixture of anhydrous cuprous chloride, ordinary salt and phthalonitrile (o dicyano benzene) or (2) by heating together a copper salt, urea and phthalic anhydride. The products, insoluble in water and intensely blue in colour, are used mostly as pigments. Although sulphated copper phthalocyanine is occasionally used as a bright blue dyestuff for the direct dyeing of cotton and rayon.

By the chlorination of copper phthalocyanine, various chloro derivatives can be obtained, the most important ones being the compounds containing 12-16 chlorine atoms in the molecule. These products are intensely green in colour. Moreover, they are remarkably stable. For these reasons they, too, have become of extreme importance in the pigments industry.

The production of phthalocyanine blue in the United States in 1940 was 609,000 lbs. with a sales value of \$3.36 per pound.

Sulphide Class—As has been previously noted, a large class of dyestuffs can be made by subjecting various intermediates and products to the action of sulphur, or sodium sulphide, or both, the process being known as thionation. Furthermore, in some cases the reaction is carried out by simply heating the intermediates and sulphur together, whereas in others, solvents such as water and alcohol are employed. By this reaction, sulphide colouring matters were once made from materials such as sawdust, straw or sulphite cellulose, but these dyestuffs have long since been replaced by others derived from definite benzene, toluene and naphthalene intermediates. Thus, by heating ("baking") sulphur and *m*-toluylenediamine together at temperatures from 230° to 260° C. and treating the reaction product with aqueous sodium sulphide, a deep brown dyestuff, used in large quantities for the dyeing of cotton, is obtained. By subjecting diminophenol or a mixture of diminophenol and trinitrophenol (picric acid) to the action of aqueous sodium sulphide in which sulphur has been dissolved (sodium polysulphide), deep black cotton dyestuffs are manufactured in large quantities, the shade of the black dyeings becoming progressively redder with increasing amounts of picric acid. By boiling under reflux in alcoholic solution of sodium polysulphide and the leucodimophenol derived from carbazole, an important blue cotton dyestuff, generally named hydron blue, is obtained, the leucodimophenol being made by the following reaction:

Finally, by thionating in ethyl alcohol the azine derived through the indamine from *p* aminophenol and *m* toluenylenediamine, boldauve coloured dyestuffs are obtained, the reactions leading to the azine being illustrated as follows

Formulas for the sulphide dyestuffs cannot be written, for in no case has the constitution of the compounds been clearly established

The production and sales value of the most important of the sulphide dyes in the United States in 1949 were as shown in Table VII

TABLE VII—U.S. Production and Sale of Sulphide Dyestuffs, 1949

Dyestuff	Production (In thousand pounds)	Value (Dollar per pound)
Sulphur black	0 365	21
Sulphur blue	2 395	40
Sulphur brown	2 798	28
Sulphur green	1 266	73
Sulphur yellow	450	45

White Dyestuffs—In the early years of World War II, the German I.G. filed patent applications in a number of European countries on the use of certain derivatives of diaminosilber disulphonic acid as white dyestuffs. The applications covered the use of the products (1) in washing compositions to improve the brightness of textile fibres washed therewith, (2) in papermaking for brightening the pulp, (3) in textile printing for whitening the discharged parts of the prints, and (4) in plastics and extruded synthetic fibres for whitening these materials.

Nothing much was done with the development during the years of the war. At its conclusion, however, possibilities in the foregoing directions evoked great interest in Switzerland, Great Britain and the United States. In Germany the products had been designated as the blankophors, in those other countries they began to appear in 1946 as articles of commerce under various trade names. Thus, blankophor R, which might be considered a representative product of the group, is the compound and is made by

the condensation of two moles of phenylisocyanate with one mole of diaminosilber disulphonic acid. Other members of the group are made by condensing substituted aromatic carbonyl chlorides with diaminosilber disulphonic acid.

These whitening compounds are dyestuffs in the sense that they are substantive to fibres just as the coloured dyestuffs are substantive. Their virtue as whitening agents lies in the fact that they strongly absorb ultra-violet light and emit a large part of this energy in the visible regions of the spectrum. By 1947 they were finding important uses in textile and related fields.

METHODS OF APPLICATION

In the previous section the synthetic dyes were classified from the standpoint of their chemical structure. It is now proposed to classify them according to their dyeing properties which, as has been pointed out, are dependent to a great degree upon these structures. In the different categories, representatives of several chemical classes will frequently be found.

Basic Dyes—The basic dyes are salts, usually hydrochlorides and sulphates, of coloured bases containing amino or substituted amino groups such as NH_2 , $\text{N}(\text{CH}_3)_2$, $\text{NH} \text{C}_2\text{H}_5$, etc. They dye materials of animal origin—wool, silk, leather, feathers, etc.—directly from a neutral bath, but they have little or no affinity for materials of vegetable origin. However, they can be applied to fibres such as cotton or linen by the use of mordants, tannin and a metallic salt such as tartar emetic, or a synthetic agent such as a sulphurized phenol, being used for this purpose. The function of the mordants in this case is to produce water-insoluble complexes of the dyestuffs which are held mechanically or chemically by the fibres. If material so dyed is boiled with dilute caustic soda saturated with salt, the complexes are broken and the dye base is released. It can then be extracted from the dyed material by means of dilute acid. This affords an easy method of determining if a fibre of vegetable origin has been dyed with a basic dyestuff.

The affinity of these colouring matters for materials of animal origin is doubtless caused by chemical combination between the amino groups of the dyestuff and carboxylic acid (COOH) groups in the silk, wool, etc. Consequently, the maximum affinity for these fibres is exerted in a neutral or slightly alkaline bath, and this characteristic explains why these dyestuffs can readily be removed from such fibres by boiling the dyed materials with weak acids.

The best test for distinguishing basic dyestuffs from other classes is the formation of an insoluble coloured compound upon adding tannic acid and sodium acetate to a solution of the dyestuff. The most important members of this class are magenta, methyl violet, malachite green and brilliant green of the triphenylmethanes, rhodamines B and 6G of the xanthenes, safranin of the azines, Meldola's blue of the oxazines, methylene blue of the thiazines and chrysoidine and Bismarck brown of the azos.

Acid Dyestuffs—These dyestuffs are salts, usually the sodium salts, of coloured compounds containing acidic groups, especially the sulphonic acid group, SO_3H . They dye animal fibres, silk and wool particularly, directly from an acidified solution, and they, therefore, find their chief outlets as colouring matters for these materials. However, a number of them are much used in the form of their insoluble salts as pigments, the barium salt precipitated upon a mineral base being most generally employed. Certain acid dyestuffs of the azo class, the lake reds and lithol reds, are manufactured especially for this purpose.

Most of the important acid dyes are azos, triphenylmethanes or anthraquinones. Metanil yellow, orange II, the acid scarlets and amido naphthol red 6B are azos, alkali blue, soluble blue, the patent blues, the acid violets and acid greens are triphenylmethanes, and alizarine sapphrol, alizarine insol, alizarine cyanine green and alizarine rubinol are anthraquinones. With the exception of the anthraquinone derivatives, these dyestuffs are relatively fugitive, and they, therefore, have gradually given way to superior products.

Mordant Dyes—These are coloured compounds which of themselves have either little affinity for fibres of various sorts or poor fastness qualities when applied, but which are capable of being used as dyestuffs when "fixed" upon materials by means of a third component used in the dyeing operation. This third component is termed a mordant. The most common ones in use are various chromium salts and tannic acid, although, as previously noted, a number of so called synthetic mordants have been developed since 1900.

The role played by these mordants in the art of dyeing has never been fully established. In some cases cloth or yarn is treated with the mordant before the dye is applied, in others, the mordant is used along with the dye, while in still others, the dye is first applied and the dyed cloth or yarn is treated with the mordant. With a chromium salt as the third component, the three methods are referred to, respectively, as bottomchrome, metachrome and topchrome dyeing.

The dyestuffs applied with chromium as a mordant are usually characterized by the presence of a hydroxy group in the ortho position to a COOH , an SO_3H , an NH_2 or an $\text{N}=\text{N}$ group in the dyestuff molecule. There is much evidence to indicate that

vious metals form chelate compounds with such molecular structures (that is, ring compounds with co-ordinate valence in the ring), for example

which represents the metallic complex of alizarine with which turkey red is dyed in part. These chelate compounds are generally insoluble in water, and the role of metallic salts as mordants has been attributed to this property. Yet there is more to the mordanting operation than the formation of insoluble compounds, for as has already been shown, certain chromium-containing dyestuffs which are water soluble, have become important commercial

With the dyestuffs containing basic radicals such as NH_2 , N^+CH_3 or $\text{N}^+\text{CH}_2\text{CH}_3$, tannic acid forms relatively insoluble tan-
nates in practically all cases. Before the advent of the vat dyestuffs and the naphthols, cotton was commonly dyed or printed with the basic dyestuffs and a tannin mordant, the triphenyl methane and azo colouring matters being generally used for the purpose. But the shades thus produced were somewhat inferior in fastness to those obtained with the vat dyestuffs and with the insoluble azo dyes derived from the arylamino 2-hydroxy 3-naphthol acids.

Although many mordant dyestuffs are not greatly altered in shade by combination with the mordant, in some cases a complete change of colour is produced. Thus, the yellow alizarine gives a red and purple, respectively, with aluminum and iron salts as mordants, whereas the red azo dyestuffs derived from chromotrope acid (1, 8-dihydroxy naphthalene 3, 6-disulphonic acid) are changed into blues and bracks when a chromium salt is used as the mordant.

Direct Dyes.—These are colouring matters which dye cellulose fibres from a neutral or alkaline solution without the application of a mordant. They dye animal fibres in a similar manner and also from an acid bath. Like the acid dyestuffs, they are sodium salts of sulphonic acids, but although in the case of the acid dyes the free acid is combined with the fibre, with the direct dyes the metal cation is absorbed along with the organic anion. For this reason these dyestuffs are sometimes referred to as salt dyes. Here again the reason for this affinity has never been fully explained. (See *Theoretical*, above.)

The direct dyestuffs are mainly used for the dyeing and printing of cellulose materials (including rayon) and wool. Certain of them when applied to the latter materials are faster than the acid dyestuffs. A few contain mordant fixing groups and can be dyed upon wool with a chromic mordant or fixed upon cotton with a metallic salt. Certain of these dyestuffs are sold in the form of their soluble complex compounds (chelate compounds) for dyeing cotton directly in shades with good resistance to light.

At least 100 direct dyes are of commercial importance, and, as has already been noted, most of them are derived from benzidine, toluidine or diamidine by the diazo reaction. Congo red, benzopurpurine and direct black are the most important dyestuffs of this class. Others are derived by coupling sulphonic acid compounds with HNO_2 or carbonyl derivatives of J acid (2-amino-5-naphthol 7-sulphonic acid). Among these are the benzofast dyes, the rosanilines and the diazo brilliant scarlets. The toluidine and thiazole dyestuffs, already discussed, are the most important direct dyes commercially.

Developed Dyes.—This term is applied to those colouring matters which are formed on the material being dyed, generally by the diazo reaction. Para red, the first dyestuff of this class, the naphthols and the products derived from primuline have already been discussed. They are used primarily for dyeing cloth in solid

shades which will be partly discharged, or over which other colours will be printed in patterns by the discharge process. (See *Azo Compounds*, above.)

Sulphide Dyes.—All dyestuffs made by the process of thionation, previously discussed, belong to this class. The products are insoluble in water, but when acted upon by aqueous sodium sulphide (Na_2S) or sodium sulphhydrate (NaSH) solutions, they become soluble in water and substantive to cellulose fibres. Although the nature of the sulphide dyestuffs is not known exactly, it is believed that their solubility and dyeing properties can be attributed to a chain of sulphur atoms (S-S), in the molecule, which, upon reduction with sodium sulphide, yields metallic mercaptide groups (SNH_2). After the dyestuff has been applied, oxidation reverses the process with the formation of the S-S linkage again, atmospheric oxygen being sufficient to bring this about.

The sulphide dyes are used primarily for dyeing cotton, either in the raw state, as yarn, or in the piece, that is, after the yarn has been woven into cloth. Their fastness properties vary with their chemical constitution, hydron blue and sulphur fast black 2NCl derived, respectively, from carbazole and *p*-hydroxyphenyl β -naphthylamine, being, in this respect, the outstanding dyestuffs of this class. In general, their fastness properties fall between those of the direct and vat dyestuff. The sulphide dyes are rarely printed.

Vat Dyes.—This term is applied to those colouring matters, which, like the sulphide dyes, are insoluble in water, but which upon alkaline reduction, usually by means of caustic soda (NaOH) and sodium hydrosulphite ($\text{Na}_2\text{S}_2\text{O}_4$), a much more powerful reducing agent than sodium sulphide, (Na_2S), pass into solution in the form of the sodium salt of their leuco compounds. Invariably they possess two or more =C=O groupings, which, upon reduction in this manner pass into =C-ONa . Atmospheric oxygen is again sufficient to reverse the reaction, and thus the insoluble dyestuff is precipitated from a "vat" (that is, a solution of the sodium salt of the leuco compound) when the vat is blown with air. The same reaction takes place when cellulose fibres which have been dyed in the vat are exposed to air.

In general, the vat dyestuffs can be divided into two classes, the indigos (including the thionindigos) and the anthraquinones. Many examples of these dyestuffs have already been given. Because of their insolubility in water, they are usually marketed in the form of pastes (that is, finely divided dyestuff particles suspended in water), such pastes varying from 5% to 25% dyestuff solids depending upon the nature of the individual product and the use to which it is to be put. On the other hand, methods have been developed for the manufacture of these dyestuffs in the form of dry powders, which are readily wetted, and which, when stirred into water, result in colloidal suspensions of dyestuff particles.

The vat dyestuffs can be either dyed or printed. In the latter operation, the reducing agent, usually a formaldehyde hydrosulphite complex, and the alkali are included with the dyestuff in the printing gum (e.g., the paste made with a starch of a natural gum) which is used as a vehicle in the printing operation. When the prints thus obtained are subjected to the action of moist steam at $98^\circ\text{--}102^\circ\text{C}$, the dyestuff is vatted and the pattern is fixed.

The vat dyestuffs, too, can be applied to cotton in the raw state, to cotton yarn or to cotton goods in the piece. In World War II a truly tremendous yardage of various ducks and twills was dyed with the vat dyes by the latter method in England and the United States. (See *Anthraquinone Compounds*, above.) Also during World War II methods were developed in the United States whereby these dyestuffs can be applied to wool with satisfactory results, up to that time such a procedure was impossible by the vatting method because of the destructive action of strong alkali upon animal fibres.

However, shortly after the conclusion of World War I, a line of so-called "solubilized vat dyestuffs" made its appearance in world markets. This development was made possible by the fact that comparatively stable compounds can be formed by subjecting the =C-ONa grouping in a leuco vat dyestuff to the action of sulphur trioxide in the presence of a tertiary base such as pyridine. The sodium salts of the sulphuric acid esters ($\text{=C-O-SO}_3\text{Na}$) of the

reduced vat dyestuffs are thus obtained, and these, possessing water solubility, can be used for dyeing silk or wool as well as cellulose fibres. When such dyings are acted upon by an oxidizing agent, the ester is split, with the formation of the original insoluble vat dyestuff having the grouping $-C=O$.

The anthraquinoid vat dyestuffs are the finest synthetic colouring matters known, particularly to the action of bleaching solutions. Yarn dyed with these products can be woven in patterns or stripes into fabrics made of unbleached cotton yarn, and then the whole fabric can be bleached with strong bleaching agents such as hypochlorite without a material change in the shade of the coloured patterns or stripes. Sharper and cleaner results in partly coloured fabrics are obtained in this manner.

As of the conclusion of World War II, no methods had yet been developed whereby the vat dyestuffs could be applied to acetate silk or to other synthetic fibres, with the exception of rayon. As is well known, the latter material is regenerated cellulose, it can therefore be dyed and printed with all classes of dyestuffs that are used for cotton or linen.

Dyes for Synthetic Fibres—With the increased usage of synthetic fibres such as acetate silk (cellulose acetate), and, in the United States especially, nylon and vinylon, the problems of dyestuff chemists multiplied in proportion to the importance of the fibres, since the greater number of dyestuffs used in the colouring of silk, wool or cellulose fibres possess no affinity for these synthetic materials (see *Theoretical*, above). In Germany, on the other hand, *Zeilwolle* (casein fibre) offered no difficulty, for this material possesses dyeing properties similar to those of wool.

In general, it can be said that the dyestuffs which have been developed for acetate silk are useful also in dyeing other synthetic fibres such as nylon and vinylon. The first of these colouring matters were the onamines, which are soluble derivatives of insoluble azo or anthraquinone compounds, and are formed from the latter by the introduction of CH_3SO_2Na groups in the molecule. These groups are split off from the products during the dyeing operation, leaving the insoluble dyestuff absorbed within the fibre. Later, methods were developed for converting various coloured amino anthraquinones into such finely divided condition that the compounds, although insoluble in water in the ordinary sense of the term, could be used for the direct dyeing of these synthetic fibres from soap solutions. Here again the anthraquinone compounds give the fastest dyings, 1-amino-4-hydroxyanthraquinone, a red, and 1, 4, 5, 8-tetraaminoanthraquinone, a blue, being representative dyestuffs of this class. In addition to dyeing fast shades upon the synthetic fibres, these dyes have the further advantage of possessing no affinity for cotton, linen or rayon. They can therefore be employed together with direct dyes for producing two colour effects upon fabrics woven from these fibres together with those of synthetic origin.

Food Dyes—This class of dyes has been developed particularly in the United States, where an agency of the government officially "certifies" as to the purity of factory lots of a selected number of synthetic dyestuffs which are allowed to be used in foods, confections, soft drinks, etc.

The most important of these "permitted" dyestuffs are naphthol yellow S, ponceau 3R, tartrazine, Gunea green and indigotine (indigo disulphonic acid).

Dyes for Rubber and Plastics—Coloured articles made from rubber or synthetic plastics are common in commerce. The colouring of rubber is brought about by the use of pigments (see below) either in the latex from which the rubber articles are formed, or in the rubber itself during the "milling" operation prior to vulcanization. It is therefore necessary in methods of this kind for the pigments to be composed of finely divided particles, which distribute themselves evenly throughout the rubber being coloured.

Plastic articles are likewise coloured with pigments, the colouring matter, in finely divided condition, being incorporated into the raw materials from which the plastic articles are moulded.

Pigments—By a pigment is meant a colouring material that does not dissolve in, or combine with, the substance being coloured. Pigmentation, therefore, is the even distribution of finely

divided coloured particles throughout such a substance.

Many coloured compounds which are closely related to the synthetic dyestuffs have become important pigments in commerce and, in some cases, the pigments are made from the dyestuffs. Thus, the basic dyes such as malachite green, crystal violet, the rhodamines, etc., containing NH_2 or $N(CH_3)_2$ groups, can be rendered insoluble in ordinary vehicles by precipitating them as their phosphotungstic or phosphomolybdic salts. On various water- or oil-insoluble metallic salts of the acid dyes containing carboxyl ($COOH$) or sulphonic (SO_3H) groups can be prepared, the lead, calcium, barium and aluminum compounds being most generally employed.

Such insoluble dyestuff derivatives are termed "lakes," and they are largely used in the paint, paper and printing ink industries.

In some cases, pigment products are manufactured, which, except for the absence of solubilizing groups, could be used as dyestuffs. The most important of these are the hansa yellows derived from benzidine or substituted benzidines and various acetoacetyl derivatives of aryl amines, such as acetoacetanilide or acetoacet-o-toluidide, by the diazo reaction.

Copper phthalocyanine blue and copper phthalocyanine green could also be included in this class.

A number of the water-insoluble vat dyestuffs, both indigoids and anthraquinoids, are useful in commerce as pigments. Thus, in the United States the blue dyestuffs, and anthrone (vat blue RS) and its monochloro derivative (vat blue GCD), are used in substantial quantities in paints and lacquers for automobiles. Here fastness to sunlight and heat is of extreme importance, and these colouring matters will persist for long periods of time without showing the unsightly effect termed "bronzing."

Dyestuff Standardization—In marketing dyestuffs, the manufacturer invariably establishes what in the industry is termed a "standard" for each individual product sold. All subsequent production is brought to conformity in strength and shade with individual standards. In this way the purchaser is assured of uniform dyings or prints, he knows what per cent of dyestuff, based on the weight of the material to be dyed, to use in order to obtain a required shade with a given depth of colour.

The process used to bring dyestuffs, as they are manufactured to such uniformity, termed "standardization," consists, in the case of dyestuffs which are sold as powders, in first grinding the crude product to a fine powder, then agitating the powder in a machine called a "mixer" until a uniform and representative sample can be taken for "dye test."

A weighed amount of the sample and varying weighed amounts of the standard are then dyed on skeins. The crude dyestuff is then judged by these comparative dyings to be, say, 10% or 15% stronger than the standard. An inert material such as dextrose, sugar, common salt or anhydrous sodium sulphate is then added to the crude dyestuff in the mixer, and, after agitating again for uniformity, another sample is taken. The process is then repeated until the strength of the standard is matched. Few dyestuffs are sold at the strengths they possess as they come from the manufacturing processes.

In case of slight variations in shade from the standards, correction is made by adding, to the lot or batch of dyestuff being standardized, small amounts of other dyestuffs of the same class. For example, if a lot of benzopurpurine, a red of the direct dyestuff class, is found to be slightly bluer in shade than the standard, small amounts of an orange direct dyestuff might be added. The expert dyer chooses such "shading" dyestuffs, as they are called, with extreme care, since such blending of two shades leads, many times, to loss of brilliancy in the dyestuffs he is standardizing.

In spite of this fact, a large percentage of dyeing done on textiles, paper, leather, etc., is done with a mixture of dyestuffs. In these cases, of course, only dyes of the same dyeing class can be mixed. This mixing is usually done where the dyestuff is applied. Yet there are many ready mixed brands of dyestuffs in world markets.

The standardization of dyestuffs sold in the form of pastes is

carried out in exactly the same manner as in the case of powders, the wet "filter cakes" as they come from the dye making process being placed in the mixer. Here water or a water soluble liquid such as glycerine or diethyleneglycol, is the diluent rather than materials such as salt or sugar.

Occasionally, these paste dyestuffs, after standardization, are dried down in the form of flakes or pellets.

Many other tests may be applied to dyestuffs before standardization is completed. The rate of solution and the amount of insoluble material present are sometimes determined. Or again the products may be examined for the presence of minute quantities of "germ" which would scratch the soft copper rollers, suitably engraved, from which dyestuffs are printed in patterns.

Thus, the chemical synthesis of dyestuffs is far from being the whole of dyestuff manufacture. Competition in this field has forced those concerns engaged in the business to higher and higher standards of production, particularly as to purity and cleanliness of the dyestuffs marketed.

HISTORICAL

In 1856 W. H. Perkin, a young English chemist, was working as an assistant to the noted German chemist, A. W. Hofmann, who, in 1842, had become the director of the Royal College of Chemistry in London. Both were interested in the chemistry of quinine, and during the Easter vacation while Hofmann was off on a vacation, Perkin attempted to synthesize the substance by oxidizing a mixture of aniline and toluidine with sulphuric acid and sodium dichromate. He did not understand at the time the exact nature of the material which was being oxidized.

It was only natural, therefore, that an unexpected product was obtained from the reaction—a black tar, which on treatment with alcohol gave a purple coloured solution from which silk and wool could be dyed in violet shades.

Perkin called the material mauve and almost immediately set up a small plant at Greenford Green, London, for its manufacture. It was the first synthetic or coal tar dyestuff manufactured commercially. From this accidental discovery and small private venture, the enormous synthetic dyestuff industry of the modern world has developed.

Before many years, other colours were added to the line. Nicholson found the first of the many alkali blues in 1857, and in 1858 Hofmann discovered magenta. These first colours, obtained by the oxidation of various amino compounds, belonged to the classes of dyestuffs recognized later as the azines and triphenylmethanes. The first azo dyestuff, aniline yellow, was discovered in 1859 by P. Gness, who a year earlier had developed the diazo reaction. Safranine T also was first synthesized in 1859, and in 1863 T. Martius made Bismarck brown, these early synthetic dyestuffs are the only ones which survive as really important items in modern usage.

In 1868 the first of the natural dyestuffs of vegetable origin alizarine was synthesized from anthracene by Perkin in England and by H. Caro, Graebe and Liebermann in Germany. The latter group's application to cover the process reached the British patent office on June 25, 1869, and Perkin's was received just one day later. Two wholly independent investigators had arrived almost simultaneously at identical solutions of the problem.

From this time forward certain landmarks stand out in the development of the enormous diversity of synthetic dyestuffs available to mankind in the 20th century.

- 1860 Discovery of couine by Caro
- 1871 Discovery of erythrosine by Caro
- 1879 Discovery of Bismarck brown by Caro
- 1880 The completion of the Bayer synthesis of indigo
- 1884 Discovery of crystal violet by Caro and Reiss and first used for direct dyestuff by Reiss
- 1888 Discovery of the hydroxy l. amine by Bohn and I. Schmidt
- 1891 Discovery of the first sulphonated dyestuff of commercial importance by A. Reiss
- 1897 The development of the sodamide process for the manufacture of synthetic indigo by the Badische company in Germany
- 1901 The discovery of indanthrone and flavanthrone, the first important anthraquinone vat dyestuffs, by Bohn
- 1904 Discovery of violanthrone, another anthraquinone vat dye

- 1906 The first synthesis of thionindigo by Friedlander
- 1920 The discovery of jade green, one of the most important of the anthraquinone vat dyestuffs by W. Davis, J. Thompson and A. Thomas
- 1927 The discovery of copper phthalocyanine by H. de Diesbach and E. von der Weid

The number of dyestuffs synthesized in the many organic chemical laboratories in the world has run into the hundreds of thousands. However, comparatively few of these have reached commercial production and usage, less than 1,000 of importance being commonly in use in the world.

In order for a new dyestuff to be commercially successful, it must possess some outstanding property of fastness, ease of application, etc., or an adaptability to a new material or fibre. It has happened in a number of instances that particular dyestuffs, for which no commercial use could be found when originally synthesized, have become important items for the dyeing of new fibres such as *Zellwolle*, acetate silk or nylon.

Commercial—The business begun by Perkin in England in 1857 spread in time to Germany, Switzerland, France, Italy, the U.S.S.R., the United States and Japan.

Developments in Germany, England and the United States, the three largest producing countries as of the beginning of World War II, will be briefly outlined.

In the years from 1862 to 1873, a half dozen establishments were founded in Germany, primarily to undertake the manufacture of synthetic dyestuffs. Thomas H. Norton, an agent for the United States department of commerce, in his report to that department in 1916, designated them as the "six leading German companies."

- Meister, Lucius and Bruning, founded in 1862
- Bayer and Co., founded in 1862
- Kalle and Co., founded in 1861
- Badische Aniline and Soda Manufacturing Co., founded in 1864
- Cassella and Co., founded in 1870
- Berlin Company for Aniline Manufacture, founded in 1873

In addition to these, Norton also listed the "seven smaller German companies," three of which had been in other chemical manufacturing activities prior to the beginning of the synthetic dye stuff business.

- Carl Jager, founded in 1831
- Griesheim Elektron, founded in 1842
- Wulff, Dahl and Co., founded in 1842
- Weiler-ter-Meer, founded in 1877
- Mühlheim, founded in 1879
- Griesheim Chemical Works, founded in 1881
- Leipzig Aniline Manufacturing Co., founded in 1882

As early as 1904 a merger of chemical manufacturing interests began in Germany, the 13 concerns drawing together into two great groups, the one headed by Badische and Bayer, the other by Meister, Lucius and Bruning, the Cassella Co. and Kalle. In 1916 the two groups drew up a closely knit cartel agreement, allocating production and dividing up markets not only in Europe, but throughout the world, for, at the beginning of World War I, the Germans had come to possess a virtual world-wide monopoly on the manufacture of synthetic organic chemicals.

In 1925-26 the two groups merged into the *Interessen Gemeinschaft Färbendindustrie*, the notorious German I.G., by far the wealthiest and most powerful chemical manufacturing combination in the world at the time.

In spite of the lead taken by the Germans, the manufacture of coal tar dyestuffs became a sizable industry in Great Britain after the establishment of Perkin and Son in 1857. Chief among the manufacturing concerns in that country were Simpson, Maule and Nicholson, established in 1860, to become Brook, Simpson and Spiller in 1869, the latter absorbing Perkin and Son in 1874. Reid, Holliday and Sons, originally established in 1830, which took up the manufacture of dyestuffs in 1860, I. Levinstein, Ltd., founded in 1864, the British Alizarine Co., founded in 1882, Claus and Rée, founded in 1891, with which Brook, Simpson and Spiller later affiliated to become Claus and Co. in 1907, and Morton's Sundour Fabrics, which began dyestuff manufacture in 1914, this branch of the business becoming Scottish Dyes, Ltd.,

in 1918

In 1917 Claus and Co. affiliated with I. Levinstein, and in 1919 this group was joined by British Dyes, Ltd., which had been formed from Read, Holliday and Sons, Ltd., in 1915. The new combination was known as the British Dyestuffs Corporation, Ltd. But in 1927, inasmuch as the group by that time had come to include a wide diversity of chemical manufacturing, its name was changed to Imperial Chemical Industries, Ltd.

This was joined in 1928 by Scottish Dyes, Ltd., and, finally, in 1931 by the British Alkazine Co. Thus by the latter year, the manufacture of synthetic dyestuffs in Great Britain had been gathered under a single directorship, and the group had become a division of Imperial Chemical Industries, Ltd.

Prior to World War I only seven small concerns manufactured synthetic dyestuffs in the United States, the largest one being the Schoellkopf Aniline and Chemical Works of Buffalo, N.Y., founded in 1879. Among the others were the Bayer Company of America, a subsidiary of the Bayer Co., Ger., established primarily to manufacture pharmaceuticals, the W. Beckers Aniline and Chemical Works and the Consolidated Color and Chemical Co.

As of 1914, the average monthly number of wage earners in the entire U.S. synthetic dyestuff industry was only 398, and the value of all production was but \$3,470,000.

During World War I the properties and assets of the Schoellkopf Works, Beckers and certain smaller companies became the foundation of the National Aniline & Chemical Co., Inc., later to become a subsidiary and ultimately the National Aniline Division of the Allied Chemical & Dye Corp. In 1916 E. I. du Pont de Nemours & Co. entered the field. Shortly thereafter the Newport Co. and the Calco Chemical Co. took up the manufacture of dye stuffs. As a result of these ventures during the war, the foundation was laid for the building of a truly great synthetic dyestuff industry in the United States. In 1931 the dyestuff branch of the Newport Co. was taken over by du Pont, and in 1929 the Calco Co. was absorbed by American Cyanamid, to become the Calco division of that company.

When the United States entered World War I, the property and patents of the Bayer Company of America were seized by the alien property custodian. Later these assets were sold, those pertaining to dye-stuffs to the Grasselli Chemical Co., which formed a 100% owned subsidiary, the Grasselli Dyestuffs Corp.

About 1923 a 49% interest in this corporation was sold to the Bayer Co. of Germany. Thus, with the formation of the German I.G. in 1926, this concern acquired, through Bayer, a 49% interest in the Grasselli Dyestuffs Corp. In 1928 the remaining 51% interest was sold to the I.G., which by this time had set up in the United States a selling organization called the General Dyestuffs Corp., the manufacturing end of the business, thus partly acquired, being called the General Aniline Corp.

In 1939 these activities were merged with the Agfa Anasco Co. to become the General Aniline and Film Corp. When the U.S. entered World War II, the assets of this corporation were seized by the alien property custodian and the business was put under U.S. management.

Other smaller manufacturers of synthetic dyestuffs in the United States included the Cincinnati Chemical Works, the American Aniline Co., the Young Aniline Co., the Dow Chemical Co. and the Pharma Chemical Co. National Aniline, General Aniline, American Cyanamid and du Pont were the big four. Thus, up to 1950 there had been no merging of the business in the United States as there was in Germany and in Great Britain.

At the conclusion of World War I, the annual capacity of the world to produce synthetic dyestuffs was about 260,000 tons, an increase of about 66% over that of 1913.

With the return of Germany made dyestuffs to the market, overproduction and severe competition were everywhere experienced, and each of the producing countries adopted measures to protect their home industries.

Italy and France created high import duties. Japan subsidized the industry and instituted a licence system of import controls. Great Britain by a proclamation in 1919 prohibited imports ex-

cept under licence from the board of trade. A test case however, resulted in a judgment that this procedure was illegal, and throughout 1920 there were no restrictions, dyes to the value of £7,500,000 being imported. This severe blow to the British industry was followed shortly by a world-wide slump in trade.

The dyestuffs (Import Regulations) act was passed, becoming operative on Jan. 15, 1921, whereby for a period of ten years the importation of dyestuffs and intermediates was prohibited except under licence from the board of trade. This act was continued by amendments until 1934, when it was rewritten without time limitation, but in 1942 it was suspended for the duration of World War II. At the conclusion of the war the licence system was again imposed.

With the rapid growth of the industry in the United States during the years of World War I, governmental action was taken to protect it. By an act of congress in 1916, duties on imports of dyestuffs were fixed at 15% ad valorem, plus five cents per pound specific duty, the act to run for five years. Later, imports were prohibited altogether except under licence from the war trade board. By the Tariff act of 1922, duties for two years were fixed at 66% ad valorem, plus seven cents per pound specific duty after which the ad valorem duty was to be reduced to 45% while the specific duty was to be continued at seven cents per pound, the ad valorem duty being based upon the selling price in the United States. By the Tariff act of 1930, these duties were continued, with the exception of those on indigo and sulphur black, which were reduced to 20% ad valorem and three cents per pound.

In 1936, by a trade agreement with Switzerland, the duties were reduced to flat 40% ad valorem, applicable to every country except Germany, which continued to pay the duties specified in the act of 1930. In spite of this fact, the greater part of the imports of dyestuffs into the United States from 1936 until the beginning of World War II came from that country.

However, as a result of that war Germany lost its position. In each of the years 1948 and 1949 less than 1,000,000 lb of dyes were imported into the United States, and of these imports, Switzerland accounted for more than 95%.

Table VIII discloses the extent of the world's dyestuff business over a period of about 20 years, and the extent to which after World War I, the virtual monopoly in the industry enjoyed by Germany was broken. The table also indicates the effects of World War II upon world production.

TABLE VIII—World Production of Dyestuffs
(In thousands of pounds)

Country	1914	1917	1920	1950
Germany	165,300	166,500	40,570	64,461
United States	111,431	122,745	139,380	202,211
United Kingdom	55,785	61,065	100,000*	†
Soviet Union	9,800	31,000	†	†
Japan	20,210	52,468	14,414	10,180
France	28,120	21,100	37,275	11,050
Italy	15,384*	27,548*	20,010	18,000
Switzerland	24,300	17,170	25,000	†

*Estimated
† Figures not available

The export of dyestuffs from various countries for the years 1938 and 1950 is given in Table IX, 1950 being the last year for which figures are available.

TABLE IX—Exports of Dyestuffs
(In thousands of pounds)

Country	1938	1950
Germany	66,648	28,051
Switzerland	14,586	21,701
United Kingdom	8,910	7,725
France	9,450	9,074
United States	8,170	24,357
Japan	18,611	3,211
Italy	7,331	2,550

The importance of the various chemical classes of dyestuffs in the United States can be understood from production and sales

TABLE X—US Production and Sale of Various Dyestuffs, 1949

Dyestuffs	Production (in thousand pounds)	Sale		
		Quantity (in thousand pounds)	Value (in thousand dollars)	Value (in millions of dollars)
Azo	1,111	55,111	61,439	1.11
Sulphur or sulphonic	12,111	1,111	1,111	1
Indigo and indigotin	12,111	1,111	1,111	1
Anthraquinone	26,107	1,111	1,111	1
Phthalic anhydride and di-	1,111	1,111	1,111	1
phthalic anhydride	1,111	1,111	1,111	1
Acetic anhydride	1,111	1,111	1,111	1
Starch	2,040	1,111	1,111	1
Peroxy acids	1,111	1,111	1,111	1
Naphthalene	1,111	1,111	1,111	1
Resorcinol	705	1,111	1,111	1
Isosorbide	202	1,111	1,111	1
Acridine	115	1,111	1,111	1
Quinoline	115	1,111	1,111	1
Oxams	1	1,111	1,111	1
All other	0.1	1,111	1,111	1

*Includes earlier sales data.

figures in this country in 1949 (See Table X).

It must be understood, however, that the data are not representative of world consumption, the few eastern countries which take the bulk of total exports using the cheaper dyestuffs for the most part.

The synthetic dyestuff industry can be considered as the parent of the enormous organic chemical industry of the world, the petroleum industry excluded. A close relationship exists between the manufacture of dyestuffs and the manufacture of high explosives, pharmaceuticals, perfume bases, plastics and synthetic fibres. Peric acid can be used as a dyestuff intermediate, a dyestuff itself and a high explosive. Sulfonamide, the first of the sulfa drugs and a close relative of sulphuric acid, was first prepared in Germany as an intermediate in 1908, but no use was found for the compound in the dyestuff industry. Indole, a powerful perfume base, is most readily made from indigo phenol, commonly used in the dyestuff industry, is consumed in enormous quantities in the manufacture of plastics.

DYETSKOYE SELO (Detskoye Selo), a town in north Russia, formerly *Tsarskoye Selo*, 15 m. south of Leningrad in lat. 59° 43' N., long. 30° 24' E., on the Duderhof Hills. Pop. (1926) 19,384.

When Peter the Great took the mouth of the Neva river, a Finnish village, Saarniois, stood on the site now occupied by the town and its Russified name, Sarskaya, was changed into Tsarskoye Selo (The Tsar's Village) when Peter presented it to his wife, Catherine. It was later arranged as a summer abode by the Tsaritsa Elizabeth and Catherine II and was subsequently used as such by the Imperial family. As a court residence, the town was the earliest Russian town to be supplied with the conveniences of modern civilization.

The first Russian railway, built in 1837-38, connected it with Leningrad, and in 1887, it was lighted by electricity, the first town on the European continent to be so lighted. It also has the best system of water supply and sanitation in Russia, and on account of its cleanliness, its good sanitation and dry climate, it is a health resort.

In 1917 the Tsar Nicholas II and his family were imprisoned here from March to August, when they were transferred to Tobolsk. Under the Soviet government the former palaces and villas have been turned into museums, schools, hospitals and sanatoria for children. Dyetskoye Selo means Children's Village

and was given to it because in summer it is practically a children's colony. The cathedral of St. Catherine, built by Thon in 1840 is a miniature copy of that at Constantinople. The former imperial park, now the Dyetskoye Selo park, covers 1,680 acres. In it is the "old palace," built in 1724 by Rastrelli, and gorgeously decorated with mother-of-pearl, marble, amber, lapis lazuli, silver and gold, the gallery of Cameron, adorned with fine statues and entrance gates, numerous pavilions and kiosks, and a bronze statue of the poet Pushkin, who was a scholar at the Lyceum. A second palace, the Alexander, was built by Catherine II 1792-96, and designed by Gwarchen.

The Chinese village, bridge and theatre were designed as a result of the interest in China taken by Catherine II. Behind the north wall of the park is the Fedorovsky Gorodok (Fedor town), built for the Tsar's family 1914-17 by the architect Prestchinsky in old Russian style, and now controlled by the Institute of Agronomy.

The Fedor Cathedral was built by Pokrovsky in 1912 in the Pskov-Novgorod style. For a full description of the town, see "Guide to the Soviet Union" (Moscow, 1925, in English). The town is now named Pushkin.

DYKE see DYKE

DYMOKE, the name of an English family holding the office of king's champion. The functions of the champion were to ride into Westminster Hall at the coronation banquet, and challenge all comers to impugn the king's title. (See CHAMPION.) The earliest record of the ceremony at the coronation of an English king dates from the accession of Richard II. On this occasion the champion was Sir John Dymoke (d. 1381), who held the manor of Scryvelsby, Lincolnshire, in right of his wife Margaret, granddaughter of Joan Ludlow, who was the daughter and co-heiress of Philip Marmion, last Baron Marmion. The Marmions claimed descent from the lords of Fontenay, hereditary champions of the dukes of Normandy, and held the castle of Tamworth, Leicestershire, and the manor of Scryvelsby, Lincolnshire. The right to the championship was disputed with the Dymoke family by Sir Baldwin de Freville, lord of Tamworth, who was descended from an elder daughter of Philip Marmion. The court of claims eventually decided in favour of the owners of Scryvelsby on the ground that Scryvelsby was held in grand serjeanty, that is, that its tenure was dependent on rendering a special service, in this case the championship.

Sir Thomas Dymoke (1428?-1471) joined a Lancastrian rising in 1469, and, with his brother-in-law Richard, Lord Willoughby and Welles, was beheaded in 1471 by order of Edward IV after he had been induced to leave sanctuary on a promise of personal safety. The estates were restored to his son Sir Robert Dymoke (d. 1546), champion at the coronations of Richard III, Henry VII and Henry VIII, who distinguished himself at the siege of Tournai and became treasurer of the kingdom. His descendants acted as champions at successive coronations. Lewis Dymoke (d. 1820) put in an unsuccessful claim before the House of Lords for the barony of Marmion. His nephew, Henry (1801-65) was champion at the coronation of George IV. On that occasion, Henry Dymoke acted as champion in place of his father, the Rev John Dymoke, who was the rector of Scryvelsby. The clergyman considered the office unfitting for a rector. Henry was accompanied by the duke of Wellington and Lord Howard of Effingham, and the ceremony was carried out in great state. Henry Dymoke was created a baronet, he was succeeded by his brother John, rector of Scryvelsby (1804-73), whose son, Henry Lionel, died without issue in 1875, when the baronetcy became extinct. After the coronation of George IV the ceremony was allowed to lapse, but at the coronation of Edward VII H. S. Dymoke bore the standard of England in Westminster Abbey.

See W. Jones, *Crowns and Coronations* (1883).

DYNAMICS. Two groups of bodies are said to be coupled when the influence of each group upon the other is appreciable. There are many kinds of influence and so a general theory of action is complicated. In this article simple cases are considered first, difficult ones later. Dynamics is a theory of the differential equations of coupled systems. The necessary modification of the

equations of free motion may involve the addition of new equations to fully describe the collisions, connections and constraints produced by the coupling. In the formulation and solution of these equations the laws of mechanics (see MECHANICS) play an important part. When two bodies are in contact or are joined in some way, the nature of the coupling is manifest. When there is electromagnetic or gravitational action between them the nature of the coupling is obscure, yet the idea of energy is useful in deriving relations for a set of electrified conductors and in many other cases of invisible coupling. The aim in dynamics is to describe the configuration and motion of an interacting material aggregate by the values and rates of change of a suitably chosen set of co ordinates. These final equations must be derived from prescribed initial values or conditions and a set of equations of motion which in one form of the theory express the rates of change of the co ordinates uniformly in terms of the co ordinates and the time at which these quantities are estimated. The number of co ordinates is generally finite but may be large, as in the dynamical theory of gases. It is often convenient to regard the total set of bodies as divided up into separate dynamical systems coupled together. A system need not be restricted to a conservative one for which the total energy or total mass remains constant.

Force—In the search for equations which will describe observed phenomena, mathematicians have used the idea of force to express the fact that terms in different equations are related. Names such as *mass*, *inertia* and *self induction* have been associated with terms which are also in the equations of motion of a system when it is free, while other names have been associated with terms that describe the different types of forces or couplings between different systems. Frictional and deflecting forces generally differ in character from attractions and repulsions. Surface and body forces describe mathematically a supposed difference between contact action and action at a distance.

Change of Axes—With a change of axes of reference some terms may enter into the equations of motion or may disappear from them. When local axes are used special names are given to forces which are definitely associated with the earth's rotation about its axis. Meteorologists speak, for instance, of the *deflecting force* of the earth's rotation. *Centrifugal force* is the name given to a certain type of term associated with rotation, not necessarily the rotation of the earth. When a body moves and spins at the same time it is advantageous to follow the motion of a set of rectangular axes fixed in the body and to use angles introduced by Leonhard Euler (1761) to specify the relation of these axes to another set regarded as fixed.

The Problem of Several Bodies—The difficulty of the problem of three bodies was realized when Alexis Clairaut made his investigations of 1743–50 on the motion of the moon under the influence of the attractions of the earth and sun, and when the great mathematicians of the 18th century devoted much time to lunar theory and to the perturbed motions of the planets. Efforts to overcome the many difficulties led to development of analytical dynamics, a vast subject which now includes ballistics, celestial mechanics, dynamics of a particle, rigid dynamics and the theory of vibrations.

Theory of Impact—The simplifying assumption of a momentary contact between two bodies and a discontinuous transition from one state of motion to another was used by John Wallis and Christopher Wren in 1668 and by Christiaan Huygens in 1669 to work up mathematically the results of experiments on impact. When laws of motion were formulated by Sir Isaac Newton the equations for this simple case contained only the inertia terms and expressed that each body moved uniformly before and after impact. Supplementary equations for the transition expressed the law of conservation of the total linear momentum and an empirical relation between relative velocities before and after impact involving a physical constant, the coefficient of restitution. An investigation of the complicated processes of contraction and expansion in an actual impact was thus avoided. In the dynamics of gases the simple theory of impact is insufficient and use is made of analysis for the two body problem.

Dynamics of a Particle—In this subject use is made of the

simplifying assumption that one body at least is so small in comparison with one of the others that it may be treated as a mass point or particle. The motion of a projectile under gravity provided one important problem and a second one came when Johannes Kepler announced his three laws of planetary motion early in the 17th century and Newton derived them by solving his equations of motion. The law of areas expressed a principle now known in a general form as the principle of the conservation of angular momentum.

Another great problem was that of the motion of a pendulum, and when Huygens tried to render the motion really isochronous by introducing a constraint, mathematicians studied the constrained motion of a particle under gravity. Surfaces and curves as guides received special attention and Huygens' study of the cycloid as a guide was followed by the occurrence of this curve alone in the solution by Jacques Bernoulli of a problem of isochronism proposed by Gottfried Wilhelm Leibniz.

The curve of swiftest descent sought by Jacques Bernoulli was found by his brother Jean to be also a cycloid. Mathematicians became much interested in minimum problems. A principle of least time was formulated by Pierre de Fermat and a principle of least action was announced by Pierre Maupertuis, elucidated by Euler and Joseph Louis Lagrange and finally included in the more comprehensive method of William Rowan Hamilton.

Theory of Vibrations—A third important simplifying assumption was introduced by Brook Taylor about 1715 when he discussed the vibration of a stretched string by a theory of small oscillations. This gave for the periodic motion a linear differential equation with end conditions which determined the different possible modes of vibration. Jean Bernoulli learned the analysis enthusiastically and started a general theory of small oscillations which was developed by his son Daniel and his compatriot Euler who, with Maupertuis, form a celebrated trio of his pupils. The famous problem of the light string loaded at equal intervals was most useful in illustrating the effects of coupling and the relation between the number of particles and the number of independent modes of vibration. When the string hung from a fixed point and vibrated about a vertical position it was a compound pendulum and its oscillations in the limiting case of many loads became those of a heavy chain. Much attention was given to this problem by Joseph Louis Lagrange in his *Mechanique Analytique* of 1788. Similar analysis has been developed for acoustical, electrical and mechanical filters. The theory of small oscillations is of much importance in the study of vibration dampers for engines and of the torsional oscillation of shafts.

Steady Motion—A fourth simplifying assumption suggested by Newton's work became important in 1748 when Daniel Bernoulli considered the steady motion of a fluid. His relation between velocity, density and pressure along a stream line was much like a statement of the principle of the conservation of energy. Steadily rotating gravitating fluid occurred in the tidal theory of Colin Maclaurin (1742) and in the theory of the earth's figure of Alexis Clairaut (1743). Maclaurin's idea of level surfaces was made more definite by Clairaut's use of a force function V constant on such surfaces and related to the pressure p by equations now known as the fundamental equations of hydrostatics. The rotating system is, in fact, static relative to a set of moving axes.

Rigid Dynamics—Interest in the dynamics of a rotating projectile was aroused by the publication in 1743 of *New Principles of Gunnery* by Benjamin Robbins. The German translation by Euler with comments was translated into French and English.

In 1743, J. le Rond d'Alembert gave in his *Traité Dynamique* a form of the principle of virtual work which now bears his name (see MECHANICS). In the applications each small part of a rigid body is regarded as a dynamical system with its own mass and equations of motion. There is supposedly a cancellation of internal forces when the individual equations of motion are combined so the final equations for the whole body contain only inertia terms and resultants of body and surface forces. The equations of moments, however, involve resultant couples and inertia terms having factors known respectively as moments of inertia about the co ordinate axes and products of inertia about pairs of

co ordinate planes. Principal axes chosen so that the products of inertia vanish are usually suitable moving axes for the specification of the motion of a spinning body. Rates of turn (w, w, w_3) about these axes that will give just the right spin at each moment are connected with the moments (L, M, N) of the driving couple by Euler's equations

$$Aw' - (B - C)w_3 w_1 = L, Bw' - (C - A)w_3 w_2 = M, Cw' - (A - B)w_3 w_1 = N,$$

where A, B, C are the moments of inertia about the principal axes. Suitable extensions of these equations for a body with one point fixed give the motion of an arbitrarily moving rigid body and are most useful in the dynamics of the ship, locomotive, aeroplane and balloon. The influence of a ship's motion on the rate of a watch led in 1765 to the gumbal suspension of a marine chronometer (see CHRONOMETER) and when this mode of suspension was extended to a flywheel in 1810 (see GYROSCOPE) the general equations became still more important. Simeon D. Poisson added to the theory of moving axes in his *Traité de Mécanique* (2 vols., 1811 and 1813) in which he derived Euler's equations and in later work on the deviation of falling bodies and projectiles caused by the rotation of the earth. The full significance of the terms in the equations of motion that are introduced by this rotation was indicated by Gaspard G. de Coriolis in 1835. The motion of a rigid body about a fixed point was represented geometrically by the rolling of an associated ellipsoid in a fixed plane in Louis Poincaré's *Théorie Nouvelle de la Rotation des Corps* of 1834 which was republished in 1851 when Foucault's experiments with the gyroscope created great interest in the subject.

Lagrange's Equations.—In the theory of small oscillations the force function V is regarded as a potential energy which is a minimum and zero in a state of equilibrium specified by zero values of a set of generalized co-ordinates q_1, q_2, \dots, q_n . In a disturbed state V is represented approximately by a positive quadratic form in q_1, q_2, \dots, q_n while the kinetic energy T is expressed as a homogeneous quadratic form in the rates of change $\dot{q}_1, \dot{q}_2, \dots, \dot{q}_n$ of the generalized co-ordinates. Lagrange then found that the equations of motion in the generalized co-ordinates are identical with equations derived by the calculus of variations from a time integral of the quantity $L = T - V$. The equivalence of these variational equations with the usual equations of motion in Cartesian co-ordinates has been proved by actual change of variables for a very general type of dynamical system even though some of the equations of transformation express conditions of constraint. Indeed, in choosing q_1, q_2, \dots, q_n the aim is to satisfy the conditions of constraint automatically. Thus, for a particle constrained to move on a surface

$$r = f(q_1, q_2), \quad y = g(q_1, q_2), \quad z = h(q_1, q_2)$$

the parameters q_1, q_2 may be used as generalized co-ordinates which are two in number instead of three. Since V depends only on r, y and z it is a function of q_1, q_2 while T is a quadratic function of \dot{q}_1, \dot{q}_2 with coefficients depending on q_1 and q_2 . Lagrange's equations are then

$$\left(\frac{d}{dt} \right) \left(\frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = 0, \quad r = 1, 2$$

The particles, and the surface form a coupled system but the surface is treated as so massive that its motion may be neglected.

In general, L is called the kinetic potential and n the number of degrees of freedom of the dynamical system. L sometimes has an important physical significance. Thus in the work of Alfred Clebsch (1859) on variational principles in hydrodynamics L is a pressure integral.

Perturbations and stability.—From 1770-1870 Pierre Simon de Laplace enriched dynamics by work on celestial mechanics, the tides, and the stability of the solar system. Developing earlier work of Clairaut, d'Alembert, Euler and Lagrange on the theory of perturbations, Laplace modified the existing theory of forced oscillations by supposing the free vibrations of the mechanical system to be damped whether they were vibrations about a state of equilibrium or about a state of steady motion. Attention was then fixed on the final periodic state sustained by

the periodic driving force. A resulting dynamical theory of the tides partially justified the older equilibrium theory. The theory of forced oscillations of a system with natural damping is quite important in the theory of structures and in the theory of electric circuits. In acoustics it forms a basis for the theory of resonators and the theory of reverberation.

Laplace considered the possibility of the occurrence of secular terms (with factors linear in the time) in the solution of the dynamical equations for the solar system. Such terms would imply a continued departure from an existing state of motion or instability. He showed that the solution of a linear differential equation with periodic coefficients is not generally periodic. His approximate solution with secular terms was replaced eventually by terms with exponential factors, a result which was generalized in 1883 (*Annales Ecole Normale*, Paris) by Gaston Floquet. Laplace's work on the solar system was continued by George William Hill about 1873 and was applied about 1883 to the problem of maintaining acoustical vibrations by John William Strutt (afterwards Lord Rayleigh). The conditions under which periodic or undamped natural vibrations can occur are now important for the production of sound, radio waves and other useful effects. A knowledge of these conditions is important also in the design of aircraft, locomotives, ships and all kinds of controls.

Stability was much studied when the development of the steam engine emphasized the need of regulation. The centrifugal governor of Huygens for the regulation of clocks, modified for water wheels and windmills, was adapted to the steam engine by James Watt (1788) after his flywheel of 1782 gave insufficient safety. Modifications of the centrifugal governor included springs or frictional devices such as the ring of Joseph von Fraunhofer or the dashpot of Sir George Airy. The theory of Airy (*Mem. Roy. Astron. Soc. London*, 1840) and James Clerk Maxwell (*Trans. Roy. Soc. London*, 1868) for existing governors required conditions that each root of an algebraic equation should have a negative real part. Edward John Routh expressed the conditions in a useful form and in 1877 gained the Adams prize for his *Treatise on the Stability of Motion*. Further important applications of the conditions were visualized in 1893 (*Schweizerische Bauzeitung*), when Aurel Stodola worked on the regulation of water turbines and in 1895 (*Math. Ann.*) when Adolf Hurwitz expressed the necessary and sufficient conditions in determinantal form. The conditions for equations up to the eighth degree occurred in studies of the stability of arc lights, aircraft, locomotives, electrical machines and coupled gyroscopes.

Kinetic stability imposed by gyroscopic forces or oscillations was studied by William Thomson (later Baron Kelvin of Largs) and Percy Guthrie Tait in their *Natural Philosophy*. Later work by Paul Appell (1904), Sir Horace Lamb (*Proc. Roy. Soc. London*, 1908), Andrew Stephenson (*Phil. Mag.*, 1908) and Emile Jougouet (*Comptes Rendus Acad. Sci.*, Paris, 1931) should be mentioned. Jougouet has continued Stodola's work on the secular stability of the rotors of turbines.

An important paper on stability was published by Alexander Liapounoff in 1892 and was translated into French (*Annales*, Univ. Toulouse, 1904). In 1902 he gave applications to the rotating gravitating mass of fluid whose stability was being examined by Henri Poincaré and Sir George Darwin.

Analytical Dynamics.—The powerful analysis developed for dynamics is now a necessary equipment of many research workers in dynamical astronomy, statistical mechanics and chemical physics. One important step was the use by Poisson and others of the notation $\frac{\partial L}{\partial \dot{q}_i}$ for the components of generalized momenta which occur in Lagrange's equations. Poisson added much to the theory of these equations and, like Lagrange, introduced a bracket symbol for a sum of functional determinants. The Poisson bracket (u, v) is formed from any two functions of the set of variables $(q_1, q_2, \dots, q_n, p_1, p_2, \dots, p_n)$ and each determinant is taken with respect to a pair of variables such as (q_r, p_r) having the same index r . Poisson's brackets are useful in the formulation of the necessary and sufficient conditions that a transformation of variables from (p, q) to (P, Q) may be a contact transformation, a type much used in dynamics, optics and the theory of

compressible fluids. In 1809 Poisson found that his bracket expression sometimes derived a new integral of the equations of motion from two known integrals. This theorem played a role in the new dynamics created by William Rowan Hamilton in 1834 when he extended to dynamics his successful use of a characteristic function and a partial differential equation in geometrical optics.

Hamilton's Canonical Equations—For a conservative system Hamilton's canonical function (*Trans. of the Royal Irish Academy, Dublin, 1834-35*)

$$H = \sum p_r q_r' - L$$

is the total energy $T+V$. When in H the quantities q_r' are expressed in terms of the p_r 's and q_r 's by means of the equations defining the p_r 's it is found that with arbitrary variations $\delta p_r, \delta q_r$ of the $2n$ quantities p_r, q_r ,

$$H = \sum (q_r' \delta p_r - p_r' \delta q_r)$$

or

$$q_r' = \partial H / \partial p_r, \quad p_r' = -\partial H / \partial q_r, \quad r = 1, 2, \dots, n$$

These $2n$ equations of the first order may be contrasted with Lagrange's n equations of the second order. While Lagrange's equations may be used to describe the motion of a representative point in a space S_n , Hamilton's canonical equations give the motion of a representative point in a space S_{2n} . This second representation was used successfully in the kinetic theory of gases by Ludwig Boltzmann (1868 & 1871) and in statistical mechanics by Willard Gibbs (1902) who called the integral

$$\int \delta p_1 \delta p_2 \delta p_3 \delta q_1 \delta q_2 \delta q_3$$

the extension in phase, and interpreted a theorem of Joseph Liouville (*Journal de Mathématiques Pures et Appliquées*, 1838) as a conservation of extension in phase for an element of phase space moving with the dust of representative points.

The Hamilton Jacobi Partial Differential Equation—An important feature of Hamilton's dynamics is that the canonical equations are associated with a partial differential equation

$$\partial S / \partial t + H(q_r, \partial S / \partial q_r) = 0$$

in the $n+1$ independent variables q_1, q_2, \dots, q_n, t . The function H on the right depends on q_1, q_2, \dots, q_n and the n partial derivatives of H with respect to these variables. This equation and the associated canonical equations are of great importance in quantum theory, celestial mechanics and statistical mechanics.

There are many ways of solving a partial differential equation of the first order and any method which furnishes a complete integral

$$S = S(q_1, q_2, \dots, q_n, a_1, a_2, \dots, a_n, t)$$

containing n arbitrary constants a_1, a_2, \dots, a_n , can be used with advantage to form equations

$$p_r = \partial S / \partial q_r, \quad b_r = -\partial S / \partial a_r$$

expressing the a 's and b 's in terms of the variables p_r, q_r, t and incidentally providing solutions of the canonical equations. Furthermore, the transformation from the quantities (q_r, p_r) to the quantities (a_r, b_r) is a contact transformation, being characterized by a relation of type

$$\sum b_r da_r = \sum p_r dq_r - H dt - dS$$

Contact transformations play a large part in analytical dynamics and in 1895 Sophus Lie pictured the motion of a dynamical system as a succession of infinitesimal contact transformations. In the theory of perturbations H may be replaced by a new function $H+K$ where K is a "perturbation function". The new variables $(a_r + \int a_r, b_r + \int b_r)$ are then related to K by the equations

$$\int a_r = \partial K / \partial b_r, \quad \int b_r = -\partial K / \partial a_r$$

and vary during the motion if K is not constant. This exhibits the perturbed orbit as the gradual modification of an orbit within the group of orbits appropriate to the unperturbed system. This form of solution is particularly important when K is small in comparison with H .

When a dynamical system is specified by a system of differential equations of type

$$\dot{x}_r = F_r(x_1, x_2, \dots, x_n, t) \quad r = 1, 2, \dots, n$$

as in the work of Hamilton, Liapounoff, Poincaré and George D. Birkhoff, the eventual behaviour for large values of t is needed. Poincaré uses the term "stabilité à la Poisson" for a particular type of stability which has been exemplified by the studies of Jean Chazy, Paris (*Comptes Rendus Acad. Sci., Ann. Ecole Normale*, 1921) on the eventual behaviour in the problem of three bodies. Birkhoff's idea of recurrent system (*Bull. Soc. Math., France*, 1912) is helpful in elucidating this behaviour. In this order of ideas there is an important ergodic theorem which is useful in the kinetic theory of gases. The idea of an adiabatic invariant has also become prominent and its relation to dynamics is well presented in an address by Tullio Levi-Civita (*J. Math. Phys., Mass. Inst. Tech.*, 1934).

The Principle of Safety First—A curve in S_n which Lagrange's differential equations are satisfied may be called a "natural orbit" and compared with a neighbouring curve or orbit for which the differential equations are not satisfied to ascertain if a particle moves so as to avoid blows as far as possible and get minimum action. In Hamilton's principle contemporaneous points are compared, δ denoting a legitimate variation, $\delta \int_{t_0}^{t_1} L dt = 0$.

A form of this principle, much used by Jacobi (1836), produced interest in the deduction of physical equations from variational principles. In electrodynamics, Franz Neumann and Rudolph Clausius were pioneers. In 1864 James Clerk Maxwell used Lagrange's equations to formulate equations of the electromagnetic field. The view was tentatively adopted that a theory based on a general variational principle was dynamical but opinions differed regarding the generality of different proposed principles. The principle of virtual work introduced by Jean Bernoulli and extended by d'Alembert, was used by Lagrange as a foundation for the whole of mechanics. When Carl Friedrich Gauss (1829, 'J. f. d. reine und angewandte Mathematik,' *Werke*, vol. 5) introduced his principle of least constraint, Hamilton, his principle of varying action and Heinrich Hertz, his geometric principle (*Werke*, 1895) there was some choice in the meaning of the word dynamical. Favourite variational principles lost some of their appeal when Routh (1873) pointed out that Lagrange's equations require modification for a rolling motion—that is, for a nonholonomic system, in the terminology of Hertz.

About 1880, however, Jacques and Pierre Curie (*Paris, Comptes Rendus Acad. Sci., Oeuvres*, P. Curie) found that electric charges form on certain compressed crystals, and in 1881 Gabriel Lipmann suggested that dynamically there should be a reciprocal effect in which compression is produced by electric charge. When this was discovered the view prevailed that relations between many physical phenomena may be found by studying the properties of the single function L . Joseph Larmor (*Math. & Phys. Papers*, 1884) proposed least action as fundamental in both dynamics and physics. Joseph John Thomson (1886) applying dynamics to physics and chemistry found many reciprocal relations. Albert Einstein, Erwin Schrödinger, Charles Darwin and many others used least action to justify general equations for new theories of gravitation and quantum mechanics. Yet doubts are felt. The diffusion of heat or matter, the propagation of waves and all dissipative processes introduce difficulties unless a system losing matter or energy is regarded as incomplete. The difficulties regarding non-holonomic motion have been further discussed by Norman Macleod Ferrers (*Quart. J. of Pure and Applied Math.*, 1873), Carl Neumann (*Sächsische Akad. der Wissenschaften Sitzungsberichte*, Leipzig, 1884), George Hamel (*Zeitschrift für Mathematik und Physik*, 1904), Otto Holder (*K. Ges. d. Gottingen Nachrichten Math. Phys. Klasse*, 1896), Paul Appell (1903), Philip Jourdain (*Quart. J. of Pure and Applied Math.*, 1904) and E. Delassus (1913). Ferrers was the first to publish Routh's modification of Lagrange's equations

$$(d/dt)(\partial L / \partial q_r') - \partial L / \partial q_r = \sum A_r A_r$$

where the nonintegrable equations of connection are $\sum A_r q_r' = 0$.

Mixed Equations—Routh also formed a function R resembling L for some freedoms and H for others. If primarily

$$R = L - \sum_{r=1}^n p_r \dot{q}_r$$

and R is later expressed in terms of $p_1, p_2, \dots, p_m, q^{m+1}, q^{m+2}, \dots, q^n$, then

$$R = \sum_{r=1}^m (p_r \dot{q}_r - q_r \dot{p}_r) + \sum_{r=m+1}^n (p_r \dot{q}_r + \dot{p}_r q_r)$$

$$q_r' = -\partial R / \partial p_r, \quad p_r' = \partial R / \partial q_r, \quad r = 1, 2, \dots, m$$

$$p_r = \partial R / \partial q_r', \quad p_r' = \partial R / \partial q_r, \quad r = m+1, m+2, \dots, n$$

The first m equations are Hamiltonian with R in place of H , the others are Lagrangian with R in place of L . "Routh's function" R was used by Routh when L does not involve q_1, q_2, \dots, q_m explicitly but does contain q_1', q_2', \dots, q_m' . Then p_1, p_2, \dots, p_m remain constant during motion and q_1, q_2, \dots, q_m are called ignorable or cyclic co-ordinates. The method is useful for the gyroscope and top. The dynamics of systems with gyroscopic coupling is important in the theory of control.

Dissipative Systems—In 1873 Lord Rayleigh wrote the equation of damped vibration

$$m\ddot{q} + k\dot{q} + sq = f(t)$$

in the generalized Lagrangian form

$$\delta p / dt - dL / dq + \delta F / \delta q' = f(t)$$

where

$$T - V = L = \frac{1}{2} m (\dot{q})^2 - \frac{1}{2} sq^2, \quad p = \partial L / \partial \dot{q}, \quad F = \frac{1}{2} k (\dot{q})^2$$

and called F the dissipation function. The idea was extended to n variables q_1, q_2, \dots, q_n and to functions T, V, E expressible as quadratic forms homogeneous in q_r', q_r, q_r respectively. Terms implying mass coupling, frictional coupling and spring coupling then appeared in the equations of motion as in the general equations for a system of electric circuits.

Various couplings, particularly those of frictional type, have been much studied, particularly in Germany, the United States and England on account of applications to scientific instruments and the stabilization of ships and aeroplanes.

The question whether dissipative dynamical systems can be derived from variational principles of the favourite type has been disputed. Principles which give additional equations are easily found by using multiplied forms of the desired equations added together under the integral sign. Thus the foregoing equation for q and the additional equation

$$m\ddot{Q} - kQ' + sQ = 0$$

may be derived from the principle

$$\delta \int_{t_0}^{t_1} Q [m\ddot{q} + k\dot{q} + sq - f(t)] dt = 0$$

$Q = ge^{kt}$ is a solution of the additional equation when q satisfies $m\ddot{q} + k\dot{q} + sq = 0$ and in this case insertion of the value of Q in the principle permits a reduction to the form

$$\delta \int_{t_0}^{t_1} [s\dot{q}^2 - m(\dot{q}')^2] e^{kt} dt = 0$$

Bodies of Variable Mass—Of interest now for rockets, this subject was treated extensively in 1897 (*Fortschritte d. Math.*) by J. Meschtschersky who refers to earlier work by Arthur Cayley, Hugo Gylden and Hugo von Seeliger. Variation of mass of a balloon in flight, owing to loss of ballast, was an early problem of practical importance, others occurred in astronomy. R. Lehmann-Filhes (1898) considered a type of motion in which the central attracting mass varies slowly in proportion to the time. The orbit was a shrinking ellipse of constant eccentricity. Poincaré found similar results for a planet of slowly varying mass. More general results were obtained by Carlo Maderni (Acad. Lincei, Rome, 1921) and by Edgar Odell Lovett (*ibid.*, 1922) and Giuseppe Armellini (*ibid.*, 1922) the latter being interested chiefly in a planet gaining mass by accretion. H. Vogt (1925) directed attention to the problem of the binary star, whose youthful members lose energy fast by radiation, as observations seemed to indicate that the relative orbit of such a pair is less in size and eccentricity than the corresponding orbit for older stars of similar masses. Thus hard problem induced Armellini to investi-

gate special cases and Levi Civita indicated the relation of the problem of variable mass to the theory of adiabatic invariants.

DYNAMISM (Gr. *dynamis*, power), is the name coined by A. Van Gennep for that attitude of the primitive mind towards the sacred or occult which involves a prevailing sense of its peculiar power or *mana*. He is careful not to impute to the savage a theology in which any clear distinction is drawn between the impersonal and the personal aspects of the divine—as contrasted with advanced religion, which, as may be seen in Buddhism and Christianity respectively, may emphasize the one aspect almost to the exclusion of the other—but suggests dynamism as a term that may be used for classifying any phase of primitive religion in which *mana*, rather than soul or moral personality, receives emphasis as the leading attribute of that which is worshipped.

DYNAMITE, a high explosive consisting essentially of nitroglycerine absorbed in an inert solid material in order to reduce its sensitivity to shock. The most frequently used absorbent is kieselguhr (an infusorial earth), and an average composition is nitroglycerine 75%, kieselguhr 25%. Gelatine dynamite consists of nitroglycerine 75%, nitrocellulose 6%, potassium nitrate 16%, and small quantities of wood meal and chalk. (See EXPLOSIVES)

DYNAMO-ELECTRIC MACHINES see ELECTRIC GENERATOR, MOTOR, ELECTRIC, and ELECTRICAL ARTICLES

DYNAMOMETER, an instrument for measuring force exerted by men, animals and machines (*Gr* *dynamus*, strength, and *meteron*, a measure). The name has been applied generally to all kinds of instruments used in the measurement of a force, as for example electric dynamometers, but the term specially denotes apparatus used in connection with the measurement of work, or in the measurement of the horsepower of engines and motors. If P represent the average value of the component of a force in the direction of the displacement, s , of its point of application, the product Ps measures the work done during the displacement. When the force acts on a body free to turn about a fixed axis only, it is convenient to express the work done by the trans formed product $T\theta$, where T is the average turning moment or torque acting to produce the displacement θ radians. The apparatus used to measure P or T is the dynamometer. The factors s or θ are observed independently. Apparatus is added to some dynamometers by means of which a curve showing the variations of P on a distance base is drawn automatically, the area of the diagram representing the work done, with others, integrating apparatus is combined, from which the work done during a given interval may be read off directly. It is convenient to distinguish between absorption and transmission dynamometers. In the first kind the work done is converted into heat, in the second it is transmitted, after measurement, for use.

Absorption Dynamometers—Baron Prony's dynamometer (*Ann Chim Phys* 1821, vol 19), which has been modified in various ways, consists in its original form of two symmetrically shaped timber beams clamped to the engine shaft. When these are held from turning, their frictional resistance may be adjusted by means of nuts on the screwed bolts which hold them together until the shaft revolves at a given speed. To promote smoothness of action, the rubbing surfaces are lubricated. A weight is moved along the arm of one of the beams until it just keeps the brake steady midway between the stops which must be provided to hold it when the weight fails to do so. The general theory of this kind of brake is as follows—Let F be the whole frictional resistance, r the common radius of the rubbing surfaces, W the force which holds the brake from turning and whose line of action is at a perpendicular distance R from the axis of the shaft, N the revolutions of the shaft per minute, ω its angular velocity in radians per second, then, assuming that the adjustments are made so that the engine runs steadily at a uniform speed, and that the brake is held still, clear of the stops and without oscillation, by W , the torque T exerted by the engine is equal to the frictional torque Fr acting at the brake surfaces, and this is measured by the statical moment of the weight W about the axis of revolution, that is—

$$T = Fr = WR \quad (1)$$

Hence WR measures the torque T .

If more than once force be applied to hold the brake from turning, Fr and therefore T , are measured by the algebraical sum of their individual moments with respect to the axis. If the brake is not balanced, its moment about the axis must be included. Therefore, quite generally,

$$T = \Sigma WR \quad (2)$$

The factor θ of the product $T\theta$ is found by means of a revolution counter. The power of a motor is measured by the rate at which it works, and this is expressed by $T\omega = \frac{T \times 2\pi N}{60}$ in foot-pounds

per second, or $\frac{T \times 2\pi N}{33,000}$ in horsepower units. The latter is commonly referred to as the "brake horsepower." The maintenance of the conditions of steadiness implied in equation (1) depends upon the constancy of F , and therefore of the coefficient of friction μ between the rubbing surfaces. The heating at the surfaces, the variations in their smoothness, and the variations of the lubrication make μ continuously variable, and necessitate frequent adjustment of W or of the nuts. J. V. Poncelet (1788–1867) invented a form of Prony brake which automatically adjusted its grip as μ changed, thereby maintaining F constant

The principle of the compensating brake devised by J. G. Appold (1800–1865) is shown in fig. 1. A flexible steel band lined with wood blocks, is gripped on the motor flywheel or pulley by a screw A , which, together with W' , is adjusted to hold the brake steady. Compensation is effected by the lever L inserted at B . This has a slotted end, engaged by a pin P fixed to the framing, and it will be seen that its action is to slacken the band if the load

FIG 1—APPOLD COMPENSATING BRAKE FIG 2—KELVIN ROPE BRAKE
FIG 3—THOMSON SELF ADJUSTING BRAKE

tends to rise and to tighten it in the contrary case. The external forces holding the brake from turning are W , distant R from the axis, and the reaction, W' , say, of the lever against the fixed pin P , distant R from the axis. The moment of W' may be positive or negative. The torque T at any instant of steady running is therefore $\{WR \pm W'R\}$.

Lord Kelvin patented a brake in 1858 (fig. 2) consisting of a rope or cord wrapped round the circumference of a rotating wheel, to one end of which is applied a regulated force, the other end being fixed to a spring balance. The ropes are spaced laterally by the blocks B, B, B , which also serve to prevent them from slipping sideways. When the wheel is turning in the direction indicated, the forces holding the band are still W , and P , the observed pull on the spring balance. Both these forces usually act at the same radius R , the distance from the axis to the centre line of the rope, in which case the torque T is $(W - P)R$, and consequently the brake horsepower is $\frac{(W - P)R \times 2\pi N}{33,000}$. When μ

changes the weight W rises or falls against the action of the spring balance until a stable condition of running is obtained. The ratio $\frac{W}{P}$ is given by $e^{\mu\theta}$, where $e = 2.718$, μ is the coefficient of friction and θ the angle, measured in radians, subtended by the arc of contact between the rope and the wheel. In fig. 2, $\theta = 2\pi$. The ratio W/P increases very rapidly as θ is increased, and therefore, by making θ sufficiently large, P may conveniently be made a

small fraction of W , thereby rendering errors of observation of the spring balance negligible. Thus this kind of brake though cheap to make is when θ is large enough an exceedingly accurate measuring instrument, readily applied and easily controlled.

It is sometimes necessary to use water to keep the brake wheel cool. Engines specially designed for testing are usually provided with a brake wheel having a trough-shaped rim. Water trickles continuously into the trough and the centrifugal action holds it as in inside lining against the rim where it slowly evaporates.

Fig. 3 shows a band brake invented by James Thomson, suitable for testing motors exerting a constant torque (see *Eng. News*, Oct. 2, 1880). To maintain μ constant, compensation for variation of μ is made by inversely varying θ . A and B are fast and loose pulleys, and the brake band is placed partly over the one and partly over the other. Weights W and w are adjusted to the torque. The band turns with the fast pulley if μ increases, thereby slightly turning the loose pulley, otherwise at rest until θ is adjusted to the new value of μ . This form of brake was also invented independently by J. A. M. L. Carpentier, and the principle has been used in the Ruffard brake. A self-compensating brake of another kind was proposed by Marcel Deprez, as described with Carpentier's in 1880 (*Bulletin de la société d'encouragement Paris*). W. E. Ayerton and J. Perry used a band or rope brake in which compensation is effected by the pulley drawing in or letting out a part of the band or rope which has been roughened or in which a knot has been tied.

In an effective water brake invented by W. Froude (see *Proc. Inst. M. E.*, 1877), two similar castings A and B , each consisting of a boss and circumferential annular channel, are placed face to face on a shaft to which B is keyed, A being free (fig. 4). A ring tube of elliptical section is thus formed. Each channel is divided into a series of pockets by equally spaced vanes inclined at 45° . When A is held still, and B rotated, centrifugal action sets up vortex currents in the water in the pockets, thus a continuous circulation is caused between B and A , and the consequent changes of momentum give rise to oblique reactions. The moments of the components of these actions and reactions in a plane to which the axis of rotation is at right angles are the two aspects of the torque acting, and therefore the torque acting on B through the shaft is

measured by the torque required to hold A still. Froude constructed a brake to take up 1,000 h.p. at 90 r.p.m. by duplicating this apparatus. This replaced the propeller of the ship whose engines were to be tested and the outer casing was held from turning by a suitable arrangement of levers carried to weighing apparatus conveniently disposed on the wharf. The torque corresponding to 2,000 h.p. at 90 r.p.m. is 116,772 foot pounds, and a brake 5 ft. in diameter gave this resistance. Thin metal sluices were arranged to slide between the wheel and casing, and by their means the range of action could be varied from 300 h.p. at 120 r.p.m. to the maximum. The form of the Froude brake developed by Hearn and Froude is widely used. It is especially convenient for measuring the torque of high speed engines.

Osborne Reynolds in 1887 patented a water brake (see *Proc. Inst. C. E.*, 99, p. 167), using a round or turbine to obtain the highly resisting spiral vortices, and arranging passages in the casing for the entry of water at the hub of the wheel and its exit at the circumference. Water enters at E (fig. 5) and finds its way into the interior of the wheel, A , driving the air in front of it through the air passages K, K . Then following into the pocketed chambers V_1, V_2 , it is caught into the vortex, and finally escapes at the circumference, flowing away at F . The airways k, k , in the fixed vanes establish communication between the cores of the vortices and the atmosphere. From $\frac{1}{4}$ to 30 h.p. may be measured at 100 r.p.m. by a brake wheel of this kind 18 in. in diameter. For other speeds the power varies as the cube of the speed.

The casing is held from turning by weights hanging on an attached arm. The cocks regulating the water are connected to the casing so that any tilting automatically regulates the flow, and therefore the thickness of the film in the vortex. In this way the brake may be arranged to maintain a constant torque, notwithstanding variation of the speed. In G. I. Alden's brake (see *Trans. Amer. Soc. Eng.*, vol. 11) the resistance is obtained by turning a cast iron disk against the frictional resistance of two thin copper plates, which are held in a casing free to turn upon the shaft, and are so arranged that the pressure between the rubbing surfaces is controlled, and the heat developed by friction carried away, by the regulated flow of water through the casing. The torque required to hold the casing still against the action of the disk

FIG. 4.—DIAGRAMMATIC ILLUSTRATION OF THE HYDRAULIC BRAKE. FIG. 5.—FROUDE REYNOLDS HYDRAULIC BRAKE.

measures the torque exerted by the shaft to which the disk is keyed.

Transmission Dynamometers.—The essential part of many transmission dynamometers is a spring whose deformation directly measures the magnitude of the force transmitted through it. For many kinds of spring the change of form is practically proportional to the force, but the relation should always be determined experimentally. Gen A J Morn (see *Notice sur divers appareils dynamométriques*, Paris, 1841), in his classical experiments on traction, arranged his apparatus so that the change in form of the spring was continuously recorded on a sheet of paper drawn under a style. For longer experiments he used a "Compteur" or mechanical integrator, suggested by J V Poncelet, from which the work done during a given displacement could be read off directly. This device consists of a roller of radius r , pressed into contact with a disk. The two are carried on a common frame, so arranged that a change in form of the spring causes a relative displacement of the disk and roller, the point of contact moving radially from or towards the centre of the disk. The radial distance x is at any instant proportional to the force acting through the spring. The angular displacement, θ , of the disk is made proportional to the displacement, x , of the point of application of the force by suitable driving gear. If $d\phi$ is the angular displacement of the roller corresponding to displacements, $d\theta$ of the disk, and ds of the point of application of P , a , and C constants, then $d\phi = \frac{x d\theta}{r} = \frac{a}{r} P ds = C P ds$, and therefore

$$\phi = C \int_{s_1}^{s_2} P ds, \text{ that is, the angular displacement of the roller}$$

measures the work done during the displacement from s_1 to s_2 . The shaft carrying the roller is connected to a counter so that ϕ may be observed. The angular velocity of the shaft is proportional to the rate of working. Morn's dynamometer is shown in fig. 6. The transmitting spring is made up of two flat bars linked at their ends. Their centres s_1, s_2 , are held respectively by the pieces A, B, which together form a sliding pair. The block A carries the disk D, B carries the roller R and counting gear. The pulley E is driven from an axle of the carriage. The dynamometer car used by railway engineers to measure the tractive resistance of trains is essentially a development of the Morn apparatus. The pull exerted by the engine on the train passes through a spring. The deflection of the spring is carried through a mechanism to a pencil working on a drum driven continuously from the axle of the car itself. The curve drawn by the pencil then shows the tractive force in terms of the distance. A second pencil electrically connected to a clock traces a time line on the diagram, with a kick at definite intervals of time. A third pencil traces an observation line in which a kick can be made at will by pressing any one of the electrical pushes placed about the car, and a fourth draws a datum line. Other lines are also traced recording events of interest. The spring of the dynamometer car is usually made up of flat plates, spaced by distance pieces nibbed into the plates at the centre and by rollers at the ends. The draw bar is connected to the buckle, which is carried on rollers, the ends of the spring resting on plates fixed to the under frame. The gear operating the paper roll is driven from the axle of an independent wheel which is let down into contact with the rail when required. This wheel serves also to measure the distance travelled. A Morn disk and roller integrator is usually connected with the apparatus, so that the work done during a journey may be read off. A detailed account of a railway dynamometer car will be found in the *Railway Engineer*, Dec 1923.

FIG. 6—TRACTION DYNAMOMETER

In spring dynamometers designed to measure a transmitted torque, the mechanical problem of ascertaining the change of form of the spring is complicated by the fact that the spring and the whole apparatus are rotating together. In the Ayrton and Perry transmission dynamometer or spring coupling of this type, the relative

angular displacement is proportional to the radius of the circle described by the end of a light lever operated by mechanism from the spring connected parts. By a device used by W E Dalby (*Proc Inst C E*, 1897-98, p 132) the change in form of the spring is shown on a fixed indicator, which may be placed in any convenient position. Two equal sprocket wheels, Q_1, Q_2 , are fastened, the one to the spring pulley, the other to the shaft. An endless band is placed over them to form two loops, which during rotation remain at the same distance apart, unless relative angular displacement occurs between Q_1 and Q_2 (fig. 7) as a result of a change in form of the spring. The change in the distance d is proportional to the change in the torque transmitted from the shaft to the pulley. To measure this, guide pulleys are placed in the loops guided by a geometric slide, the one pulley carrying a scale, and the other an index. A recording drum or integrating apparatus may be arranged on the pulley frames.

Every part of a machine transmitting force suffers elastic deformation, and the force may be measured indirectly by measuring the deformation. The relation between the two should in all cases be found experimentally. G A Hirn (see *Les Pendynamomètres*, Paris, 1876) employed this principle to measure the torque transmitted by a shaft. Signor Rosso used a telephonic method to effect the same end, and mechanical, optical and telephonic devices have

FIG. 7—DALBY TRANSMISSION DYNAMOMETER

been utilized by the Rev F J Jervis-Smith (See *Phil Mag*, Feb 1898). H Frahm (*Zeitschrift des Vereins deutscher Ingenieure*, May 31, 1902), during an important investigation on the torsional vibration of propeller shafts, measured the relative angular displacement of two flanges on a propeller shaft, selected as far apart as possible, by means of an electrical device (*Engineering*, Feb 6, 1903). These measurements were utilized in combination with appropriate elastic coefficients of the material to find the horsepower transmitted from the engines along the shaft to the propeller. In this way the effective horsepower and also the mechanical efficiency of a number of large marine engines, each of several thousand horsepower, have been determined. The method of deducing the power transmitted from observations based on the elastic deformation of the parts is specially useful in turbine driven engines because the steam engine indicator from which the indicated horsepower is calculated cannot be used with a turbine.

In the Thring-Hopkinson torsion meter, the twist between points on a short length of the propeller is observed. A cylindrical sleeve is gripped to the shaft at one end and is free from the shaft at the other end so that there is relative motion of twist between the free end of the sleeve and the shaft. This relative motion is utilized to give angular displacement to a mirror which reflects light from a fixed source to a fixed scale and flashes an image to the scale once per revolution. At moderate speeds the intermittent images appear continuous to the eye and so a continuous indication is given on the scale of the relative twist of the ends of a length of shaft equal in length to the sleeve. As the torque increases the twist increases and the angular displacement of the mirror increases and the indication on the scale shows the instantaneous amount of twist. From the twist the torque on the shaft can be calculated.

FIG. 8—TRANSMISSION DYNAMOMETER

In the Moullin torsion meter the relative twist of a defined length of the shaft is made to alter the self-induction of a coil mounted upon and rotating with the shaft. An alternating current is supplied to the coil through brushes and slip rings, and the variation of this current depends upon the variation of the self-in-

duction of the coil so that current variation is thereby related to twist of shaft. Meters placed in series with the coil are calibrated to read torque directly. A description of this instrument will be found in the first report of the Marine Oil Engine Trials committee together with some records taken on the shaft of the "Svaymore" when under trial. In the Ford torsion meter the relative twist of a definite length of shaft alters the in-grip on a transducer mounted on the shaft with the result that there is a variation of the e.m.f. of the secondary circuit. This variation is related to the twist and therefore to the torque on the shaft.

The difference in the tensions in the driving and slack sides of a driving belt has been the basis of transmission dynamometers. For examples, reference may be made to the W. Froude belt dynamometer (*Proc Inst M E*, 1858) and to the Hefner Altneel dynamometer (see *Electrotechnischen Zeitschrift*, 1881, 7).

When a shaft is driven by means of gearing the driving torque is measured by the product of the resultant pressure P acting between the wheel teeth and the radius of the pitch circle of the wheel fixed to the shaft. Fig. 8, which has been reproduced from

FIG. 8—ELECTRIC CRADLE DYNAMOMETER

J. White's *New Century of Inventions* (Manchester 1822) illustrates possibly the earliest application of this principle to dynamometry. The wheel D keyed to the shaft overcoming the resistance to be measured, is driven from wheel N by two bevel wheels L and K , carried in a loose pulley B . The two shafts though in a line, are independent. A torque applied to the shaft A can be transmitted to D , neglecting friction, without change only if the central pulley K is held from turning, the torque required to do this is twice the torque transmitted.

The torque acting on the armature of an electric motor is necessarily accompanied by an equal and opposite torque acting on the frame. If, therefore, the motor frame is mounted so that it is free to turn, and it is prevented from turning by the application of a torque, this applied torque T , measures the armature torque.

The rate at which the motor is transmitting work is then—
$$\frac{T \pi n}{550}$$

H.P., where n is the revolutions per second of the armature.

Electric dynamometers based on this principle are widely used to measure the power of high-speed engines. Fig. 9 is an illustration of the electric dynamometer coupled to the Ricardo experimental gasoline engine. The engine shaft is coupled to the armature of the dynamo. The dynamo frame is held in ball bearings only and is thus free to turn about the axis of the armature shaft. Attached to the dynamo frame are light arms. The arm to the left carries a scale pan W and is hooked to a spring balance suspended from a fixed support F and adjustable in position vertically by the hand wheel H . The arm to the right is connected to the piston of a dash pot P by the vertical rod R . Small oscillations are controlled by the dash pot. When the engine is running under load, weights are added to W and the hand wheel H is adjusted to keep the pointer end of the arm at the centre of the scale on the fixed support. The load, derived from W and the spring balance reading multiplied by the perpendicular distance of its line of action from the axis of revolution, measures the reaction T against which the armature is turned. A method designed by F. W. Lancaster to test the efficiency of worm gears may be closed in a dynamometer since frictional loss in a worm and wheel is measured directly by weigh-

ing the reaction the friction produces. A description of this interesting scheme, set up in the National Physical Laboratory will be found in Appendix Q of a paper entitled "Worm Gear," read before the Institution of Automobile Engineers, Proceedings session 1912-13.

DYNAMOTOR, an electrical machine which when set in motion by mechanical means generates electricity, and which without any alteration, is capable of doing mechanical work when supplied with an electric current. Its action is thus reversible (See **ELECTRIC GENERATOR AND MOTOR**, **ELECTRIC**).

DYNAPHONE, one of the latest additions to the resources of the modern orchestral composer. Described, not too enlighteningly, as "an apparatus for the emission of sound waves" it has been utilized by the French composer, Arthur Honegger, in a ballet entitled *Rose et mal*.

DYNASTY, a family or line of rulers, a succession of sovereigns of a country belonging to a single family or tracing their descent to a common ancestor (Gr. *dynastia*, sovereignty). The term is particularly used in the history of ancient Egypt as a convenient means of arranging the chronology.

DYNE, the unit of force in the centimetre gram second system. It is the force which, acting on one gram of mass, produces an acceleration of one centimetre per second per second. It is $1/1000$ the gravitational unit of force which is the weight of one gram of mass, g being the acceleration due to gravity (See **GRAM** [**GRAMME**], **MECHANICS**, **PHYSICAL UNITS**).

DYOTT, THOMAS W. (1771-1861), U.S. glass manufacturer was born in England. Nothing is known of his early life until his arrival in the United States toward the end of the 18th century. He soon established himself in Philadelphia, where he set himself up in what became an immensely successful shoe shining enterprise, the first of its kind in the city. It is not known exactly when he entered the patent medicine business, but in that field, too, the enterprising Dyott was soon successful. His medicines, with which he claimed to be able to cure all human ailments, were used throughout the entire United States. About 1812 he took, with no authority but his own title of doctor of medicine. Dyott soon began to advertise the sale of bottles, as well as medicines, and about 1818 he became the agent for a number of glass manufacturers. There is some dispute about the year in which he first began to manufacture glass himself, the date sometimes being put as early as 1822, but in any case he probably did not purchase the Philadelphia and Kensington Glass Works until 1833. He enlarged and improved the plant and was soon manufacturing bottles of every description, introducing a number of designs which were later copied extensively and still later became collectors' items. Dyott's downfall was caused by the failure of the bank he had established as a part of his model community, Dyottville, or, as it was sometimes called, Temperanceville, because Dyott would not hire any worker until he had taken a temperance pledge. When the bank failed in the late 1830s, Dyott was proclaimed a "fraudulent bankrupt" and the Kensington works fell into other hands while Dyott served a prison sentence. He died in 1861.

DYRRACHIUM, CAMPAIGN OF (48 B.C.) Having destroyed Pompey's power in Spain, Julius Caesar returned to Italy, and on Nov. 23, 49 B.C. set sail from Brundisium with seven legions for Paestum on the Elyric coast. Landing on Nov. 29, on Dec. 2 he headed for Dyrrachium which, however, he failed to capture. Though numerically weaker than Pompey he succeeded in cutting him off from this city, and then to strengthen his convoys he drew a circle of trenches about 16 mi. in length round Pompey's army. Two deserters from Caesar's camp informed Pompey of the weak-

position in his defenses, and acting on this information Pompey determined to attack his enemy's left flank, which rested on the coast. Caesar had built round Pompey's right flank a line of contravallation and one of circumvallation, between which was posted the ninth legion. Pompey's attack was made at dawn. He huddled a number of archers and slingers in rear of Caesar's men, and while these broke into the unfinished works he attacked them in front with 60 cohorts. The ninth legion, taken in front, flank and rear, broke in confusion and spread panic among the reinforcements which had been sent out by Marcellinus, near whose camp Antony checked the Pompeians by a bold counterattack. Caesar hearing of the disaster, moved rapidly with such cohorts as he could collect toward the scene of action, only to find that Pompey had established a new camp on his own original left flank. Nothing daunted, Caesar entrenched his men opposite to Pompey, and attempted to turn Pompey's left flank, but the attack failed. In this battle Caesar suffered a severe defeat, and not only were his losses considerable, but his loss of prestige was almost disastrous to his cause. Caesar's operations throughout this campaign, though daring in the extreme, were essentially faulty. By attempting to enclose a numerically superior adversary he was strong nowhere, and had Pompey known how to win victory as well as fight a battle Caesar must have been decisively defeated (See PHARSALUS, BATTLE OF).

DYSART see KIRKCALDY

DYSENTERY The term dysentery, the bloody flux of former times, denotes a symptom complex, the passage of blood and mucus in the stools, together with abdominal pain and straining. This combination is not confined to one distinct disease, is common to a number of conditions with ulceration and inflammation of the large intestine and is therefore determined by a variety of different microbial agents.

Types of Dysentery—Dysentery may be classified as follows.

Bacillary or Epidemic Dysentery, for which the following organisms are responsible. (1) Shiga's bacillus (*Shigella shigae*) causes the acute acute and fatal form in most tropical countries. (2) Schmutz's bacillus (*Shigella schmutzi*) closely resembles the former in its biochemical reactions and in many other respects. It produces usually a less serious clinical manifestation and accounted for 12% of cases during World War II. (3) Flexner's bacillus (*Shigella flexneri*) is a species divisible into several subtypes. It is common in temperate countries, as well as in the tropics, and produces a clinical disease of average severity. (4) Sonne's bacillus (*Shigella sonnei*) is common all over the world, especially in temperate countries, and spreads with great rapidity causing epidemics in infants and children, though it may produce severe dysentery in adults. It differs from all other dysentery bacilli in fermenting lactose, but produces its own specific antigens and agglutinins in the body.

Protozoal or Endemic Dysenteries—(1) Amoebiasis, or infection with the dysentery amoeba (*Entamoeba histolytica* [Entamoeba] *histolytica*, F. R. Schaudinn, 1903), includes (a) primary intestinal amoebiasis or amoebic dysentery and (b) secondary amoebiasis—hepatic amoebiasis—or amoebic abscess of the liver, lung, brain or spleen, sometimes also amoebic extraintestinal ulcers (of buttocks or perineum) and amoebic invasion of the skin. (2) Balantidiasis, or infection of the intestinal canal with an infusorian, *Balantidium coli*. The course and pathology of this disease resembles amoebic dysentery. This infection is rare in man, but common in animals, especially pigs and larger apes. (3) Coccidiosis, an infection with *Isospora hominis*, a rare disease of the intestinal tract of man. (4) Giardiasis (or lambliaosis), an infection of the small intestine with *Gardia intestinalis*, a protozoan flagellate, common in children and producing a mucoid diarrhoea. (5) Malarial dysentery, the passage of blood and mucus in the course of infection with the malarial parasite (*Plasmodium falciparum*), which congregates in the capillaries of the intestinal walls. (6) Leishmanial dysentery, an infection of the intestinal canal with the parasite of kala azar (*Leishmania donovani*), when these organisms are found in the pathological exudate in the faeces.

The Helminthic Dysenteries—A dysenteric syndrome is evoked by ulceration and inflammation, and subsequently by the forma-

tion of adenopapillomata in the intestinal tract by deposition of the eggs of certain trematode worms (or flukes) of the *Bilharzia* genus, which are those known as the bilharzial dysenteries. Of these the most important is *Bilharzia* (or *Schistosoma*) *mansoni* in Africa and South America. Two other species *B. haematobia* and *B. japonica*, may occasionally give rise to similar phenomena. Some other trematodes may evoke dysenteriform symptoms of a minor degree, such as the small fluke *Heterophyes heterophycus* (in Egypt), and those which inhabit the intestinal tract, and a much larger species *Fasciolopsis buski* (in China). Of the nematodes the most striking example is *Oxyphostomum apestomum*, which is commonly found in monkeys, but rarely in man, in Southern Nigeria and central Africa and on the Amazon river in Brazil. These worms, encyst in the mucous membrane of the large intestine, thereby giving rise to dysenteriform symptoms. A small nematode *Strongyloides stercoralis*, which is found in most tropical countries, has been accredited, on rather slender grounds with similar properties, although it does not appear to burrow into the mucous membrane.

This formidable list does not exhaust the known causes of dysentery. There are the various forms of colitis, which are found in civilized peoples all over the world, the exact aetiology of which still remains obscure. These include mucous colitis, a secretory neurosis of the large bowel, which gives rise to diarrhoea with the passage of much ropy mucus and occasionally, also of blood. Membranous colitis is an exaggerated form of this disorder in which casts of the mucous membrane appear in the stools, accompanied by blood and mucus. Idiopathic ulcerative colitis (*colitis gravis*) is a very severe and sometimes fatal, disease of the colon with the passage of bloodstained mucous discharges, eventually producing severe anaemia, toxæmia and death. It is mainly a disease of early adult life and is liable to remissions and sudden exacerbations. By reasons of its course and manifestations it is liable to be confused with the other forms of bacillary dysentery of which the cause is accurately known. Mercurial colitis is one of the clinical manifestations of mercurial poisoning and closely resembles the above, and a somewhat similar condition is sometimes observed in the uræmic state. Other familiar disorders, such as carcinoma of the large intestine, caecum, colon or rectum, occasionally produce dysenteric symptoms long before their serious nature can be recognized. Polyposis, or multiple adenomata of the large intestine may do the same, and simple polypi in the lower bowel may produce spasmodic contraction and passage of bloodstained mucus. Diverticulitis, a common affection of advancing age, lymphogranuloma of the rectum and Crohn's disease, or chronic catarrhizing enteritis, have also to be reckoned with. Intussusception of the small or large intestine may be associated with amoebic or bacillary dysentery, or, in small children, arise from irritation by a polypus. Submucous lipoma and Meckel's diverticulum may produce a tumour and blood and mucus in the faeces. Finally, tubercular ulceration of the large intestine and septic ulceration of the rectum due to internal haemorrhoids must be included.

Bacillary Dysentery—The bacillary dysenteries are characterized by inflammation of the mucous membrane of the large intestine and occasionally of the terminal portions of the ileum which may lead to superficial necrosis. The symptoms are provoked by efforts of the body to rid itself of the products of this destruction, together with absorption of the exotoxins elaborated by the various dysentery bacilli. Death takes place from dehydration and intoxication. The infection is spread in most tropical countries by contaminated water, food and most probably by the housefly (*Musca domestica*) in those hot countries where this insect abounds. Carriers of dysentery bacilli must also be taken into account. The healthy carrier (that is, one who excretes dysentery bacilli in healthy motions without having suffered from the disease) is rare, but the convalescent carrier is comparatively common. The incubation period varies from three to seven days.

The clinical course of bacillary dysentery is extremely varied and ranges from comparatively mild types to acute fulminating cases with intense toxæmia, in which death takes place within two to three days. The latter type has become increasingly

uncommon. In most tropical countries an explosive diarrhoea attacks most newcomers and is labelled in various places by appropriate synonyms. In Egypt it is familiar as "gippy tummy" and is usually, due to *Shigella sonnei*. It is a fleeting but disagreeable disorder not attended by any serious aftereffects. In the acute type of bacillary dysentery the onset is abrupt and within a few hours there is fever with a temperature of 101°-105° F. The patient suffers from a severe toxæmia and dehydration soon becomes obvious. Sometimes there is vomiting. Within three or four hours violent diarrhoea sets in with severe colic and tenesmus. Blood and mucous discharges are continuous and there is usually incontinence. Abdominal pain and tenderness are severe. The colon is congested, painful and spastic. In children the onset may be heralded by convulsions. Chronic bacillary dysentery is an extremely exhausting, debilitating disease caused by chronic ulceration of the large intestine and was a common sequel in World War I but later became rare.

The complications of bacillary dysentery are dysenteric arthritis, which resembles rheumatoid arthritis but is of a more fleeting character, conjunctivitis, iritis, neuritis and sometimes glomerulonephritis. Occasionally there is peritonitis and massive intraperitoneal serous effusions. The disease is diagnosed by the character and appearance of the stools, the serous and blood-stained mucus, by the isolation on culture of the specific organisms in which special selective media are now employed (Lieson's de-oxycholate citrate agar). The characteristic cellular exudate of the discharges as seen by microscopy such as pus cells and large histiocytes derived from the mucosa, in this picture, are important. In doubtful cases sigmoidoscopy may be employed when the typical granular appearance of the mucosa is distinctive.

Treatment.—The treatment of this group was revolutionized by the introduction of special sulfonamide drugs—sulfaguanidine, sulfaisozidine and sulfadiazine. The former practice of drenching the intestinal tract by saline purgatives has been abandoned. For any severe case rest in bed is imperative, as in *S. shigæ* infections the heart muscle may be damaged by the potent toxins of this organism. All food should be withheld for the first 48 hr, but plentiful draughts of water should be permitted. The usual treatment involves prescribed dosages of sulfaguanidine and if a patient does not respond it is usually advisable to change over to some other sulfonamide, such as sulfaisozidine. It was formerly thought that sulfaguanidine was bacteriostatic because of poor absorption, but it is now known that absorption takes place, though slowly, so that in overdosage toxic symptoms may result, such as obstruction of the renal tubules by crystals, leading to suppression, various toxic rashes and sometimes acute psychosis. If sufficient fluid cannot be absorbed by the mouth then parenteral salines should be given intravenously by drip transfusion. This will abolish the incidence of renal blockage which is especially dangerous in hot countries. Total and differential white blood counts should be made at suitable intervals to give warning of granulocytopenia, which may complicate sulfonamide therapy.

For pain and lack of sleep the physician should have no hesitation in giving morphia injections. Lavage of the lower bowel with hot saline is comforting to the patient and a suppository of coraine affords relief of tenesmus. In *S. shigæ* infections antidiarrhetic antitoxin administered intravenously, if given within the first 24 hr, is still employed with good results. It is of great importance that patients with subacute or chronic bacillary dysentery should not be kept on semistarvation diet or they will develop evidence of hypoproteinaemia. It is therefore necessary to provide after the fifth day a well balanced nutritious diet of high vitamin content and with a sufficiency of animal protein.

Amoebic Dysentery.—The *Endamoeba histolytica* is a protozoan which is essentially a tissue parasite and obtains its nourishment from the cells of the intestinal wall. It occurs in the human body in several stages. In the intestine, the trophozoite or tissue-invasive stage, is 20 μ to 30 μ in diameter, though minute stages 10 μ to 12 μ are often present. There is a characteristic nucleus and a labile protoplasm composed of an inner granular and an outer hyaline zone. By means of pseudopodia the parasite progresses and ingests food, mostly consisting of red blood cor-

pascles and tissue cells. *E. histolytica* has to be distinguished from *E. coli*, and three other species of nonpathogenic amoebae which inhabit the intestinal tract of man.

Cyst formation takes place for the purpose of transmission from one host to another. Before this occurs all food contained in the amoeba is thrown out, a thin cyst wall is formed, and there is one large nucleus, constituting the precystic form. The cysts vary in size from 5 μ to 20 μ in diameter. They contain at first a single nucleus, which soon divides into four, the daughter nuclei separating and taking up separate positions at opposite poles. There are also in the cytoplasm chromatoid bodies and sometimes glycogen vacuoles which show up with iodine. The cysts are formed within the amoebic ulcers and are then passed out in the faeces. They remain viable for some days in water and apparently in this medium are passed on to another individual. Neither precystic forms nor cysts are produced in the metastatic lesions of amoebiasis.

Amoebic dysentery is usually much more chronic and insidious than is the bacillary disease. It also occurs as an endemic or sporadic infection. The incubation period is variable; it may be 60 days or longer, but in the Chicago outbreak of 1933 it was about a week, in some instances. Apart from individuals who manifest the symptoms of dysentery, there are many others in whom the cysts appear in the faeces and these are known as "carriers." In England there are a number of healthy people who harbour the cysts, though indigenous amoebic dysentery is rare. Therefore some believe that there are two strains of *E. histolytica*, one, the large strain, being highly pathogenic, the other, with low invasive powers, not being so.

The pathology of amoebic dysentery consists of ulceration of the large intestine as a result of invasion of the submucosa by *E. histolytica*. Amoebic granulomata are irregular erosions of the mucosa and formations of granulation tissue. The ulcers may be of a large size and solitary, with normal intervening mucosa or may become confluent. Multiple small ulcers covering the whole surface are known as "sea anemone" ulcers. The ulcerations are apt to conglomerate at the flexures.

The clinical picture in amoebic dysentery is extremely variable. It may consist of a trivial affection or be very severe, it may be transient, or last for many years. Two chief types may be distinguished: one with insidious onset commencing with diarrhoea without much general disturbance, the other more acute with abdominal pain, colic and the passage of bloodstained mucous stools. Very acute fulminating attacks are rare. As a rule three or four stools are passed in the day. Incontinence and tenesmus are uncommon. The chronic type is much the more frequent and this manifests itself by frequent remissions and exacerbations with vague abdominal disturbances. There is usually tenderness and induration over the caecum in the right and over the sigmoid in the left iliac fossae. In contrast to the bacillary dysenteries, the faeces are much more offensive, contain much altered blood intermingled with the faecal contents, but in the later stages are dark and fluid and are aptly likened to anchovy sauce but solid faeces with congealed blood and mucus may be passed when the process is quiescent. As a rule there is no fever, but nausea is often present. Vomiting is uncommon. The disease tends to recovery as a rule and is the outcome of the activities of the purgative and the recuperative powers of the intestine. Rare forms are those with fever and toxæmia which are probably due to secondary bacterial infection of the ulcerations. Death takes place either from perforation of the large intestine and consequent peritonitis, from intestinal haemorrhage or from gangrene of the bowel, especially at the site of the flexures. In the chronic stage, amoebic hepatitis frequently supervenes, there is a gradual loss of weight, the skin becomes dry and sallow and introspective neurotic manifestations make their appearance.

In amoebic dysentery there are often long periods of latency which may last a year, or even longer, and it is in these cases that liver abscess may intervene. In others the disease appears to be confined to the caecum (amoebic typhlitis) and may closely simulate appendicitis. Attention has been increasingly drawn to the "amoeboma." This is a tumour composed of hyperplastic granu-

tion tissue occurring at different sites, in the ileocaecal region, the transverse colon, sigmoid flexure or rectum, which closely simulates a malignant growth, and is apt to appear in chronic amoebic dysentery. It may also give rise to a local intussusception which complicates the clinical picture still further. Pericolic amoebic abscesses may also form, but are rare. Complications are amoebic hepatitis (fever, leucocytosis and hepatic pain) and amoebic abscess of the liver and of the lung, rarely of brain or spleen. Amoebic abscess of the epididymis has been reported, while fistulae of the buttocks, perianal amoebic ulcers and abscesses, and similar lesions of the cervix uteri in the female have been described. Amoebic invasion of the skin, producing gangrene, is apt to occur from a para-rectal abscess or from a liver abscess, and to follow on abdominal operation in a subject who is infected with *E. histolytica*. Sometimes these accidents happen in those who have never suffered from clinical amoebic dysentery, but who harbour *E. histolytica* cysts in the faeces.

Apart from the information to be obtained from the history of the patient and character of the stools, absolute diagnosis is founded upon the detection of *E. histolytica* in the faeces. In the acute stage this is comparatively easy when the large active tissue-invading trophozoites can be recognized with ingested red blood corpuscles. They are not always evenly distributed and those portions of the stools containing blood and mucus should be selected. The examination should be conducted while the excreta are warm, since these organisms soon deteriorate and die. It is often more practicable to make scrap preparations by a special instrument (Volkmann's spoon) directly from the rectal mucosa through a proctoscope or sigmoidoscope. In the chronic stages the cysts are found in the diarrhoeic faeces and are often present in enormous numbers, but they tend to vary from day to day and there may often be long periods during which they are absent altogether.

Sigmoidoscopy is most important. By means of this instrument the characteristic ulcers may be demonstrated. These are often of a small size and superficial character. There may be small submucous haemorrhages and, in the chronic stage, minute pittings with crateriform edges giving rise to what is known as the "pisskin appearance". As a rule, amoebic lesions are visible in the lower rectum in the vicinity of Houston's valves and therefore can easily be seen through a simple proctoscope.

Treatment.—There is one drug, emetine, which is specific for amoebic dysentery. This is the alkaloid of *ipecaacuanha*, which destroys the parasite in very dilute solutions (1:1,000,000). In the acute stages, emetine hydrochloride is injected deep subcutaneously. Although this method controls the acute manifestations, it does not eradicate the infection and has no effect upon *E. histolytica* cysts. For this purpose emetine bismuthous iodide is given. This compound is decomposed in the intestinal tract into bismuth sulphide and emetine is liberated on the surface of the ulcers. It is best given in enteric or gelatine coated capsules. A new dispersible form has been prepared which is very efficacious. The dose is spread over a period of 10 to 12 days. The patient should be confined to bed on a light diet and the drug should be administered at 10 p.m. No food should be taken after 6 p.m. and a sedative should be taken one-half hour before the specific drug. Another amoebicidal drug is quinoxyl (yatren) given in the form of retention enemas. The bowel should be cleansed with a 2% sodium-bicarbonate solution beforehand. Other drugs are carbarsone, stovarsol and diodoquin. The latter, another quinoxyl compound, is useful in clearing up the "carrier" state. Other specific drugs in the treatment of the dysenteries are atabrine (mepacrine) in giardiasis, paludrine in malarial dysentery, neostibosan in leishmaniasis and sodium antimony tartrate in bilharziasis. DYSON, SIR FRANK WATSON (1868-1939), Brit. astronomer, was born at Ashby-de-la-Zouch, Leicestershire, on Jan. 8, 1868, and was educated at Bradford grammar school and Trinity college, Cambridge. In 1891, he became chief assistant at the Royal observatory, Greenwich, and in 1905 was made astronomer royal of Scotland, a position which he held until his return to Greenwich as astronomer royal of England (1910-33). From 1899 to 1905 he was secretary of the Royal Astronomical society. He was elected F.R.S. in 1901, subsequently serving on the council, and was in 1921 awarded the royal medal for his numerous contributions to astronomy, and especially for his important investigations of the distribution and movements of stars and the bearing of these upon the structure of the stellar universe. His observations of the spectrum of the corona and chromosphere, during eclipses of the sun, were published in *Determination of Wave Length from Spectra Obtained at the Total Solar Eclipses of 1900, 1901 and 1905* (1906). Knighted in 1915, he was created K.B.E. in 1926. He also wrote *Astronomy, a Handy Manual for Students and Others* (1912).

DYSPEPSIA, difficult or painful digestion, may be of nervous origin, the result of poor food habits, of reflex origin due to disorders of organs other than those of the gastrointestinal tract or to various diseases or disorders of the alimentary system. See also ALIMENTARY SYSTEM, DISEASES OF.

DYSPROSIUM (symbol Dy, atomic number 66, atomic weight 162.46, stable isotopes Dy^{156} [0.052%], Dy^{158} [0.090%], Dy^{160} [0.1%], Dy^{161} [21.1%], Dy^{162} [26.6%], Dy^{163} [24.8%], Dy^{164} [27.3%]) is a metallic element of the rare earth group. The name is from the Greek *dysprositos*, meaning hard to get at. In 1886 L. de Boissaudran deposited a sealed paper with the Académie des Sciences, it was opened at a later date and read at his request. It contained a statement that a new element possessing characteristic absorption spectra had been separated from cerium. The oxide was obtained fairly pure for the first time in 1906 by G. Urbain. The element occurs along with erbium, holmium, etc., in the minerals gadolinite, euxenite, xenotime, etc. It is usually obtained free from the neighbouring rare earths by a fractional crystallization of the bromates. Since 1945 rapid separations have been obtained by means of adsorption columns. It forms a white oxide (Dy_2O_3) which dissolves in many acids to form yellowish green solutions which show strong characteristic absorption spectra. Its salts are strongly paramagnetic. Minute amounts of its salts have been reduced to metal by means of thermo reduction with alkali metals. The metal crystallizes in the hexagonal close packed system ($a=3.578\text{Å}$, $c=5.648\text{Å}$) with a calculated density of 8.764. See RARE EARTHS. (F. H. Sp.)

DYSTELEOLOGY, a modern word invented by Ernst Haeckel (*Evolution of Man*) for the doctrine of purposelessness, as opposed to the philosophical doctrine of design (Teleology).

DYVEKE see v. CHRISTIAN II, KING OF DENMARK.

DZERZHINSKY, FELIX EDMUNDOWICH (1877-1926), Russian politician of Polish descent, was born at Vilna. He joined the Social Democratic party of Lithuania in 1895, and two years later was arrested and banished to Siberia for political agitation. In 1899 he escaped, was rearrested in the following year and in 1902 again escaped. After he had taken part in the revolution of 1905 there followed further years of banishment until 1912, when he returned to Warsaw, was arrested again and sentenced to nine years' hard labour. After the revolution of March 1917, he was released and became a member of the military revolutionary committee which organized the bolshevik revolution. In Dec. 1917 he organized and became chairman of the Cheka, or secret police afterwar the OGPU. He was appointed commissar of the home department in 1919. The organization of the Cheka was found to be so complete that it was possible to dispense with Dzerzhinsky's supervision and in 1921 he was transferred to the commissariat of transport, where

he carried out an exhaustive reform of the railways. In 1924, after the party dispute on policy at the time of Lenin's death, Dzerzhinsky was placed at the head of the supreme economic council. He died in July, 1926.

DZUNGARIA, **DSONGARIA** or **JUNGARIA**, a former Mongolian kingdom of central Asia, raised to its highest pitch by Kaldan or Busutu Khan in the latter half of the 17th century, but completely destroyed by Chinese invasion about 1757-59. It derived its name from the Dsongars or Songars, who were so called be-

cause they formed the left wing (*dson*, left, *gar*, hand) of the Mongolian army. Its widest limit included Kashgar, Yarkand, Khotan, the whole region of the T'ien Shan (or T'ien shan) mountains, and the greater proportion of that part of central Asia which extends from 35° to 50°N and from 72° to 97°E. The name, however, is more properly applied only to the later Chinese province of T'ien Shan pei lu and the country watered by the Ili. As a political or geographical term it has practically disappeared from the map.

E THE fifth letter of the alphabet, answers to Semitic **א**, Greek **Ε** or **Ϝ**, Latin **E**. Forms in use at Corinth were **β** or **B**. The Lydian form was **Ϝ** and there was an alternative form **Ϝ** in use in the Faliscan and Latin alphabets. The uncial form was from the 4th century A.D. rounded **Ϝ** and the cursive form was also round, **Ϝ**. From these developed the Carolingian **E** from which the modern minuscule **e** is derived.

The sound represented by the letter was a low front vowel corresponding, though inexact, to the sound of English **a** in *take*. The latter is a diphthong whereas **e** represented an unmixed vowel sound, such as that heard in French *tête* or *été*. In Greek

ground of that formerly represented by **e**, so the latter moved upward, encroaching upon and occupying the territory of the sound of **i**, which became a diphthong. The sound of English long **e** is now a close high palatal vowel, as in *be*, that of short **e** a more open and less high front vowel, as in *bed*, that has not to any great extent shifted from what may be called its original position (*cf.* the sounds of French *été* and English *bed*). When followed by **r** the sound is modified and is less high, as in *here*. In the word *there* the vowel has the same sound as that of **a** in *here*. In many English words a mute final **e** is employed as a device to mark the fact that the preceding vowel is long, e.g., *take*, *wine*, *stone*. This occurs only when the final **e** is separated from the long vowel by a single consonant. Again, in words such as *added*, *rotten*, the letter represents little more than a voice glide.

In music, **E** is the fifth note of the musical alphabet and the third degree of the "natural scale" of **C**. Its syllabic name, employed in France and Italy, is *mi*.

EA (written by means of two signs signifying "house" and "water"), in the Babylonian religion was the god of wisdom and patron deity of Eridu, situated in ancient times at the head of the Persian gulf but now at some distance from the gulf. Eridu "the good city," was one of the oldest settlements in the Euphrates valley, and is now represented by the mounds known as Abu Shahrein. Whether **Ea** (or **A** **e**) represents the real pronunciation of his name we do not know. The name is rendered by 'Aô in the theogonies of Damascus and by *Ωαννης* in the fragments of Berossus. All attempts to connect **Ea** with *Yah* and *Yahweh* are idle conjectures without any substantial basis. The original Sumerian name of this god is *En Ki*, "lord of the earth," referring to his abode in the *Apsu*, or rather sea, from which springs and rivers were supposed to flow. He is never connected with the salt water seas. **Ea** is not found earlier than the 22nd century B.C. He is figured as a man covered with the body of a fish, and this representation, as likewise the name of his temple *E apsu*, "house of the watery deep," points decidedly to his character as a god of the waters (*see* *OANNES*). Of his cult at Eridu, which reverts to the oldest period of Babylonian history, nothing definite is known. Incantations, involving ceremonial rites, in which water as a sacred element played a prominent part, formed a feature of his worship. Eridu never played an important political rôle. The prominence of the **Ea** cult led to the survival of Eridu as a sacred city, long after it had ceased to have any significance as a political centre, c. 2200 B.C. Myths in which **Ea** figures prominently indicate that **Ea** was regarded as the protector and teacher of mankind. He is essentially a god of civilization, the creator of man and of the world in general. Traces of this view appear in the *Marduk* epic celebrating the achievements of this god, and the **Ea** cult at Eridu is connected with that of *Marduk*, since *Marduk* is generally termed the son of **Ea** who derives his powers from the voluntary abdication of the father in favour of his son.

Ea acquires his permanent place in the pantheon as the third figure in the triad, the two other members of which were *Anu* (*q v*) and *Enlil* (*Bêl*). To him was assigned the control of the watery element, and in this capacity he becomes the *šar apsi*, i.e., king of the *Apsu* or "the deep," an ocean beneath the earth. Since the gathering place of the dead, known as *Aralu*, was situated near the confines of the *Apsu*, he was also designated as *En Ki*, i.e., "lord of that which is below," in contrast to *Anu*, who was the lord of the "above" or the heavens. The cult of **Ea** extended throughout Babylonia and Assyria. Temples and shrines were erected in his honour, e.g., at Nippur, Girsu, Ur, Babylon, Sippar and Nineveh, and the numerous epithets given to him, as well as the various forms under which the god appears, alike bear witness to the popularity which he enjoyed from the earliest to the latest period of Babylonian Assyrian history. The consort of **Ea**, known as *Damkina*, "lady of that which is below" or *Nin Ki*, having the same meaning, or *Damgal-nunna*, "great lady

THE DEVELOPMENT OF THE LETTER **E** FROM THE PHOENICIAN THROUGH CLASSICAL LATIN TO THE PRESENT FORM

e stood for a short, close vowel as opposed to **η** whose sound was long and open, although in all local alphabets, especially in early times, this distinction was not exactly observed. In Attic Greek the long, close sound was expressed by **ε̄**. In the Latin alphabet the letter **E** did duty for all shades of the sound, long or short, close or open.

In English an extensive change took place in the sound of the long vowel during and after the later Middle English period (probably between the 15th and 17th centuries). Just as the sound represented by **a** moved forward till it now covers the

of the prince," plays a part merely in association with her lord

BIBLIOGRAPHY—Tentative excavations were made at Endu in 1919 by H. R. Hall, see "Ur and Endu," *Journal of Egyptian Archaeology*, IX (1921), and in 1918 by R. Campbell Thompson, "The British Museum Excavations at Abu Shahrein," *Archaeologia* LXX (1920)

EADBALD (ǣðbʰwɪld) (d. 640), king of Kent, succeeded on the death of his father Æthelbert in 616. He had not been influenced by the teaching of the Christian missionaries, and on his accession he followed the heathen custom and married his father's widow. After his subsequent conversion by Laurentius, archbishop of Canterbury, he recalled the bishops Mellitus and Justus, who had fled from his persecution, and built a church dedicated to the Virgin at Canterbury. He arranged a marriage between his sister Æthelburh and Edwin of Northumbria, on whose defeat and death in 633 he received his sister and Paulinus, whom he had sent with her, and offered the latter the bishopric of Rochester. After his conversion Eadbald ceased to live with his first wife, and married Emma, a Frankish princess. He died on Jan 20, 640.

EADMER or EDMER (c. 1060–1124), English historian and ecclesiastic, was probably of English parentage. At the monastery of Christ church, Canterbury, he met Anselm, to whom he served as assistant when Anselm became archbishop of Canterbury in 1093. In 1120 he was nominated archbishop of St. Andrew's, but the Scots refused to recognize the authority of Canterbury. He died probably in 1124. His most important work is the *Historiae Novorum*, dealing with the history of England, mainly ecclesiastical, between 1066 and 1122.

EADS, JAMES BUCHANAN (1820–1887), U.S. engineer, was born at Lawrenceburg, Ind., on May 23, 1820. His first engineering work of any importance was in raising sunken steamers. In 1845 he established glassworks in St. Louis. During the Civil War he constructed ironclad steamers and mortar boats for the federal government. His next important engineering achievement was the construction of the great steel arch bridge across the Mississippi at St. Louis upon which he was engaged from 1867 till 1874. The work, however, upon which his reputation principally rests was his deepening and fixing the channel at the mouth of the Mississippi by means of jetties, whereby the narrowed stream was made to scour out its own channel and carry the sediment out to sea. Shortly before his death he projected a scheme for a ship railway across the isthmus of Tehuantepec, in lieu of an isthmian canal. He died at Nassau, in the Bahamas, on March 8, 1887.

EAGLE, the name given to the larger diurnal birds of prey, in the family Accipitridae, with feathered head, strongly hooked beak, great talons and keen vision. They range throughout the world, and are famous for their powerful, stately, soaring flight. Most of them belong to the subfamily Buteoninae, typified by the European buzzards and large American hawks (*Buteo*).

The typical eagles (*Aquila*) include eight species with "booted" legs, feathered to the toes. The best known is the golden eagle (*A. chrysaetos*), inhabiting mountainous or rocky regions of Europe, Asia and North America. They build a huge eyrie of sticks on cliffs or tall trees, returning year after year to lay one to four large white eggs mottled with brown. The young are clad in white down, assume the dark brown juvenile plumage after ten weeks, and molt annually until the adult golden brown is acquired at four years. Kirghiz Tatars used the golden eagle to capture antelopes, but in Europe, during the height of falconry, it was flown only by kings. Of eight geographic races, the typical form is found in Europe, another (*A. c. fulva*) breeds in Scotland and the Hebrides, while a third (*A. c. canadensis*) is familiar in North America from Alaska and northeastern Canada south in the mountains to North Carolina, Tennessee and central Mexico, especially in the western mountains. Other races are found in Spain and northwest Africa, Japan and Korea and Asia. Related species include the spotted or imperial eagle (*A. heliaca*), southern Europe to China, the tawny eagle (*A. rapax*), Africa and India, and several smaller species in Asia, Africa and eastern Europe.

The sea eagles (*Haliaeetus*) range all continents except South

America, and may be known from typical eagles by the naked tarsus or lower leg. They generally eat fish, and are largely robbers and scavengers. Of the eight species, the noble-looking bald eagle (*H. leucocephalus*), national emblem of the United States, is confined to North America. The typical race breeds in the southern United States and northern Mexico, while a larger form (*H. l. washingtonensis*) occurs from Connecticut, the Great Lakes and Washington to northern Canada and Alaska. The eyrie is a huge mass of sticks atop a large tree or pinnacle of rock,

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

within easy flight of sea, lake or stream, one to three eggs hatch in 35 days, both parents sharing incubation and care of young. The smoky gray down is replaced by dark brown juvenile plumage in about eight weeks, and the pure white head and tail are assumed in the fourth year. The magnificent white-tailed or gray sea eagle (*H. albicilla*), from Iceland to Japan, formerly bred in the northern British Isles and Egypt, and is casual in the Aleutians, accidental off Massachusetts. The African sea eagle or river eagle (*H. vocifer*) is like the bald eagle, but the white of the head extends over breast and upper back. The white-bellied sea eagle (*H. leucogaster*) occurs in southeastern Asia, Australia and western Polynesia. Other striking species are found in Kamchatka, Korea, Madagascar and from southern Russia to northern Burma. Two allied species of fishing eagles (*Icthyophaga*) range from India through the Malay to the Philippines, while the large dark wedge-tailed eagle (*Uroaetus australianus*) lives in Australia.

Among the largest, most powerful birds of prey are the harpy eagles (*Harpyia*), six genera and seven species occurring in South America, one in the Philippines and one in New Guinea.

Five species of smaller hawk-eagles (*Hieraaetus*) inhabit the old world. Six species of crested hawk-eagles (*Spiraeetus*) are recognized, three in Central and South America, three in southeastern Asia, the Malays, Philippines and Japan, and four genera, each with a single species, including the large martial eagle (*Polemaetus*), occur in Africa.

The Brazilian eagle (*Hypomorphus urubitinga*) is a large black buzzard or hawk, ranging from Mexico to southern South America. The Chilean eagle (*Geranoetus melanoleucus*) occurs in the Andes from Venezuela to the Straits of Magellan, east to southern Brazil and eastern Argentina.

Quite different from the aforementioned eagles are 5 genera and 13 species of smaller birds of prey belonging to the subfamily Circetinae, confined to the old world. These include the amazing, batlike, bob-tailed bateleur eagle (*Terathopius ecaudatus*) of Africa, the harrier eagles (*Circus*) of Africa, Asia and southern Europe, and the serpent eagles of southeastern Asia and the Malays and Philippines (*Sporus*), central Africa (*Dryotrochus*) and Madagascar (*Entrochus*).

Two old world vultures, subfamily Aegypinae, have been known as eagles, their feathered heads being quite different from naked heads of other vultures. One is the famous bearded vulture or lammergeier (*Gypaetus barbatus*), living in mountains of southern Europe, central Asia and Africa. The other is the vulture fish eagle (*Gypohierax angolensis*), a striking white and black bird of central west Africa. (See LAMMERGEIER.)

See C. W. R. Knight, *The Golden Eagle* (1927), F. H. Herrick, *American Eagle* (1934).

EAGLE GROVE, a city of Wright county, Iowa, U.S.A., 94 mi N of Des Moines. It is served by the Chicago and North Western and the Chicago Great Western railways. Pop. (1950) 4,167. It is a farm crops processing centre with soybean and

THE GOLDEN EAGLE

The golden eagle (*Aquila chrysaetos*) found over a large portion of the northern hemisphere. It is the largest of the birds of prey trained for falconry and has been used in Asia, especially in India, for taking bustards, antelopes, hares, foxes, and it is said even larger animals such as wild goats and wolves.

GOLDEN EAGLE WITH PREY

1 and 2 A female golden eagle, trained for falconry, shown here killing a rabbit. Training an eagle is a formidable task. Owing to its extreme ferocity when deprived of its prey, and to its slowness in turning in the air, the attempt is seldom made to train the eagle for falconry.

animal protein processing plants, fertilizer and livestock products companies and a field seed treatment plant.

EAGLE OWL (*Bubo luteo*), an owl inhabiting Europe and Asia, though only a straggler in most of Great Britain, and characterized by its large size and the two tufts of feathers on the head. It is allied to the great horned owl (*B. virginianus*) of North America, but is larger. On the northwest coast of the United States the latter is represented by the dusky horned owl (*B. v. saturnatus*), a very dark-colored race. The arctic horned owl (*B. v. anapocanthus*) is lighter colored. In Lower California there is a small, light colored race, the dwarf horned owl (*B. v. elachistus*). Other races occur in eastern Canada (*B. v. heterocnemis*) mountainous western Canada (*B. v. lagophonus*), coast of Alaska (*B. v. alpinus*), northern Great Plains to northeastern California (*B. v. occidentalis*), U.S. coastal mountains (*B. v. pacificus*), desert southwest (*B. v. pallidus*) and southward.

EAGLE PASS, a city of southwestern Texas, U.S., on the Rio Grande opposite Piedras Negras, Mex., a port of entry and the county seat of Maverick county. It is served by the Southern Pacific railway. Pop. (1950) 7,247. Stock, feed, cotton and vegetables (notably spinach, tomatoes and onions) are raised in the surrounding country, and coal and gas are mined near by. The city was settled about 1846 and incorporated in 1905.

EAKINS, THOMAS (1844–1916), U.S. portrait and figure painter, was born at Philadelphia, Pa., on July 25, 1844. A pupil of J. L. Gerome, in the Ecole des Beaux Arts, Paris, and also of Leon Bonnat, besides working in the studio of the sculptor Augustus Dumont, he became a prolific portrait painter. He returned to Philadelphia in 1870, opened his own studio and began the study of anatomy. In 1873 he became professor of anatomy at the schools of the Pennsylvania Academy of the Fine Arts in Philadelphia, where he remained for a number of years. Eakins also painted genre pictures, sending to the Centennial exhibition at Philadelphia, in 1876, the "Chess Players," now in the Metropolitan Museum of Art, New York. A large canvas, "The Surgical Clinic of Professor Gross," owned by Jefferson Medical college, Philadelphia, contains life sized figures and portrays the demonstration of a surgical operation to a group of medical students. Eakins, with his pupil, Samuel Murray (1870–1941), modelled the heroic "Prophets" for the Witherspoon building, Philadelphia, and his work in painting has a sculptural quality. Eakins experimented in many directions, depicting on canvas modern athletic sports, the Negro and early American life, but he is best known by his portraits. He died in Philadelphia, June 25, 1916.

EALING, a municipal and parliamentary borough of Middlesex, Eng., suburban to London, 9 mi. W. of St. Paul's cathedral, on the highroad to Uxbridge, served by the Western Region railway and the London Passenger Transport board. Pop. (est. 1938) 161,000. Area 13.98 sq. mi.

The borough was considerably enlarged in 1926 by the addition of the urban districts of Hanwell and Greenford, and further additions in 1928 made it one of the largest noncounty boroughs. The parish church of St. Mary (rebuilt c. 1870) contains many interesting tombs. The church of All Saints (1905) commemorates Spencer Perceval, prime minister, who was assassinated in the house of commons in 1812 and who lived in Ealing. It was erected under the will of his daughter Frederica, a resident of Ealing. The tower of Holy Cross, Greenford, has a timber structure of the 13th century. Ealing has 979 ac. of parks, recreation grounds and open spaces under its control, including the ancient common (47 ac.), Walpole park (30 ac.), Pitsanger park (26 ac.) and others. Gunnersbury park (180 ac.), with two large mansions, was purchased in 1925 from the Rothschild family by the Ealing and Acton borough councils, with whom it is also shared by the borough of Brentford and Chiswick. Among former owners of the property was Princess Amelia, daughter of George II, who lived there from 1761 till her death in 1786. The name of Gunnersbury is said to be traceable to the residence there of Gumlinda, niece of King Canute. The manor of Ealing early belonged to the see of London. Ealing, which was incorporated in 1901, has a technical institute and art school.

It returns one member to parliament.

EAR, ANATOMY OF The human ear is divided into three parts—external, middle and internal. The external ear consists of the auricle and the external auditory meatus (fig. 1). The auricle is formed by a yellow fibrocartilage covered by skin. Round the margin in its upper three quarters is a rim called helix in which is often seen a little prominence known as Darwin's

FROM CUNNINGHAM TEXT BOOK OF ANATOMY PERMITS FOR THE OXFORD MEDICAL PUBLICATION

FIG. 1.—DIAGRAMMATIC VIEW OF THE ORGAN OF HEARING SHOWING THE RELATIONS OF THE EXTERNAL, THE MIDDLE AND THE INTERNAL EAR

tubercle, representing the folded over apex of a pricked-eared ancestor. Concentric with the helix and nearer the meatus is the antihelix which, above, divides into two limbs. Surrounded by the antihelix is a deep fossa known as the concha, from whose anterior part the external meatus passes inward into the skull. Overlapping the meatus from in front is a flap called the tragus, and below and behind it another smaller flap, the antitragus. The lower part of the auricle is the lobule, which contains no cartilage. The auricle can be slightly moved by the anterior, superior and posterior auricular muscles. The external auditory meatus is a tube about an inch long, its outer third being cartilaginous and its inner two thirds bony. It is lined in its whole length by skin, the sweat glands of which are modified to secrete the wax or cerumen. Internally it is closed by the tympanic membrane or drumskin.

The middle ear, or tympanum (fig. 1), is a small cavity in the temporal bone. The Eustachian tube runs thence forward, inward and downward, to open into the nasopharynx, and so admits air into the tympanum. From the upper part of the posterior wall of the tympanum, an opening leads backward into the mastoid antrum and so into the air cells of the mastoid process. Lower down is a little pyramid which contains the stapedial muscle, and at the base of this is a small opening for the chorda tympani to come through from the facial nerve. The roof is formed by a very thin plate of bone, which separates the cavity from the middle fossa of the skull. Below the roof the upper part of the tympanum is somewhat constricted off from the rest, and to this part the term "attic" is often applied. The floor is a mere groove formed by the meeting of the external and internal walls. The outer wall is largely occupied by the tympanic membrane (fig. 1), which entirely separates the middle ear from the external auditory meatus. It is circular, and so placed that it slopes from above, downward and inward, and from behind, forward and inward. Externally it is lined by skin, internally by mucous membrane, while between the two is a firm fibrous tissue, convex inward about its centre to form the umbo, or navel.

The inner wall of the tympanic cavity shows a promontory caused by the cochlea and grooved by the tympanic plexus of nerves, above and behind it is the oval window, while below and behind, the round window is seen, closed by a membrane. Curving round, above and behind the promontory and windows is a ridge caused by the Fallopian aqueduct, or canal, for the facial nerve. The whole tympanum is about half an inch from before backward

MEDIUM MAGNIFICATION.

vibrations is caught by the external mobile flaps called "auricles," or "pinnae," and less so by applying directly to the skull and the body. From the auricle the vibrations enter the external auditory meatus,

passing over to the tympanic, or eardrum, membrane and finally to the chain of auditory ossicles. These latter act as an elastic bridge along which the sound is transmitted to the stirrup's footplate, classically fitted into the oval window. The other opening, the round window, is in turn closed off by an elastic "secondary tympanic membrane." The perilymphatic fluid filling the rigid bony labyrinth because of its incompressibility, has only one exit, the round window, by which it may give way whenever the footplate of the stirrup is pushed in, or is sucked in when the footplate is pulled out. The oscillatory movements thus caused pass through the two scale of the bony cochlea, taking a shortcut through one or the other segment of the basilar membrane, closer to the base in the sounds of high pitch and nearer the apex of the cochlea in low-pitched sounds. The remaining sound vibrations pass through the intermediate segments. (See BASILAR MEMBRANE.)

Embryology.—The auricle is formed from six tubercles which appear around the first pharyngeal groove, or gill cleft. Those for the tragus and anterior part of the helix belong to the first, or mandibular, arch, while those for the antitragus, antihelix and lobule come from the second, or hyoid, arch. The tubercle for the helix is dorsal to the end of the cleft where the two arches join. The external auditory meatus, tympanum and Eustachian tube are remnants of the hyomandibular cleft, the tympanic membrane being a remnant of the cleft membrane and therefore lined by ectoderm outside and endoderm inside. The auditory ossicles are modified bones of the visceral skeleton of lower vertebrates (e.g., fishes, etc.). The internal ear first appears as a pit from the cephalic ectoderm, the mouth of which in mammals closes up, to leave a pear-shaped cavity. The lower part of the vesicle grows forward and becomes the cochlea, while from the upper part three hollow circular plates grow out, the central parts of which disappear, leaving the margin as the semicircular canals. Subsequently, constrictions appear in the vesicle marking off the sacculus and utricle. From the surrounding mesoderm the petrous bone is formed by a process of chondrification and ossification.

Comparative Anatomy.—The ectodermal invagination of the internal ear has probably a common origin with the organs of the lateral line of fishes. In the lower forms the endolymphatic duct retains its communication with the exterior on the dorsum of the head, and in some elasmobranchs the opening is wide enough to allow the passage of particles of sand into the sacculus. In certain teleostean fishes the swim bladder forms a secondary communication with the internal ear by means of special ossicles. Among the Cyclostomata the external semicircular canals are wanting, *Petromyzon* has the superior and posterior only, while in *Myxine* these two appear to be fused. In higher types the three canals are constant. Concretions of carbonate of lime are present in the internal ears of almost all vertebrates, when these are very small they are called otoconia, but when, as in most of the teleostean fishes, they form huge concretions, they are spoken of as otoliths. One shark, *Squalus*, has sand instead of otoconia. The utricle, sacculus, semicircular canals, endolymphatic duct and a short lagena are the only parts of the ear present in fishes.

The Amphibia (*q.v.*) have an important sensory area at the base of the lagena, it is probably the first rudiment of a true cochlea. The

FIG. 5.—TRANSVERSE SECTION THROUGH BASILAR PAPILLA OR CORTI'S ORGAN FROM THE CENTRAL COIL OF COCHLEA.

endolymphatic duct has lost its communication with the skin, but it is frequently prolonged into the skull and along the spinal canal, from which it protrudes, through the intervertebral foramina, bulging into the column. This is the case in the common frog. In this class the tympanum and Eustachian tube are not developed, the tympanic membrane lies flush with the skin of the side of the head, and the sound waves are transmitted from it to the internal ear by a single bony rod—the columella.

In the Reptilia the internal ear passes through a great range of development. In the Chelonians and Ophidians the cochlea is as rudimentary as in the Amphibia, but in the higher forms (Crocodilia) there is a lengthened and slightly twisted cochlea, at the end of which the lagena forms a minute terminal appendage. At the same time indications of the sclerotic tympani and vestibuli appear. As in the Amphibia the endolymphatic duct sometimes extends into the cranial cavity and on to other parts of the body. Snakes have no tympanic membrane. In the birds the cochlea resembles that of the crocodiles, but the posterior semicircular canal above the superior where they join. In certain lizards and birds (owls) a small fold of skin represents an external ear. In monotremes the internal ear is reptilian, but above them the mammal is always have a spirally twisted cochlea, the number of turns varying from one and a half in the Cetacea to nearly five in the rodent *Corylogerys*. The lagena is reduced to a mere vestige. The organ of Corti is peculiar to mammals and the single columella of the middle ear is replaced by the three ossicles already described. In some mammals, especially Carnivora, the middle ear is enlarged to form the tympanic bulla, but the mastoid cells are peculiar to man.

EAR, NOSE AND THROAT, DISEASES OF THE

Though diseases of these parts are considered separately, the parts themselves are closely connected by the Eustachian tube.

Diseases of the Ear.—The ear consists of three parts, each with its own particular diseases: the outer ear, the middle ear and the internal ear.

The outer ear projects from the side of the head and includes the ear canal. Because of its exposed position, frostbite of the outer ear is common in freezing weather: the edge of the ear turns white and becomes insensitive to touch. The frozen part should be thawed out gradually in a cool room, and with cold water compresses applied to the ear until the colour returns, to prevent permanent damage to the tissues.

Accumulation of wax in the block the ear canal producing a painless impairment in hearing. This is a rather common cause for

moderate degrees of deafness, and is relieved by removing the wax. This can be done by syringing with warm water, or the experienced ear physician (otologist) may use instruments in the ear canal.

Skin infections of the outer ear canal may be caused by various micro organisms or moulds which are carried in by water or from the ear. These canal infections are especially common in the tropics. The ear feels full, with a malodorous discharge, and sometimes pain or itching. The treatment is to remove with great care all most accumulations from the depth of the ear canal, followed by the use of appropriate medication against the particular causative micro organism.

Boils of the ear canal, like boils elsewhere, are due to infection in a hair follicle by *Staphylococcus aureus*. In the ear canal a boil is exceedingly painful and tender with swelling that may block the canal and temporarily impair the hearing. Heat and the use of an antiseptic solution are the treatment.

Eczema of the ear canal produces a reddened scaly appearance around the opening, with severe itching and a slight watery discharge. In some cases eczema is due to an allergy to feathers or to a food, and disappears when the particular substance is avoided.

Tumours of the outer ear include osteomas, which are small bony growths that sometimes occur in the depth of the ear canal after years of swimming in cold water and carcinoma (cancer) of the skin of the ear. "Skin cancer begins as a small ulcer covered by a scab, it fails to heal completely, and instead slowly increases in size. If removed early and completely, skin cancers are curable.

The middle ear is a small cavity enclosed in bone and filled with air. It connects with the upper part of the throat through the Eustachian tube. To keep the air pressure in the middle ear equalized with the air pressure outside, the Eustachian tube opens momentary on swallowing or yawning. This becomes very important in rapid changes of altitude, for if the air pressure is not equalized severe pain in the ear with impaired hearing results.

The middle ear cavity is separated from the outer ear canal by the very thin transparent drum membrane, the purpose of which is to vibrate in response to sound that enters the outer ear. A chain of tiny middle ear bones attached to the drum membrane carries the sound vibrations across the middle ear cavity to the internal ear, which is filled with fluid. When the fluid in the internal ear vibrates, it stimulates the endings of the hearing nerve, which carries the message to the brain.

Perforation of the drum membrane can result from a sudden change in air pressure. It can also result from infection in the middle ear cavity (abscessed ear). A perforated drum membrane cannot vibrate normally and in impairment of hearing results. Some perforations heal by themselves, others can be caused to heal by treatment, while some require the permanent use of a hearing aid.

Infection of the middle ear, sometimes called abscessed ear, is the result of micro organisms, especially the *Streptococcus* reaching the middle ear cavity from the throat through the Eustachian tube. There is a severe earache with fever and impaired hearing. If the pus bursts through the drum membrane, the ear begins to drain and the pain becomes less. Infections of the middle ear are important because they may spread to near by important structures, including the brain cavity and brain, the internal ear, the mastoid bone, and the facial nerve that supplies the muscles of the face. Fortunately these middle ear infections, when acute, clear up quickly with the use of sulfa drugs, penicillin or other antibiotic drugs. Chronic infections of the middle ear cavity are a different problem, and may require surgery to remove the disease and prevent extension to the brain cavity or other near by structures. Chronic middle ear infections also cause a permanent impairment in hearing by preventing the transmission of sound across the middle ear cavity to the internal ear.

The internal ear, enclosed in bone and filled with fluid, is also known as the labyrinth since it consists of a complicated arrangement of cavities. Part of the labyrinth is to maintain equilibrium, and part is for hearing. Various disturbances in the labyrinth can therefore affect the balance as well as the hearing. When the fluid in the labyrinth is under increased pressure, there are attacks of dizziness, with impaired hearing, and head noises. If the dizzy attack is severe the victim falls down and is nauseated. This condition is called Ménière's disease, after Emile Antoine Ménière, who first described it.

Degeneration of the hearing nerve is a common cause of deafness. It may be the result of a severe infection with a high fever. It can result from large doses of certain drugs like quinine. It very often comes after exposure to loud noise, in certain industries ("boiler-makers' deafness") or in military personnel. Degeneration of the hearing nerve also occurs with advancing age. As a rule a degenerated hearing nerve cannot be helped by medical treatment.

Otosclerosis is a common cause of progressive deafness beginning in early adult life. The loss of hearing is due to a small growth of bone that blocks the passage of sound vibrations to the internal ear. In some cases of otosclerosis the hearing can be improved by an operation to construct a new opening for the passage of sound, called the fenestration operation.

Diseases of the Nose—The nasal cavity is lined by a mucous membrane which covers an air-filled cavity called the antrum. The common cold is an infection of the nasal mucous membrane caused, it is believed, by a virus, or in some cases certain micro-organisms. The inflamed mucous membrane is swollen, with obstruction to breathing, and there is an increased production of mucus from the membrane. When severe, the infection may result in an accumulation of mucus and pus in one of the antrums with pain, headache and increased discharge.

Allergy of the nasal mucous membrane is due to sensitization to a particular substance of a protein nature that is inhaled or is eaten. House dust, animal hair, feathers and the pollens of certain weeds and grasses ("hay fever") are common causes for nasal allergy.

Nasal polyps are soft, gelatinous, fleshy growths that develop from the mucous membrane in some cases of nasal allergy, and block the nasal cavity.

Nosebleed is a common condition following an injury or sometimes occurring spontaneously. Sitting upright with the head bent forward and both nostrils plugged with a ball of cotton and held firmly shut between the thumb and finger will stop most nosebleeds.

Chronic infection of a sinus produces a drainage of thick mucus and pus, from the nose into the throat, sometimes with pain and headache. Some of the chronic sinus infections are the result of an allergic condition in the nose. Others are the result of an abscessed tooth that breaks into the sinus, or of severe head colds. Improved drainage, either by improving an allergic condition, or by irrigating the sinus, or by an operation, is the accepted treatment for chronic sinusitis.

Malignant tumours (cancer) of the nose or sinuses are not common. The first symptoms are a bloody discharge, with obstruction to breathing. The diagnosis is made by removing a small piece of the suspicious tissue and examining it under a microscope.

The treatment of cancer of the nose is to remove the tumour early and completely.

Diseases of the Throat—The throat is the passage that connects the nose and mouth with windpipe and lungs. To help protect the body against micro organisms that enter through the nose and mouth, the throat is supplied with masses of lymphoid tissue around the base of the tongue, and the roof and sides of the throat. The tonsils are large masses of lymphoid tissue, lying on either side of the entrance to the throat. Acute tonsillitis is due to infection, usually with streptococci, with severe soreness, swelling and fever. Quinsy, or sore throat, is due to infection behind the tonsil, forming an abscess, with even greater soreness and pain and great difficulty in swallowing. Diphtheria of the tonsils and throat must always be suspected in a sore throat that lasts more than a few days, for if treated early with antitoxin, recovery is rapid, whereas untreated diphtheria is often fatal. Scarlet fever is a particularly severe form of tonsillitis with a skin rash.

Chronic tonsillitis with enlargement and redness, but usually without pain, may cause malnutrition especially in children, and arthritis, rheumatic fever and other conditions in other parts of the body. Tonsillectomy is the accepted treatment for chronic tonsillitis. Unless the tonsils are greatly enlarged or are diseased they serve a purpose and should not be removed.

The adenoids are an accumulation of lymphoid tissue in the roof of the throat above and behind the palate. Enlarged adenoids occur usually in childhood, with nasal obstruction and mouth breathing, and obstruction of the Eustachian tubes with impaired hearing. Enlarged adenoids are one of the commonest causes of deafness in school children. The treatment is removal of the adenoids, usually done at the same time as removal of the tonsils.

Malignant disease (cancer) of the throat is not very common. It begins as a chronic swelling, at first painless, and later painful, and is diagnosed by removing a small piece of the suspicious tissue and examining it under the microscope. X-ray or radium treatment is often effective in controlling cancer of the throat.

Hoarseness is the symptom of disease of the larynx (voice box), and if the hoarseness lasts for more than two weeks the larynx should always be examined for a possible beginning cancer. Cancer of the larynx is one of the more common forms of cancer, and if discovered early it can be cured permanently in a high percentage of cases by removal of the tumour. Other causes for hoarseness are tuberculosis of the larynx, a benign tumour on the vocal cord called a "singer's node" because it comes from overuse of the voice and acute laryngitis from a sore throat, or from smoking. In children, severe hoarseness may be the first symptom of diphtheria of the larynx, known also as croup.

Early diagnosis and the use of antitoxin may save the life of a child with diphtheria of the larynx.

BIBLIOGRAPHY—Lawrence R. Boies, *Fundamentals of Otolaryngology* (1949) (G. E. S.)

EARL, a title and rank of nobility (corresponding to Lat. *comes*, Fr. *comte*), now the third in order of the British peerage, between marquis and viscount. Earl is the oldest title and rank of English nobles, and was the highest until 1337, when the Black Prince was created duke of Cornwall by Edward III.

The nature of a modern earldom is readily understood, since it is a rank and dignity of nobility which, while it confers no

official power or authority, is inalienable, indivisible, and descends in regular succession to all the heirs under the limitation in the grant until, on their failure, it becomes extinct.

The title is of Scandinavian origin, and first appears in England under Canute as *jarl*, which was Englished as *earl*. Like the *aldorman*, whose place he took, the *earl* was a great royal officer, who might be set over several counties, but who presided separately in the county court of each with the bishop of the diocese. Although there were counts in Normandy before the Norman Conquest, they differed in character from the English earls, and the earl's position appears to have been but slightly modified by the Conquest. He was still generally entitled to the "third penny" of the county, but his office tended, under Norman influence, to become an hereditary dignity and his sphere was restricted by the Conqueror to a single county. The right to the "third penny" is a question of some obscurity, but its possession seems to have been deemed the distinctive mark of an earl, while the girding with "the sword of the county" formed the essential feature in his creation or investiture, as it continued to do for centuries later. The fact that every earl was the earl of a particular county has been much obscured by the loose usage of early times, when the style adopted was sometimes that of the noble's surname (e.g., the Earls Ferrers), sometimes that of his chief seat (e.g., the Earls of Arundel), and sometimes that of the county. Palatine earldoms, or palatinates, were those which possessed *regalia*, i.e., special privileges delegated by the Crown. The two great examples, which dated from Norman times, were Chester and Durham, where the earl and the bishop respectively had their own courts and jurisdiction, and were almost petty sovereigns.

The earliest known charter creating an earl is that by which Stephen bestowed on Geoffrey de Mandeville, in or about 1140, the earldom of Essex as an hereditary dignity. Several other creations by Stephen and the empress Maud followed in quick succession. From at least the time of the Norman Conquest the earl had a double character, he was one of the "barons," or tenants in chief, in virtue of the fief he held of the Crown, as well as an earl in virtue of his "belting" (with the sword) and his "third penny" of the county. His fief would descend to the heirs of his body, and the earliest charters creating earldoms were granted with the same "limitation." The dignity might thus descend to a woman, and, in that case, like the territorial fief, it would be held by her husband, who might be summoned to parliament in right of it. The earldom of Warwick thus passed through several families till it was finally obtained, in 1449, by the Kingmaker, who had married the heiress of the former earls. But in the case of "co herresses" (more daughters than one), the king determined which, if any, should inherit the dignity.

The 14th century saw some changes introduced. The earldom of March, created in 1328, was the first that was not named from a county or its capital town. Under Edward III also an idea appears to have arisen that earldoms were connected with the tenure of lands, and in 1337 several fresh ones were created and large grants of lands made for their support. The first earldom granted with limitation to the male heirs of the grantee's body was that of Nottingham in 1383. Another innovation was the grant of the first earldom for life only in 1377. The girding with the sword was the only observance at a creation till the first year of Edward VI, when the imposition of the cap of dignity and a circlet of gold was added. Under James I the patent of creation was declared to be sufficient without any ceremony. An earl's robe of estate has three bars of ermine, but possibly it had originally four.

Something should be said of anomalous earldoms with Norman or Scottish styles. The Norman styles originated either under the Norman kings or at the time of the conquest of Normandy by the house of Lancaster. To the former period belonged that of Aumale, which successive fresh creations, under the Latinized form of "Albemarle" have perpetuated to the present day (see ALBEMARLE, WILLIAM DE FOSS). The so-called earls of Eu and of Mortain, in that period, were really holders of Norman *comtés*. Henry V and his son created five or six, it is said, but really seven at least, Norman countships or earls.

doms, of which Harcourt (1418), Perche (1419), Dreux (1427) and Mortain (1430) were below on English nobles, Eu (1419) and Tankerville (1419) on English commoners and Longueville (1419) on a foreigner, Gaston de Foix. Of these the earldom of Eu was assumed by the earls of Essex till the death of Robert, the parliament's general (1646), while the title of Tankerville still survives under a modern creation (1714). An anomalous royal licence of 1661 permitted the earl of Bath to use the title of earl of Corbeil by alleged hereditary right. Of Scottish earldoms recognized in the English parliament the most remarkable case is that of the Lords Umfraville, who were summoned for three generations (1297-1389) as earls of Angus, Henry, Lord Beaumont, also was summoned as earl of Buchan from 1334 to 1339.

The earldom of Chester is granted to the princes of Wales on their creation, and the Scottish earldom of Carrick is held by the eldest son of the sovereign under act of parliament.

The premier earldom is that of Arundel (99), but as this is at present united with the dukedom of Norfolk, the oldest earldom not merged in a higher title is that of Shrewsbury (1412), the next in seniority being Derby (1485) and Huntingdon (1529). These three have been known as "the catskin earls," a term of uncertain origin. The ancient earldom of Wiltshire (1397) was unsuccessfully claimed in 1869 by Scrope of Danby, and that of Norfolk (1312) in 1906 by Lord Mowbray and Stourton.

The premier earldom of Scotland as recognized by the Union Roll (1707) is that of Crawford, held by the Landsys since its creation in 1398, but it is not one of the ancient seven earldoms. The Decree of Ranking (1606) appears to have recognized the earldom of Sutherland as the most ancient in virtue of a charter of 1347, but the house of lords decision of 1771 recognized it as having descended from at least the year 1275, and it may be as old as 1218. It is at present united with the dukedom of Sutherland. The original seven earldoms (of which it was one) represented seven provinces each of which was under a *norman*. This Celtic title was rendered *earl* by the Norsemen and under Alexander I (c. 1115) began to be replaced by *earl* (*comes*), as a result of Anglo-Norman influence, which also tended to make these earldoms less official and more feudal.

In Ireland the duke of Leinster is, as earl of Kildare, premier earl as well as premier duke.

An earl is "Right Honourable," and is styled "My Lord." His eldest son bears his father's second title and, therefore, that second title being in most cases a viscountcy, he generally is styled "Viscount," where, as with Devon and Huntingdon, there is no second title, one may be assumed for convenience, under all circumstances, however, the eldest son of an earl takes precedence immediately after the viscounts. The younger sons of earls are "Honourable," but all the daughters are "Ladies." In formal documents and instruments, the sovereign, when addressing or making mention of any peer of the degree of an earl, usually designates him "trusty and well-beloved cousin"—a form of appellation first adopted by Henry IV, who either by descent or alliance was actually related to every earl and duke in the realm. The wife of an earl is a countess, she is "Right Honourable," and is styled "My Lady." For the earl's coronet see CROWN AND CROWNET.

See Lord, Reports on the Dignity of a Peer, Pike, Constitutional History of the House of Lords, Selden, Titles of Honour, G. E. (Cokayne), Complete Peerage, J. H. Round, Geoffrey de Mandeville (1892) (J. H. R.).

EARLE, JOHN (c. 1601-1665), English divine, was born at York about 1601. He matriculated at Christ Church, Oxford, but migrated to Merton, where he obtained a fellowship. In 1631 he was proctor and also chaplain to Philip, earl of Pembroke, then chancellor of the university, who presented him to the rectory of Bishopston in Wiltshire, and in 1641 he was appointed chaplain and tutor to Prince Charles. Early in 1643 he was chosen chancellor of the cathedral of Salisbury, but was soon deprived as a "malignant," and in the same year was elected one of the assembly of divines at Westminster but declined to sit. After Cromwell's victory at Worcester, Earle went abroad, and

was named clerk of the closet and chaplain to Charles II, being appointed dean of Westminster at the Restoration and in 1661 one of the commissioners for revising the liturgy. In Nov. 1662 he was consecrated bishop of Worcester, and was translated ten months later, to the see of Salisbury, where he conciliated the Non-conformists.

Earle was on friendly terms with Richard Baxter and was strongly opposed to the Conventicle and Five Mile acts. During the Great Plague Earle attended the king and queen at Oxford, and there he died on Nov. 17, 1665.

Earle wrote the witty work entitled *Microcosmographie, or a Pease of the World Discovered, in Essayes and Characters* (1628-33), which ran through ten editions in the author's lifetime. He was employed by Charles II to make the Latin translation of the *Eikon Basilike*, published in 1649, a similar translation of Hooker's *Ecclesiastical Polity* was accidentally destroyed.

See Philip Buss's edition of the *Microcosmographie* (1811 and 1868).

EARL MARSHAL, in England, ranks as the eighth of the great officers of state, is the head of the college of arms and up points the kings of arms, heralds and pursuivants. He attends the sovereign in opening and closing the session of parliament, walking at his or her right hand. He arranges state processions and ceremonies, especially coronations, royal marriages and funerals, and with the lord great chamberlain he assists in introducing newly created peers in the house of lords.

He exercised joint and co-ordinate jurisdiction with the constable in the court of chivalry, and afterward became the sole judge of that tribunal till its obsolescence in 1737. The marshalship of England was formerly believed to have been inherited from the Clives by the Marshal family, who had only been marshals of the household. It was held, however by the latter family as early as the days of Henry I, and passed to the Bigods. In 1306 it fell by inheritance to Edward I, and in 1316 was granted by Edward II to his own younger brother, Thomas "of Brotherton," earl of Norfolk. As yet the style of the office was only "marshal." The office, having reverted to the crown, was granted out anew by Richard II in 1385 to Thomas Mowbray, earl of Nottingham, the representative of Thomas "of Brotherton." In 1386 the style of "earl marshal" was formally granted to him in addition. After several attitudos and partial restorations in the reigns of the Tudors and the Stuarts, the earl marshalship was granted anew to the Howards by Charles II in 1672 and entailed on their male line, under which settlement it has regularly descended to the present duke of Norfolk. Its holders, however, could not execute the office until the Roman Catholic emancipation, and were forced to appoint deputies. His grace appends the letters "E.M." to his signature, and bears behind his shield two batons crossed in saltire, the marshal's rod (*virga*) having been the badge of the office from Norman times. There appear to have been hereditary marshals of Ireland, but their history is not well ascertained. The Keiths were great marshals of Scotland from at least the days of Robert Bruce, and were created earls marshal in or about 1458, but lost both eridom and office by the attainder of George, the 10th earl, in 1716. (See also MARSHAL.)

See "The Marshalship of England," in J. H. Round, *Commune of London and Other Studies* (1899), G. E. (Cokayne), *Complete Peerage* (J. H. R.).

EARLOM, RICHARD (1742-1822), English mezzotint engraver, was born and died in London. In 1765 he was employed by Alderman Boydell, then one of the most liberal promoters of the fine arts, to make a series of drawings from the pictures at Houghton Hall, and these he afterward engraved in mezzotint. His most perfect works as engraver are perhaps the fruit and flower pieces after the Dutch artists Van Os and Van Huysum. Earlom executed a series of 200 facsimiles of the drawings and sketches of Claude Lorraine, which was published in three volumes under the title of *Liber veritatis* (1777-1819).

EARLSTON (formerly ERICLIDOUNE, of which it is a corruption), civil parish, Berwickshire, Scot. Pop. (1951) 1,761. The village is on Leader Water in Lauderdale, 7½ mi. SE of Edinburgh by rail, and about 4 mi. NE of Melrose. Originally it was

called Arctoldun or "Prospect Fort," an ancient earthwork on Black Hill. In the 12th and 13th centuries the Lindsays and the earls of March and Dunbar were the chief baronial families. The ivy clad ruin of the ancient tower, "The Rhymer's Castle," is the traditional residence of Thomas Learmont, commonly called Thomas of Ercildoune, or Thomas the Rhymer, poet and prophet, and friend of the Fairies, who was born here about 1225. The Edinburgh Border Counties Association acquired this relic and surrounding lands in 1895. The leading manufactures are ginghams and tweeds, and the town is also an agricultural centre, stock and corn sales taking place at regular intervals and cattle and horse fairs being held every year. Some 3 mi. away is Bemersyde, which has been in the possession of the Haigs since probably the 12th century, and which was presented to Field Marshal Earl Haig by the nation in 1921. The prospect from Bemersyde Hill was Sir Walter Scott's favourite view. The castle at Bemersyde was erected in 1535 to secure the peace of the Border.

EARLY, JUBAL ANDERSON (1816-1894), American soldier and lawyer, was born in Franklin county (Va.), on Nov. 3, 1816, and graduated at West Point in 1837. He served in the Seminole War of 1837-38, after which he resigned in order to practise law in Franklin county, Virginia. He also engaged in State politics, and served in the Mexican War as a major of Virginia volunteers. He was strongly opposed to secession, but thought it his duty to conform to the action of his State. As a colonel in the Confederate army, he rendered conspicuous service at the first battle of Bull Run (*qv*). Promoted brigadier general and later major-general, Early served throughout the Virginia campaigns of 1862-63, and defended the lines of Fredericksburg during the battle of Chancellorsville. At Gettysburg he commanded a division of Ewell's corps. In the campaign of 1864, Early, who had now reached the rank of lieutenant general, commanded the Confederate forces in the Shenandoah valley. After several successful actions in the Shenandoah and Potomac valleys (on July 11 he threatened the city of Washington), Gen. Sheridan arrived with Union reinforcements, forced Early to retreat, and defeated him at Winchester and Fisher's Hill. Finally, on Oct. 19, after inflicting at first a severe blow upon the Federal army in its camp at Cedar creek, he was decisively beaten by Sheridan. (See SHENANDOAH VALLEY CAMPAIGNS.) Waynesboro (March 1865) was his last fight, after which he was relieved of his command.

Gen. Early was regarded by many as one of the ablest soldiers in the Confederate army.

After the declaration of peace he went to Canada, but in 1867 returned to resume the practice of law. For a time he managed the Louisiana lottery in conjunction with Gen. Beauregard. He died at Lynchburg (Va.), on March 2, 1894. Gen. Early was for a time president of the Southern Historical Society, and wrote, besides various essays and historical papers, *A Memoir of the Last Year of the War, etc.* (1867).

See *Lieutenant General Jubal Anderson Early, an Autobiographical Sketch and Narrative of the War Between the States* (1912).

EARLY CLOSING MOVEMENT The Early Closing Association came into existence in Great Britain following a meeting of drapers' assistants held at the Commercial Tavern, Holborn, on Oct. 1842. A resolution was then passed "that the present hours of business are longer than either the convenience or the necessities of the public require and that a judicious curtailment thereof may be effected, without injury to any of the principals concerned, which would be productive of the most beneficial results." In the period after 1842 great progress was made, including (1) the establishment of the Saturday half-holiday culminating in the Shops act, 1912, legalizing a weekly half-holiday for every shop assistant, (2) the Shops Seat act (1899), which stipulated for one seat to every three female assistants in shops, (3) the Shops act (1920), which provided compulsory closing of shops at eight o'clock weekday nights and nine o'clock Saturdays, in addition to the weekly half-holiday, and (4) improved shop conditions.

The Saturday half-holiday became a British national institution, and was adopted by almost every other country in the world.

(A. LK.)

United States—Laws limiting working hours of mercantile employees had been passed in most states prior to World War II, but actual openings and closings were determined by employers. Traditionally, Saturday became the chief shopping day of the week, with most stores remaining open later on that day, particularly in firm communities. After 1942, however, the changed buying habits of the public, resulting from increased income and population shifts into war industry areas, caused merchants to experiment radically with store hours.

The department stores in some of the large cities eliminated the late Saturday closing and substituted instead certain weekdays.

Chain grocery stores and butcher shops in many of the bigger cities also eliminated the late Saturday closing. In the food trade the early closing policy was initiated by the meat cutters' trade union in San Francisco before 1920, and thereafter was generally adopted in other western cities. Labour's desire for improved working conditions became an increasingly important factor during the seven years previous to 1940 which saw the passage of the National Industrial Recovery act, the Wagner act and the Fair Labor Standards act.

Early closing hours for department stores were first demanded by the Working Women's society in 1891. This group enlisted the support of women consumers to secure better conditions for store employees by constructive legislation.

After its inception in 1891, the Consumers' League of New York helped bring about a shortened week for women employees, improved working conditions in retail stores, the closing of stores in the evening, half holidays on Saturday, and advocated early Christmas shopping.

(R. GR.)

EARLY ENGLISH PERIOD, in architecture, the first of the three divisions into which the English Gothic style is usually divided. Although originally the term was applied to English Gothic up to the beginning of the 14th century (as by Rickman and R. P. Spers), it is now more customarily limited to the first half of the 13th century. In the last quarter of the 12th century, partly through the influence of the Cistercian order and partly through that of the French design of the early Gothic parts of Canterbury cathedral (choir, c. 1175-78), pointed arches and other Gothic ideas became more and more common, so that by the end of the century the transitional period was over and the architecture of England completely Gothic. It is this earliest developed Gothic which is known as Early English. The chief characteristics of the style are: frequent use of high, slim openings, capped with steeply pointed arches, known as lancets, often grouped in threes, hves (the "five sisters") in the transept of York cathedral) or even in sevens, simple four part church vaulting (see VAULT), often with a ridge rib in addition to groin, cross and wall ribs, arch mouldings, consisting of complex combinations of convex projections with deep, rounded hollows, nave and chapter house piers of a central core of stone surrounded by a number of black Purbeck marble shafts, tied together by occasional moulded bands, capitals, almost always consisting of a circular abacus with rich mouldings below, or sometimes with conventionalized foliage with many rounded lobes, frequent use of ball flower (*qv*) and dog-tooth (*qv*) ornament. Toward the end of the period the use of tracery became general, lavishness of ornament increased, as in the diaper patterns in the arch spandrels of Westminster Abbey, and naturalism in the carving grew. Outstanding examples of the style are Salisbury cathedral, begun 1220, the nave and transept of Wells cathedral, end of the 13th century to 1242, parts of York cathedral transepts, 1230-60. (See GOTHIC ARCHITECTURE.)

(T. F. H.)

EARN, a loch and river, Perthshire, Scotland. The loch is 6½ m. long east to west and ¾ m. in maximum breadth. It discharges by the river Earn. On its shores are Lochearnhead (at the southern extremity of Glen Ogle), which has a station on the railway from Perth to Balquhdder, and the ruins of St. Blane's chapel, Ednam Castle, an old towered mansion belonging to the marquess of Breadalbane, situated in well-wooded grounds near the pretty falls of the Ample, Ardvorlich House, the original of Dar

invarach in Scott's *Legend of Montrose*, and the village of St. Fillars at the foot of the loch. The river, a notable fishing stream, flows out of Loch Earn eastwards with a gentle inclination to wards the south, and reaches the Firth of Tay, 64 m below Perth. The principal places of interest on the banks of the Earn are Dunira House, the village of Comrie, the town of Crieff, the ruined castle of Innerpeffer, founded in 1610 by the 1st Lord Maderty, close to which is the library founded in 1691 by the 3rd Lord Maderty, containing some rare black letter books and the Bible that belonged to the marquess of Montrose, Gascon Hall, now in ruins, but with traditions reaching back to the days of Wallace, Duppelin Castle, a fine mansion in Tudor style, Forgan denny, and Bridge of Earn, a health resort situated amidst picturesque surroundings. Strathearn, as the valley of the Earn is called, extending from the loch to the Firth of Tay, is a beautiful and, on the whole, fertile tract, though liable at times to heavy floods. The earl of Perth is hereditary steward of Strathearn.

EARNEST, the payment of a sum of money by the buyer of goods to the seller on the conclusion of a bargain as a pledge for its due performance. It is almost similar to the *arrha* of the Roman law. Apart from its survival as a custom, its chief importance in English law is its recognition by the Statute of Frauds as giving validity to contracts for the sale of goods of a value exceeding £10. (See *SALE OF GOODS*) It is in that statute clearly distinguished from part payment, consequently any sum, however small, would be sufficient as earnest, being given as a token that the contract is binding and should be expressly stated so by the giver. (See *DEPOSIT*)

EAR-RING, an ornament worn pendent from the ear, and generally suspended (especially among the more civilized races) by means of a ring or hook passing through the pendulous lobe of the ear. Among savage races the impulse to decorate, or at any rate to modify the appearance of the ear, is almost universal. The Berawan people of Borneo use plugs through the lobe of the ear $\frac{3}{4}$ in in diameter. More extraordinary still is an example of a stone ear plug worn by a Masai, $\frac{1}{2}$ in in diameter and weighing 2 lb 14 ounces. Among the superior races, though ear ornaments of extravagant size and elaboration are not unknown, moderation in size is commonly observed, and greater attention is paid to workmanship and fineness of material.

The general usage appears to have been to have ear rings worn in pairs, the two ornaments in all respects resembling each other, in ancient times, or more recently among Oriental races, a single ear-ring has sometimes been worn. The use of this kind of ornament, which constantly was of great value, dates from the remotest historical antiquity, the earliest mention of ear-rings occurring in the book of Genesis. It appears probable that the ear-rings of Jacob's family, which he buried with his strange idols at Bethel, were regarded as amulets or talismans, such unquestionably being the estimation in which some ornaments of this class have been held from a very early period as they still are held in the East. Thus in New Zealand ear-rings are decorated with the teeth of enemies, and with talismanic sharks' teeth. Among all the Oriental races of whom we have any accurate knowledge, the Hebrews and Egyptians excepted ear-rings always have been in general use by both sexes, as general in the West, as well as by the Hebrews and Egyptians, as a general rule they have been considered exclusively female ornaments. By the Greeks and Romans also ear-rings were worn only by women, and the wearing of them by a man is often spoken of as distinctly oriental.

In archaic art ear-rings are frequently represented or their traces are left in the perforated ear lobes of early statues. After

the 4th century such perforations occur seldom. In one instance, a Greek inscription records the weight of the detachable gold ornaments on a statue, among which a pair of ear-rings is included. Ear-rings of characteristic form are frequently discovered by excavation. In Egypt, a system of pendent chains is found hanging from a disc. In Assyria the decoration consists of pendants or knobs attached to a rigid ring. In the Mycenaean period, ear-rings are infrequent in Greece, but have been found in abundance in the Mycenaean finds of Enkomi (Cyprus) in the form of pendent bulls' heads, or of decorative forms based on the bull's head. In the tombs of the Greek settlers in the Crimea (4th century a.c.), ear-rings are found of marvellous complexity and beauty. The lexicographer Pollux, speaking of the names given to ear-rings, derived from their forms, mentions caryatids, hippo camps and centauresses. Jewels of the same class, of exquisite beauty and of workmanship that is truly wonderful, have been rescued from the sepulchres of ancient Etruria. Ear-rings of comparatively simple forms, but set with pearls and other stones, were the mode in Rome. Researches among the burial places of Anglo-Saxon Britain have led to the discovery of jewels in considerable numbers, which among their varieties include ear-rings. These ornaments, which have never fallen into disuse, showed a considerable decline in Europe and America during the 19th century, but have been revived again in the 20th century to the extent that they are not uncommonly worn on the street or with evening dress. The more recent ones do not pierce the ear and are considerably smaller. (See also *JEWELLERY*)

EAR-SHELL see *ABALONE*

EARTH In the present article we shall treat the subject matter of the earth as a planet under the following headings—(1) size, mass, density and form, (2) movements, (3) constitution, (4) age of the earth, and (5) earth's thermal history.

SIZE, MASS, DENSITY AND FORM

To primitive man the earth was a flat disk with its surface diversified by mountains, rivers and seas. The spherical form was ascribed by Pythagoras, and Aristotle used arguments in its favour similar to those used to day, viz., the ship gradually dis-

A BANTU NEGROID

Among certain African tribes ear-rings are worn not so much for ornament as for pulling the ear into a fashionable size and shape.

FIG. 1.—DIAGRAMMATIC SECTION OF EARTH THROUGH POLAR AXIS TO ILLUSTRATE LATITUDE.

The latitude of a point P is the angle λ between PN parallel to the polar axis and a horizontal plane through P. The zenith distance of the pole is the angle $\angle NPZ = 90^\circ - \lambda$. QX and RY are normals to the polar axis and the difference between CQ and RA represents the difference in length of a degree of latitude near the pole and near the equator.

appearing, hull first, masts later, as it recedes beyond the horizon, the circular shadow cast on the moon during an eclipse, and the alteration in the appearance of the heavens as one passes from place to place on the surface. With regard to the last point, we may notice that if the earth were flat any star above it would be visible from every point of it. This is not true: many of the stars visible in England are never visible in South Africa or Australia, and conversely. On the other hand, an observer on the surface of a spherical earth would see every star that is above the tangent plane to the sphere at the point where he is. The direc-

tion of this plane varies with his position, and therefore the stars visible also depend on his position. The mean altitude (angular elevation above the horizon) of the Pole star is equal to the latitude of the place, for observers in the northern hemisphere.

The spherical form did not, however, become generally believed until after explorers had actually sailed around the earth, though this argument is not intrinsically so conclusive as any of the three first given. The distance a traveller has to proceed northwards to make the mean altitude of the Pole star increase by 1° is a "degree of latitude." Eratosthenes, in 250 B.C., was the first to measure this, by determining the difference of latitude between Alexandria and Syene, but there is some doubt about his measurement of the distance between these places. Jean Picard, in 1671, obtained the first useful estimate. From the length of the degree of latitude the size of the earth can be calculated.

Actually, the length of the degree of latitude is found to vary slightly with latitude. This is because the earth is not exactly a sphere, a better approximation to its shape being an oblate spheroid (the surface swept out by an ellipse rotated about its shortest diameter). Such a surface is flatter near the pole than near the equator, and the degree of latitude is therefore longer in high latitudes than in low ones. This observation of the length of the degree in both high and low latitudes determines both the size of the earth and its polar flattening. The best determination yet made is that of J. F. Hayford, from observations in the United States, published in 1910. He gives

$$\begin{aligned} a &= \text{equatorial semi axis} = 6,378.388 \text{ km} \\ b &= \text{polar semi axis} = 6,356.909 \text{ km} \\ \frac{a-b}{a} &= \text{ellipticity} = \frac{1}{297.0 \pm 0.5} \end{aligned} \quad \pm 0.18 \text{ km}$$

The distance from pole to equator, measured along the surface, is very nearly 10,000 kilometres.

The mass of the earth is found by comparing its gravitational attraction on a small sphere at its surface with that of a large sphere of known mass on the same small sphere. The attractive force satisfies the law of gravitation, namely, that the force pro-

duced on a given small body is proportional to $\frac{m}{r^2}$, where m is the

mass of the attracting body and r the distance of its centre. If then the forces produced and the distances are known, we can find the ratio of the masses. Observations by C. V. Boys and P. R. Heyl give the mass to be $(5.976 \pm 0.005) \times 10^{21}$ metric tons (1 metric ton = 10^3 grams = 0.9842 British ton). This is the mass of a body with a volume equal to that of the earth, and with a density equal to 5.517 ± 0.004 times that of water. The mean density of the earth is therefore 5.517 gm per cc .

Movements

The motion of the earth is known if we know three things which are independent or nearly so: first, the motion of its centre, second, its rotation about its centre, third, any variations of shape that may be taking place. These three types of motion may be described separately.

Movement of the Earth as a Whole—The most important part of the movement of the centre is the revolution about the sun. The centre of mass of the earth and moon together describes in the course of a year an elliptic path, with the centre of the sun at one focus. The mean distance from the sun is 149,700,000 km, or 92,900,000 miles. The eccentricity of the orbit is 0.016751 (eccentricity = difference of greatest and least distances \div sum of greatest and least distances).

The centre of the sun, however, is not fixed, but shares in the general motion of the solar system relative to the stars. The latter is a steady motion of the centre of mass of the whole system with a velocity of about 20 km per sec relative to the stars in its neighbourhood toward a point in the constellation Hercules. It is found by statistical discussion of the apparent motions of stars. The sun's centre is close to the centre of mass of the solar system, but moves with regard to it on account of the attractive forces of the planets on the sun. The planets also

attract the earth and moon. These forces introduce very complicated minor disturbances called perturbations.

The centre of mass of the earth and moon is about 4,800 km from the centre of the earth, the latter now is about the former in the course of a month on account of the attraction of the moon on the earth, and on this account the earth gets alternately in front of and behind its mean position. This monthly inequality provides a means of determining the moon's mass.

Rotation—The rotation of the earth about its polar axis is nearly uniform, the period being the sidereal day, which is 23 hr 56 min 4.095 sec of solar time. The revolution about the sun and the rotation were both established by Copernicus in 1543. In his great work *De orbium coelestium revolutionibus* it was shown that the common astronomical phenomena, such as the rising and setting of stars and the sun, the difference between the lengths of the sidereal and solar days, and the seasons, could be explained most simply by regarding the earth as revolving annually about a fixed sun, while rotating about an axis in itself. Later, the explanation of the revolutions of the planets was the greatest triumph of Newton's law of gravitation.

The position of the axis, however, varies. The disturbances are known as precession, nutation and the variation of latitude. Precession (often called precession of the equinoxes) is a motion of the earth's axis in a cone whose axis is perpendicular to the plane of the earth's orbit, so that the celestial pole appears to move in a circle about the pole of the ecliptic. The time taken for the complete revolution is about 25,800 years. The phenomenon was discovered by Hipparchus (120 B.C.), and was first explained by Newton. The attraction of the sun and moon on the earth's equatorial protuberance tends to make it move so as to bring the equator into the plane of the orbit of the earth or the moon respectively. But the earth's rotation introduces a gyroscopic control, and the ultimate result is that each point of the earth's axis moves parallel to the plane of its orbit. The explanation is similar to that of the motion of the axis of a spinning top. Gravity tends to make the axis move downward, but the spin of the top converts the disturbance into a revolution of the axis about the vertical. One effect of precession is that the equinoxes move around the ecliptic so as to be always moving to meet the sun. The rate is $50''$ 26 per year, enough to displace the equinoxes by 30° in 2,150 years. The vernal equinox, the point where the sun crosses the equator on its way north, is known in astronomy as the "first point of Aries", but of account of precession it is now in Pisces. Also 4,000 years ago the star nearest the pole was α Draconis, but since the pole has moved it is now α Ursae Minoris, in 12,000 years it will be Vega.

The force tending to alter the tilt of the axis is not constant, when the sun or moon is crossing the equator, for instance, it has no effect. The path of the pole is therefore not described with uniform velocity, and is not quite a circle. The departures from the uniform circular motion are called "nutations." The largest of them, discovered by Bradley, is the lunar nutation, with a period of 18.6 years and an amplitude of $9''$ 2 in latitude. This arises because the plane of the moon's orbit revolves on the plane of the ecliptic in 18.6 years, so that the motion of the pole caused by the moon is not always about quite the same point of the sky. The variation of latitude consists of two small movements, one with a period of about 14 months, the other of a year. Both have amplitudes of about $0''$ 1. The existence of the former was predicted on dynamical grounds by Euler, it is a circular oscillation of the axis akin to the wobbling of a badly thrown quill. If the earth were quite rigid its period would be 306 days, actually it is 439 ± 6 days, the difference being due to the earth's elastic yielding. The annual movement is due to seasonal displacements of matter over the earth's surface. Both were discovered by Chandler in 1841, the qualitative explanation is due to Newcomb.

Deformations—In addition to the above general movements, the earth is continually altering its shape. The movements involved in mountain formation and isostatic compensation are large but slow, taking millions of years for completion. The movement in a large earthquake may reach several metres close to the origin, it starts suddenly and is soon over, but elastic waves

are sent throughout the earth and produce small movements of the ground at great distances. The tidal forces of the sun and moon not only displace the water on the surface, but pull the solid earth itself somewhat out of shape; this deformation is associated with an indirect one due to the weight of the displaced oceanic waters. All of these movements require either long interval or sensitive instruments to make them perceptible.

CONSTITUTION

There are several different sources of information available concerning the constitution of the earth. Starting with the geological evidence, we know that most of the land surface is covered with a layer of sedimentary rocks. The chief of these are sandstones and shales, produced mainly by the weathering of granite and re-lit rocks and redeposition of the resulting sediments in shallow water. In addition, large areas within the continents are covered with ancient rocks akin to granite, and granite is also a common intrusive rock. For all these reasons geologists (following Suess) have come to believe in a widespread granitic layer under all the continents. Another very common intrusive rock is basalt, which exists in several different forms, such as dolerite, gabbro, eclogite and tachylyte. It is denser, in its commonest forms, than granite (1.3 against 2.7), and therefore has probably come from a greater depth. But the mean density of the earth is 5.5, nearly twice the density of basalt, and it has been shown that the high pressures in the interior of the earth are insufficient to compress basalt to such an extent. There must be much denser matter within the earth, and its density must be much greater than 5.5 to make up for the lighter stuff on the outside. This indicates an interior composed of heavy metals, especially iron, since this is the commonest heavy metal in the crust.

Upper Layers—More detailed information is provided by seismology. As has just been mentioned, earthquakes send out elastic waves through the body of the earth, and the arrival of these at distant stations is recorded by instruments. Two types of bodily waves exist in a solid: first, a compressional wave like a sound wave, such that, as the wave passes, a particle vibrates in the direction of travel of the wave, and second, a distortional wave, where the vibrating particle moves at right angles to the direction of travel of the wave. The two types are referred to for brevity, as *P* and *S*. The letters stand for "primary" and "secondary" because the compressional wave travels faster. The velocities depend on the elastic properties of the material (compressibility and rigidity, or resistance to change of shape) and on its density. When the substance is not uniform the energy of each wave behaves very much like that of light: that is, it travels in rays which are curved in such a way that the wave travels from one end of the ray to the other in a shorter time than it would take if it travelled by any slightly different path. As in the case of light, again, if there is a sharp boundary between two different materials, a wave reaching the boundary is partly transmitted and partly reflected. A complication arises, however, in elastic waves, in a solid, four waves arise at a boundary, a compressional one and a distortional one in each medium. The distortional wave is entirely characteristic of solids: it does not exist in a liquid.

It is actually found, when the times of arrival of the waves from a near earthquake at different distances are compared, that a pair of waves can be traced, travelling with velocities of 5.6 km per sec. and 3.5 km per sec. respectively. The former velocity agrees with that found by L. H. Adams and L. D. Williamson, of the Geophysical Laboratory at Washington, for the velocity of compressional waves in granite, possibly with some admixture of the glassy form obsidian. This wave is consequently denoted by *P*_g and the other, which appears to be the corresponding distortional wave, by *S*_g. They travel wholly in the granitic layer from the origin to the observing station, apart from their short passage upward through the sedimentary layer. These waves were first observed by A. Mohorovičić of Zagreb, Yugoslavia, in 1900.

If, however, a basalt layer underlies the granitic one it would be expected that some part of the waves sent out would be transmitted into this layer, travel through it, and be refracted up again

when they return to the boundary. Now actually not one, but two other pairs of waves can be traced, they have been given specific symbols, and their average velocities are *P*_g, 6.3 km per sec., *S*_g, 3.7 km per sec., *P*_g (or simply *P*) 7.8 km per sec., *S*_g (or simply *S*), 4.3 km per second. They have slightly different values in different regions. The curious fact is that none of these velocities fits that for compressional waves in crystalline basalt, as found in the laboratory, which is 6.9 km per second. The in-

FIG 2—PATHS OF THE SIX PULSES OBSERVED IN NEAR EARTHQUAKES aa sedimentary layer bb granitic layer cc intermediate layer dd dunite base

ference is that there is no widespread layer of crystalline basalt. The velocity of *P*_g fits either tachylyte, which is basalt in a vitreous, or glassy, condition, or diorite, a crystalline rock intermediate in composition between granite and basalt. *P*_g has a very high velocity. One rock that transmits waves with so high a velocity is dunite, a fire rock at the surface, but consisting almost entirely of the mineral olivine (Mg₂SiO₄ and Fe₂SiO₄), which is common as a constituent of mixed rocks. Eclogite, which has a similar composition to basalt, but a density of 3.3, gives a similar velocity. There are thus two possible successions with increasing depth, both consistent with the seismological data, namely, granite tachylyte dunite and granite diorite eclogite dunite. The former was suggested by H. Jeffreys, the latter by Professor A. Holmes, and both views have arguments in their favour. The six waves all appear to travel with uniform velocity, so long as the distance does not exceed about 900 kilometres. But their times of arrival are related as if they had started at times differing by a few seconds. If Δ is the distance of an observing station from the "epicentre" (the point of the surface vertically above the origin), T the time of arrival at the station, and v the velocity of travel of the wave, we have

$$T = T_0 + \frac{\Delta}{v}$$

where T_0 is the same for all stations for the same wave, so that the wave appears to have started at time T_0 and travelled out with velocity v . But every wave has its own T_0 , on account of the delay of the indirect waves in travelling down to the intermediate and lower layers, whereas the waves *S*_g and *P*_g come practically directly, just as walking to the next village may be quicker than travelling by train if one does not live near the station. These apparent delays in starting provide means of estimating the thicknesses of the granitic and intermediate layers, which are together about 30 km, under average continental conditions.

Below the ocean the structure must be somewhat different. Granitic rocks appear not to exist there, and basalt may come right up to the ocean bottom. On the other hand Holmes has suggested that there may be a thin upper layer of syenite, a rock resembling granite except that it contains no quartz. Direct seismological evidence is lacking, except that *P*_g and *S*_g seem to have the same velocities as under the continents. The chief difference between continents and oceans is, then, that under the oceans the granitic layer is absent or very thin.

Deeper Portions—At distances over 900 km the four waves *P*_g, *P*_g, *S*_g, *S*_g have all disappeared or at least become unrecognizable. But *P*_g and *S*_g still exist. Their observed times of transmission give a means of finding their velocities of propagation at great depths, which has been employed by E. Wiechert, B. Gutenberg, S. Mohorovičić and others. The velocities increase with depth, somewhat irregularly, to a depth of 0.45 of the radius, or 2,900 km, that of *P* varies within this range from 7.8 to 13.6 km per sec., the corresponding values for *S* are 4.35 km per sec. and

7.3 km per second. The increase is to be attributed mainly to an effect of the high pressure in increasing the stiffness of the material. The velocities increase rather sharply by about 10% at a depth of about 450 km.

P waves just reaching a depth of 2,900 km emerge at an angular distance of 103° from the epicentre, that is, the line joining the epicentre to the point of emergence subtends an angle of 103° at the centre of the earth. At greater distances, *P* and *S* cannot be detected. *P* reappears at a distance of 143° , and can be traced from there to the antipodes, but *S* never reappears at all. This is what would be expected if the earth had a liquid central core, for the fundamental property of a liquid is its inability to transmit distortional waves. But other alternatives are just possible, and we cannot decide that the central core is liquid without discussing other evidence.

P waves travel more slowly in the central core than just outside it, their mean velocity being about 9 km per second. These waves were first identified by R. D. Oldham in 1906, and further work on them has been done by Gutenberg and H. H. Turner. They emerge at minimum deviation at an angular distance of about 143° , and consequently have large amplitudes there. Between 105° and 143° only very small waves are recognizable, but there appears to be reflexion from a further discontinuity deep in the core. In addition, *P* and *S* waves incident on the central core are partly reflected and partly transmitted into the core as *P* waves. The reflected ones give the most accurate estimate of the radius of the core, which is 3473 ± 3 km. The transmitted wave derived from *S* is again broken up when it returns to the boundary, giving three parts, denoted briefly by *SAS*, *SKP* and *SKKS*. The first two re-enter the outer shell when the wave has passed through the core, the three letters in each symbol indicate the type of the wave in the three parts of its path, waves in the core being denoted by *K*. The third wave is reflected on the inside of the core, and emerges after describing another path in the core as *P* and being transmitted into the shell as *S*. The existence of all these waves was predicted by Gutenberg, who calculated their theoretical times of transmission from the known velocities of *P* and *S* at various depths, and they have all been found by observation at the predicted times by Gutenberg himself and other workers, especially Prof. H. H. Turner. The waves reflected at the inside and outside of the core are interesting because reflexion would not occur if the transition was gradual, they point to a sharp boundary between two quite different materials.

Deep Foci—It was inferred by Turner and confirmed by R. Stoney and F. J. Searle that some earthquakes occur at great depths, some are as deep as 600 km. They are important partly because they show that material so deep is still in such a state that it can undergo fracture, partly because certain additional reflexions in them give further information about the thicknesses of the upper layers.

Density at Various Depths—We have already seen that the high mean density of the earth also points to a difference of density between the interior and the exterior, comparable with that between metallic iron and ordinary rocks. There is reason to believe that the earth was once fluid, and in this state iron and silicates would not mix, thus a metallic core, sharply separated from a rocky shell, would be expected to exist. A correspondingly sharp change in properties with depth has been inferred, on entirely different evidence, from seismology. Seismology also indicates that there is no other large and sudden change. Hence we naturally infer that the two sudden transitions are identical, and that the thick outer shell, down to a depth of 2,900 km, is composed of a silicate rock resembling olivine in composition, while the central core below that depth is made of metallic iron, probably in the liquid state. The change of velocity about 450 km down is found by K. E. Bullen to be associated with a rise of density of 0.5, which J. D. Bernal interprets as due to a change of crystal form of olivine under high pressure.

The theory of the figure of the earth leads to another datum, involving the earth's "moments of inertia." The moment of inertia of a body about a line is obtained by multiplying the mass of every particle of the body by the square of its distance from the

line, and adding up for all the particles. The moment of inertia of the earth about the polar axis is denoted by *C*, and that about any diameter in the plane of the equator is denoted by *A*. *C* is greater than *A* because the earth is spheroidal, particles, on an average, are farther from the polar axis than from one in the equatorial plane. Now the rate of precession contains as a factor the ratio $\frac{C-A}{C}$, which is therefore sometimes called the

"precessional constant" or the "dynamical ellipticity." This rate being observed, and every other factor in the formula for it being known, we can therefore find the precessional constant,

which is $\frac{1}{305.6}$. But $C-A$ can also be found absolutely, because it is the only unknown in the formula for the variation of gravity over the surface of the earth and certain perturbations of the moon. Hence *C* can be found by simple division. It is conveniently expressed by the equation

$$\frac{C}{Ma^2} = 0.334$$

where *M* is the earth's mass and *a* its equatorial radius. If the earth was a uniform sphere this ratio would have been 0.400, the difference gives new evidence that the earth is much denser near the centre.

Every layer in the earth is compressed by the weight of the matter above it, but the compressibility can be inferred from the velocities of seismic waves. Bullen finds that the density must increase from about 3.3 to 3.7 between 30 and 450 km of depth, rising there to 4.2 and reaching 5.5 at the core boundary. In the core it increases from 9.9 to at least 12.2.

The density of dunite is near the mean density of the moon, for which the effect of compression is small.

The Bodily Tide—The density and the velocities of propagation of the *P* and *S* waves at any depth being by this time fairly accurately known, the elastic constants (the incompressibility and the rigidity) of the matter can be found. Hence it becomes,

FIG. 3.—PATHS OF PRINCIPAL PULSES OBSERVED IN DISTANT EARTHQUAKES. THOSE STARTING AS *P* ARE SHOWN ON THE LEFT. THOSE STARTING AS *S* ON THE RIGHT.

theoretically, possible to calculate how the earth as a whole would yield under known forces. The 14-monthly variation of latitude and the tides both provide data capable of being compared with theory. If the earth were perfectly rigid, the period of the variation of latitude would be 306 days, if it were a fluid, the variation of latitude would not exist. If, again, the earth were fluid, the interior would yield so much to tidal forces that the ocean could

yield no more, and there would be no visible tides. The actual tides are about 0.7 as high as they would be on a rigid earth. The two sources of information are closely related, but do actually give distinct checks on any theory. Lord Kelvin showed that the tidal yielding of the solid earth was no more than that of a globe of steel of the same size. We know now, however, that the dunite at a depth of 30-40 km is about two thirds as stiff as steel, and the matter 2,900 km down is fully twice as stiff as steel. If the central core were equally stiff, it can be shown that the earth as a whole would yield less than tides and the variation of latitude show it does. It has not yet been definitely shown that a liquid central core would give complete agreement, but it would certainly fit the facts much better than any reasonable hypothesis consistent with the solidity of the core.

Summary—The structure of the earth, along a radius emerging at a typical point within a continent, would be as follows—

	Thickness (km)	Density
Sedimentary layer	0-5 (?)	2-2.7
Granitic layer	18 ± 3	2.7
Tachylite or diorite layer	15 ± 4	2.9-3.0
Dunite shell (possibly with eclogite near the top)	2,900	3.3 (top) 5.5 (bottom)
Liquid iron core	3,500	9-12

In oceanic regions the granitic layer may be absent, the sedimentary thin and formed of deep sea deposits, and the tachylite one replaced by matter of similar composition, but crystalline. The thicker shell and the central core are much the same below sea as below land.

THE AGE OF THE EARTH

On almost any theory of the origin of the earth it was originally fluid, probably gaseous. (See COSMOGONY.) The primitive earth would likely partly through loss of heat by radiation from the outside and partly by adiabatic expansion. The latter leads to the formation of liquid drops as in a liquid air machine, and the drops would gradually collect towards the centre. The formation of a liquid earth, probably with an atmosphere of some of its more volatile constituents, would be a matter of centuries. Further cooling would lead to solidification, the time needed for this would be longer on account of the reduced temperature and dissipation, but in a few thousand years at most the earth would have a thick solid shell on the outside. The further time taken for the outer surface to cool down, until its temperature was maintained almost wholly by the sun's radiation, would be only a few years. The temperature would then be near the present temperature, since the sun was in nearly its present state. The moon must be almost as old as the earth. Thus the intervals that have elapsed since the earth separated from the sun, since the moon was formed, or since the earth's outer surface became approximately as cool as it is now, do not differ by more than a few thousand years.

Denudation—As soon as the outer surface became cool, an ocean could form—though possibly only a small one at first—and rain and rivers, denudation and sedimentary rocks came into existence. Several methods are available for estimating the age of the earth, but they are not all of equal accuracy or reliability. The simplest, apparently, is that based on denudation. If we know the total mass of sedimentary rocks over the earth's surface, and the annual amount of sediments carried to the sea by rivers, a simple division gives an estimate of how long the process has been going on. The transport of sediments to the sea by rivers, together with the present total amount of salt in the sea, gives another estimate. Both methods suggest ages of about 300,000,000 years. But it is important to notice that many factors can vitiate both. In particular, purely geological evidence makes it clear that the present rate of denudation is considerably in excess of the average of the past, owing to the existence of many high and comparatively new mountain ranges and the large amount of easily denuded matter left by the last glacial period. These methods can, therefore, at most suggest an order of magnitude.

Kelvin's Arguments—Two methods were given by Lord

Kelvin, one based on the rate of supply of energy from the sun, and the other on the cooling of the earth's crust by conduction. In the former he supposed, following Helmholtz, that the sun's energy was maintained by contraction, and found that the whole energy liberated by the sun, in contracting from an infinite distension to its present size, would maintain radiation, at the present rate, for only about 20,000,000 years. In the latter he considered the cooling of the earth from the state just after solidification, and found how the rate of increase of temperature with depth in the crust depended on the time the earth has been cooling. This increase of temperature with depth is known by observation. The method, with modern data, gives about 27,000,000 years for the age of the earth.

There is now an overwhelming amount of evidence that the earth and the sun are both very much older than Kelvin's results would indicate. Yet the value of his attempts has not disappeared. Numerous astronomical sources of information have shown that the sun has been radiating as vigorously as now for thousands of millions of years, and not merely for tens of millions, and we must infer that stars can draw on some source of energy much more provident than contraction under gravity. This is probably the transformation of hydrogen into helium. A mechanism for this has been investigated by H. A. Bethe.

Radioactivity—The argument from the earth's thermal state was shown to require modification by the discovery of radioactivity. It was found that all surface rocks contained minute quantities of radioactive elements, and they were enough to indicate the probability that a large fraction of the heat being conducted out of the earth is of radioactive origin and does not arise from the original heat. But if so the original heat accounts for a smaller rate of increase of temperature with depth than was previously thought, in other words, cooling has proceeded to a greater depth and the time taken has been longer than Kelvin's theory indicates. Nevertheless, his theory is not done with. The earth is not so old that original heat has ceased to be important, and Kelvin's work shows how to estimate its importance. Its geo-physical interest will not disappear till after the hot central core freezes.

Radioactivity not only showed the need of supplementing the old theory, but provided a new means of determining geological time, and this method is the best that is known. Radioactivity consists in the breaking up of elements with high atomic weights, in all known cases the disruption takes place by the loss of an α -particle, which is a charged helium atom, or by the loss of a β -particle, which is a free electron. In each case a certain amount of radiative energy is also liberated. The atomic weight of uranium is 238, that of helium is 4. Thus when an α particle is lost the atomic weight decreases by 4, when a β -particle is lost it decreases by an insignificant amount. The products of the decay of uranium have therefore atomic weights of 234, 230, 226, 222, 218, 214, 210 and 206, but several may have nearly the same atomic weight owing to loss of β -particles. The most interesting of the products, for our purpose, are those with atomic weights 226 and 206, namely, radium and lead. Radium breaks up at a known rate, in a given sample of radium 1 part in 2,280 breaks up every year. But in spite of its short life, radium is present in all uranium minerals, in a constant proportion corresponding to 36 atoms of radium per hundred million of uranium. The explanation is that uranium itself breaks up at such a rate as to replenish the radium as fast as this in its turn breaks up. For this to be possible one atom of uranium in 6,400,000,000 must break up every year.

The final product is a kind of lead, that is to say, no chemical test will distinguish it from ordinary lead, but its atomic weight is 206 instead of 207.2. Lead is always found in uranium minerals, and when it was isolated it was actually found to have atomic weight 206. The different kinds of lead were the first examples discovered of *isotopes*, elements identical in chemical behaviour but differing in atomic weight, but numerous others are known through the work of Aston.

Now, this lead is being produced from uranium at a known rate: for every 6,400,000,000 atoms of uranium 1 atom of lead is

produced every year, or, if we allow for the difference in atomic weights, 7,400,000 parts by weight of uranium produce 1 part by weight of lead every year. Hence if a mineral contained no lead to begin with, and now contains x parts of lead to 1 of uranium, the age of the mineral is 7,400 million years. Petrologists can recognize when original lead must have been absent, and the method is therefore applicable to the determination of the ages of minerals, and hence to the absolute measurement of geological time. The element thorium behaves somewhat similarly to uranium, its final product being a lead of atomic weight 208. When uranium and lead are both present in a mineral the age can be calculated by the approximate formula of Holmes and Lawson —

$$\text{Age} = \frac{\text{Pb}}{\text{U} + 0.38\text{Th}} \times 7,400,000,000 \text{ years}$$

Holmes and Lawson give also a slightly more accurate formula, allowing for the variation of the amounts of uranium and thorium with time. The oldest known minerals to which this method is applicable have been found to have ages of about 1,800,000,000 years. The coal measures were laid down about 250,000,000 years ago. The former estimate is therefore a minimum estimate of the age of the earth.

The radioactive elements can be applied in another way, due to H. N. Russell, to find an upper limit to the age of the earth. The above method is based on the analysis of minerals specially rich in uranium and thorium. But these elements are present in all rocks, and the method could be applied to the earth's crust as a whole. A caution necessary is that some of the lead may have always been lead and not have been produced by radioactivity during the geological time. Consequently the method gives an upper limit. The amounts of the relevant elements, in parts by weight, shown by averages of analyses of rocks, are U, 6 parts per million, Th, 15 parts per million, Pb, 7.5 parts per million. The quantity of lead is too small to be consistent with the existence of the earth for more than about 3,000,000,000 years, according to Holmes's latest revision. Thus radioactivity leads to the conclusion that the age of the earth is between 1,800,000,000 and 3,000,000,000 years.

Evidence from Cosmogony *The Orbit of Mercury*—Two arguments from cosmogony also give evidence concerning the age of the earth. The first is based on the fact that planets formed by ejection from the sun would move originally in very elongated orbits, which must have been altered to their present circular form by some later influence. The only cause known that could produce such an effect is the resistance of the gaseous medium surrounding the sun, formed of the parts of the primitive filament that failed to condense into planets. The medium would meanwhile degenerate gradually on account of viscosity and diffusion. The time such a medium would take to reduce the eccentricity of the orbit of Mercury to its present value is inversely proportional to its density, the time it would take to become destroyed by viscosity and diffusion is directly proportional to its density. These times must be somewhere near equal, because, if the medium was not dense enough to begin with, it would have disappeared before it had produced its actual effect, while if it was too dense a large amount of it would still remain and would be visible. From a comparison of the two intervals of time it is found that the age must be of the order of magnitude of 3,000,000,000 years. Great accuracy is not possible.

Tidal Friction—An alternative method depends on the history of the earth and moon. The rotation of the earth is not absolutely uniform, the day is becoming longer by about one second in 120,000 years. The change affects the observed times of ancient eclipses to a measurable extent, and it is from these that the amount is determined. The explanation depends on the tides produced by the sun and moon. The tidal currents in shallow seas are resisted by friction over the bottom, and this leads to a certain amount of dissipation of energy and to a reaction on the tides in mid ocean, giving a systematic disturbance of the times of high water. If no friction took place the attraction of either the sun or the moon on the tides raised by itself would act exactly through

the centre of the earth, and would have no tendency to turn it, but the displacement of the times of high water causes the attraction to act along a line passing a little to one side of the centre, and consequently to alter the rotation of the earth. A reaction on the moon makes the moon go farther off, and explains how the moon can have receded to its present distance from its probable original close proximity to the earth's surface. The rate of change of the earth's speed of rotation due to lunar tidal friction varies inversely as the sixth power of the moon's distance, and must therefore have been much greater in the past. An estimate of the time needed to bring the moon to its present distance, based on the supposition that the phase lag of the oceanic tides has always been as at present, indicates an age of the order of 4,000,000,000 years.

These two methods are much less accurate than those based on radioactivity. Their utility is that they both depend on theories that explain a large number of other facts, and that the agreement of their conclusions in order of magnitude with those drawn from radioactivity gives independent reason to believe that the latter are not vitiated by some fundamental error of principle.

The Expanding Universe—The reddening of the light of distant nebulae, if interpreted as a Doppler shift due to velocities away from the sun, implies that all the nebulae were fairly close together about 2,000,000,000 years ago. This suggests a similar age for the universe.

THE EARTH'S THERMAL HISTORY

The primitive earth was presumably very thoroughly stirred up. But the heavy metallic constituents refused to mix with the rocky ones and quickly settled to the centre to form the core. At some stage during the solidification the granitic and basaltic layers separated from the dunite one, and, by some process so far very imperfectly understood, the granitic matter became collected into large patches, which we know now as the continents. In a few thousand years the whole of the rocky shell would be solid.

The latter history is substantially modified by radioactivity. The amount of heat being conducted out of the earth per unit surface per unit time is the product of the thermal conductivity of the surface rocks, and the increase of temperature per unit depth. Both vary appreciably from place to place. On an average about 1.4×10^{-6} calories per sq cm is being conducted out of the crust in Britain, about 1.2×10^{-6} in South Africa. But the experimental work of the present Lord Rayleigh, J. Joly, J. H. J. Poole and others has shown that average granite in the same regions contains enough radioactive matter for 1 c.c. to produce 5×10^{11} calories per second. Hence about 2.8×10^6 cm, or 28 km, of average granite would supply all the heat leaking out at the surface. The actual thickness of the granitic layer, as we have seen, is about 18 km, but other rocks are also radioactive. We are forced to suppose that unless the radioactivity is practically confined to a surface layer with a thickness comparable with 20 km, the heat coming out of the earth would exceed its actual amount.

The temperature at any depth in the crust may be regarded as made up of two parts, one due to the original heat, the other to that developed by radioactivity since solidification. The age of the earth and the other relevant physical data being roughly known, the former part can be evaluated. Subtracting from the rate of conduction out of the earth the portion due to original heat, we are left with the part due to radioactivity. This is found to be equivalent to the rate of generation of heat by about 15 km of granite, or by 10 km of granite with 20 km of basalt under it, — in excellent agreement, so far as we can tell, with the results of seismology. If we adopt the latter view, the present temperature at the base of the intermediate layer should be about 560° C. At a depth of about 300 km the rocks should have cooled by about 250° since solidification, below 600 km the present temperature in the rocky shell is nearly the melting point. We can now easily see why the central core is liquid. The melting point of dunite at ordinary pressures is 1,400°–1,600°, that of pure iron is about 1,500°, but that of the material of the central core might be lower by some hundreds of degrees on account of im-

purities. In addition, the melting point of dunite is raised by pressure, that of iron is raised much less, if at all by pressure. Accordingly we should expect that the central core would be more fusible than the surrounding rock, and if the latter is near its melting point the iron must be liquid.

The foregoing discussion concerns mainly continental conditions. Radioactivity beneath the oceans must be less, and the cooling at great depths there may be up to 50% more. The upward concentration of radioactive matter requires an explanation. It is perfectly genuine for, without it, it would be impossible to reconcile the radioactivity of the surface rocks with the rate of increase of temperature inwards. Also it can be shown easily that if the radioactive layers were twice as deep or even if the total amount of radioactive matter were the same but were uniformly distributed to a depth of 100 km, the steady temperature at the base of the radioactive layer would be so high that the interior could never have become solid. A difficulty sometimes expressed about the concentration near the surface is that the elements concerned are heavy, and might have been expected to collect near the centre of the earth. But when the total amount of a substance is too small to affect the density of its solvent appreciably, the density is often of much less importance than solubility or volatility in determining the distribution.

Actually it is found that the radioactive generation of heat in basalt is under a third of what it is in granite, and in denser rocks such as dunite the amount is much lower again. This points directly to a strong upward concentration, especially if the dunitic analyses are, of course, surface samples, and have probably been enriched by contact with the more radioactive rocks that surround them. Further, Holmes has called attention to the fact that in successive igneous outpourings, even of material of similar composition, the material from the higher levels seems to have been enriched in radioactive materials at the expense of that lower down. The evidence that these subunits actually do tend to collect upward is very strong. The most probable explanation is that given by Goldschmidt, who gives reasons from crystallography why uranium and thorium cannot form part of silicate crystals but remain in solution to the last. In the earth the crystals would settle to the bottom and leave a radioactive layer on top. His argument was confirmed by Pigott, who found that the radioactive elements in rocks actually occur on cleavage planes and on interfaces between crystals, not in the interiors of crystals. Later denudation would tend to transfer the radioactive substances to the ocean bottom, as Joly pointed out.

The Effects of Cooling at Great Depths.—The fall of temperature since the solidification of the crust would be associated with a contraction in volume. But we have seen that, since the solid crust formed, the greatest rate of cooling is at an intermediate depth, which is at present somewhere about 200 km. The spherical shell of cooling matter becomes too small to fit the interior, but being plastic it stretches and becomes thinner. This makes its outer boundary move towards the centre, tending to leave the uncooled outermost regions unsupported. But they are not strong enough to support themselves, and collapse under their own weight. They have to accommodate themselves to too small a surface, and consequently crumple, fold and fracture. This is the thermal contraction theory of mountain formation. It is found that every great circle in the sphere would have to contract by about 400 km. The compression required to explain all known mountains is not accurately known but it appears to be of the same order of magnitude. The chief strength of the thermal contraction theory, however, is that it certainly accounts for a large fraction of the mountains of the globe, and as no other suggested theory has been proved so capable the presumption is that thermal contraction is the chief cause of mountain formation.

Further, the rocks beneath the oceans are more basic, and therefore are probably less radioactive and have cooled more than sub-continental rocks. Even at the same temperature basalt seems to be stronger than granite and when it is cooler it will be stronger still. Hence when an ocean floor is compressed against a continent, the latter will be the first to yield. This is the probable explanation of the Pacific type of mountains—the long series of

the Rockies and Andes with the smaller ranges running nearly parallel to them and to the neighbouring coast. The theory predicts a contraction composed of two parts, about equal in magnitude up to the present time. One increases nearly uniformly with the time, the other as the square root of the time. Only the latter part had been considered until 1932, and met with the difficulty that it would make the intervals between the great epochs of mountain formation much longer now than when the earth was young. This does not appear to have been the case, and formed the basis of a serious objection to the theory. The former part, however, is free from this objection and is probably responsible for most of the mountains formed since Cambrian times.

Mountain formation, on almost any mechanical theory, would be expected to be intermittent in time and localized in position. The upper rocks are elastic solids, which have to be under a considerable stress before they give way, and when they do so the yield is at a definite place and becomes complete almost instantaneously. If then the stress is one that grows very slowly and gradually, there will be long quiescent periods when the stresses are accumulating separated by short intervals when they are relieved by folding and fracture, with mountain formation as a result. This corresponds with the facts as known to geology.

The theory has, however, still to meet several difficulties in points of detail, while the phenomena of igneous activity, shown in volcanoes and intrusions, seem at present to stand right outside it. The temperatures that seem most probable within the intermediate layer are enough to make a hard glass reader to find that the intermediate layer actually is, nevertheless, basalt driven up to the surface seems to be much more completely fluid and to judge by its effects on neighbouring rocks, at a much higher temperature. A curious fact noticed by Aston provides what looks like a promising clue. The "inert gases" (helium, neon, argon, krypton and xenon) are far scarcer on the earth than one might expect from comparison with the abundance of other elements of neighbouring atomic weights in the crust: the ratio is in all cases somewhere about a millionth. A very natural explanation is that when the primitive earth was highly heated and probably distended its gravitation was insufficient to control the freely moving molecules of a gaseous atmosphere, consequently the truly gaseous constituents were mostly lost from the earth and transferred to the resisting medium. The present earth consists of the constituents, such as iron, that liquefied readily, and of the materials that formed liquid or solid compounds at the high temperature concerned. From this point of view it is interesting to note that the amount of oxygen in the earth's crust is within 1% of that needed to combine with all the other elements, and the rarity of the inert gases is to be attributed precisely to the fact that they are inert gases, and could not find even a temporary place of safety in the earth's interior. But if we adopt this explanation we must suppose that most of the water and carbon compounds on the earth's surface at present have been expelled from the interior since the earth shrank to its present size. There is ample independent evidence that chemically active gases and water vapour are continually being expelled from volcanoes, and T. A. Jaggar and A. L. Dry have given reason to believe that their reactions with one another and with the oxygen of the air are the principal factors in maintaining volcanic temperatures. A continuous fused layer is not available as an explanation of volcanoes. It would imply absence of ocean tides, and a perfection of isostasy that does not exist.

Continuous heating in the deeper crust would produce expansion and hence tension in the upper crust. This would lead to vertical cracks and violent igneous outpourings. On the views just given concerning the way radioactive materials become concentrated near the surface, the earth's crust must have had such a history in its earliest days, but denudation and other factors have obliterated all traces of it. On the moon, however, there has been no denudation, and an extensive system of fissures and craters is the moon's most prominent feature. Lunar vulcanism is then to be referred to the moon's earliest days and the upward movement of radioactive matter produced by it provides the reason why the internal heating ceased and there is no vulcanism on the

moon

Isostasy—It is clear from the geological evidence that the transport of large quantities of matter horizontally, so as to thicken or thin the crust locally by several kilometres, is a common feature of the earth's history. Now, all matter produces a gravitational field, and this redistribution would therefore be expected to produce disturbances of the direction and intensity of gravity. Numerical calculations of the amount of these disturbances can be made, but when they are compared with the actual local direction and intensity of gravity, as shown by the slope of the plumb line and the period of a standard pendulum, they are always found to be wrong. It would actually be nearer the truth to say that additional matter does not appear to attract the plummet or the pendulum bob at all, and that matter removed appears not to have attracted them. The law of gravitation cannot be wrong, the only possibility is that there is really little excess or deficiency of mass in these places, addition or removal of matter on top being compensated by the outflow or inflow of an equal mass below. This result would follow physically if the earth's upper crust was an elastic solid, but so thin as to be readily flexible, and rested everywhere on a fluid interior.

FIG. 4.—DIAGRAM ILLUSTRATING THEORY OF ISOASTASY ACCORDING TO WHICH EQUILIBRIUM IN THE EARTH'S CRUST IS MAINTAINED BY FLOW OF ROCK MATERIAL BENEATH THE SURFACE UNDER GRAVITATIVE STRESS
a, granitic layer, b, intermediate layer, c, lower layer

This theory was actually suggested as an explanation by Sir G. B. Airy when attention was called to the facts by Archdeacon J. H. Pratt. Extra mass on top would force the crust down, the fluid below would flow out, and the process would continue until just enough had flowed out to restore the balance, in the "isostatic" state every vertical column of the same section would have the same mass inside it. Pratt did not accept this explanation, and proposed as an alternative the idea of a "depth of compensation", according to him the extra mass of a mountain is compensated by a uniform reduction in density of all the matter below it, down to a fixed depth. This hypothesis requires that the matter should diminish in density when an extra pressure is placed on top of it, and therefore is physically unpalatable, and there are also weighty geological arguments against it. But most geodesists, especially J. F. Hayford and W. Bowie in the United States, have adopted Pratt's view and found it to correspond well with the facts. W. Heiskanen, however, showed that the Airy theory fits the facts at least as well, and H. Jeffreys showed that this result was inevitable from the nature of the law of gravitation. The chief modification needed in the Airy theory is that the substratum is not a fluid, but a very stiff solid, capable of transmitting distortional waves, but weaker than the outer crust. The weakness

of the facts. It is nowhere exact, and in some regions is seriously wrong. Though it is true that the substratum is weaker than the outer crust, it is not devoid of strength. There are widespread

variations of gravity, which imply corresponding variations of load, too great to be supported by the strength of the outer crust alone. Their support requires considerable strength, about a third of that of surface rocks, to a depth of about 600 km, which corresponds to the focal depth of the deepest earthquakes.

EARTH, FIGURE OF THE see GEODESY

EARTH CURRENTS in the widest sense are any electric currents flowing in the earth. Technically, however, the term excludes all artificial currents due to grounding, leakage or inductive effects from power systems. It also excludes some natural currents which are purely local. Currents generated by chemical activity of certain ore bodies, or by temperature differences in the earth, and surges due to lightning discharges have this local character and are not included in a discussion of earth currents. The existence of earth currents, *i.e.*, induced currents of wide extent and of origin quite distinct from any of those enumerated, was probably first suggested by Sir Humphry Davy, 1821. Michael Faraday, 1831, although unable to detect them with then-existing instruments, was convinced of their reality when he discovered the principle of electromagnetic induction. In 1847 W. H. Barlow obtained the first actual evidence of earth current flow from measurements on English telegraph lines, and detected a diurnal variation in it. About the same time C. V. Walker also obtained records from telegraph lines chiefly of the large currents flowing during disturbances or earth current storms. These and similar early investigations, although fragmentary in character, soon showed correlations between earth current disturbances, magnetic storms, aurorae and changes in solar activity as indicated by sunspot numbers. Thus the concept of earth currents as a world wide rather than a local phenomenon became established, and more formal investigation of them was undertaken.

Systematic continuous observations of earth currents were carried out at a number of European stations during the last third of the 19th century and several valuable series of records were obtained. Early among the important series were those at Greenwich, England, started in 1865, and continuing with some modifications until after 1890 at Berlin (1883-91) reported in detail by B. Wensten and at Parc St. Maur, Paris, shortly afterward. The rapid expansion of electric railways toward the close of the century put a check on recording at many places. The large grounded currents from railways forced the abandonment of the programs at Greenwich and Paris and made such measurements impossible in any densely populated region. After a decade or so of neglect, the study of earth currents was undertaken once more at Elbro, Spain, in 1910. The Elbro records covering the years from 1910 to 1938 are the most extensive yet obtained and have been widely used for analyses. More recently installations for continuous recording on duplicate lines were made at Waterloo, Western Australia, in 1923, and at Huancayo, Peru, in 1926. The use of duplicate lines made available independent records from lines of different lengths as a check on the operation of the measuring systems. Both of these stations, operated by the Carnegie Institution of Washington, were still recording in 1945. The Carnegie Institute in co operation with the U.S. coast and geodetic survey and the Bell Telephone laboratories, also secured records on long telephone lines at Tucson, Arizona, from 1931-43. The Carnegie Institute, during the second international polar year 1932-33 secured 18 months of record at College Fairbanks, Alaska, and the Canadian Meteorological service co operated in obtain

ing a year's record at Chesterfield Inlet, Northwest Territories, Canada. At the same time other high-latitude records were secured at Sodankylä, Finland and Tromsø, Norway. Other earth current investigations covering varying periods of time have been carried out in the United States by the Bell Telephone laboratories, in Sweden (also on communication lines by D. Stenquist), at Allahabad, India, and in Russia, South America and Japan. After 1939, wartime conditions radically curtailed most geophysical investigations and no new earth current measurements were reported up to 1945. That year the only earth current installations reporting were the stations of the Carnegie Institution of Washington at Watheroo and Huancayo and one station operated at Riverdale, N.Y., by the Bell Telephone laboratories. The Riverdale station was used chiefly for studies of disturbances in correlation with magnetic disturbances and ionospheric changes as an aid to the prediction of radio transmission conditions.

Measurements.—Direct measurements of earth currents are not practicable. Hence information on their magnitudes, directions and other characteristics must be inferred from measurements of potentials combined with records or estimates of the resistances of their paths of flow. In most cases only potential measurements have been made. For this reason the results are usually given in units of potential or potential gradient and not of current or current density. Superficially, the potential measurements are simple. They are made with galvanometers or potentiometers connected between two earthed points, the orientation and distance apart of which are known. At least two pairs of points lying on lines of different azimuths are required to determine the magnitude and direction of the gradient. Evaluation of the results in terms of earth current potential gradient is not simple, because the potentials measured are almost never those due to earth current flow alone. Whenever electrical connection is made between two points in the earth, some potential will practically always be found to exist between the two electrodes making the contact, even when there is no current flowing through the ground. These contact potentials are caused by electrochemical activity between the electrodes and the surrounding soil and are quite independent of any current which may be flowing through the ground. They may also be many times as great as the potentials due to earth current flow and unless the equipment is carefully selected, may vary widely with time. The potentials recorded, then, are combinations of the contact potentials and those caused by current flow. Potentials due to extraneous local currents are also picked up where they exist. Allowance for contact potentials and for local current flow must be made if the earth current records are to have any value. Neglect of this fact has sometimes led to grossly inaccurate conclusions, such, for instance, as the existence of a large constant component or unidirectional flow of earth currents. The effects of local current flow can well be excluded by care in the selection of the site of measurement. Since contact potentials are independent of the length of line, or distance separating the two electrodes of a pair their effect can be minimized by using very long lines. This was done at Berlin where lines 120 and 260 kilometres long were used for the northerly and easterly components respectively. The next longest lines on record were those at Tucson, 57 km for the northerly and 94 km for the easterly line. Shorter lines are cheaper and more convenient and even on lines as short as 1 km effective elimination of the effects of contact potentials can be attained by using duplicate lines. This is done at Watheroo and Huancayo where independent records of each component are secured on two or more lines of different lengths. In reducing the data only those features of the records are used which are common to both records and proportional to the lengths of line.

Established Facts.—The first point to be emphasized in discussing the results of these investigations is that there is no valid evidence of the existence of a constant or unidirectional part of earth current flow. Some early conclusions to the contrary resulted from mistaking contact potentials and their variations for true earth current potentials. The records obtained from the duplicate lines at Watheroo, from the long lines at Berlin and Tucson and from tests with special electrodes at Jaro and

elsewhere, demonstrate this fact conclusively. In other words, earth currents as determined at any single station are essentially pulsating or alternating currents differing from usual transitory or alternating currents in the relatively long periods of their variation. Hence all inferences drawn from potential measurements must be based on a study of their variations and not on the absolute values recorded.

Disturbances, Earth Current Storms.—The variations most conspicuous in records of earth potentials are irregular fluctuations, sometimes of brief duration and sometimes continuing for several days. Those of short duration are referred to as disturbances, while the more lasting, and usually more intensive, fluctuations are commonly called earth current storms. Earth current storms occur on the average six or seven times each year. Most of the severe storms are world wide and are often characterized by sudden commencements at which times sharp fluctuations appear simultaneously at stations all over the world. It is difficult to fix on simple quantitative measures for these storms because of their complexity. In severe storms potential gradients as great as 100–200 mv/km. have been recorded at middle latitude stations and higher values at polar stations. A clue to the origin of earth current storms is found in the examination of other geophysical phenomena. Earth current storms always coincide in time with magnetic storms and the fluctuations noted at a given station can generally be correlated with those in one or another of the magnetic elements. The frequency and intensity of aurorae and of unsettled conditions in the ionosphere are also found to increase markedly at times of magnetic and earth current storms. These facts point definitely to a connection between all these phenomena and solar activity. Comparison with sunspot numbers shows that the intensity and frequency of both magnetic and earth current disturbances are greatest near the times of sunspot maximum and least at sunspot minimum and all three vary in much the same way throughout the well known cycle of approximately 11 years. Moreover, a 27 day recurrence, corresponding to the sun's rotation, and so to the reappearance of a group of spots, has also been found in such disturbances. Disturbances of short duration are apparently more localized. Their frequency and intensity are greatest at high latitudes both in the earth current and magnetic records. Typical disturbances are found to coincide with bright chromosphere eruptions and radio fade outs which accompany them. The intensity of these disturbances falls off with the distance from a point directly under the sun. A study of brief isolated disturbances at College Fairbanks showed a high degree of correlation with observed aurorae and comparison with records from other stations further indicates that the same disturbances, greatly reduced in magnitude and modified in appearance, can be identified in the records at middle latitude and even equatorial stations.

Periodic Variations.—Storms and disturbances are representative of unusual conditions. Less spectacular but more informative is the normal earth current flow which occurs day in and day out with remarkable regularity. Again we deal with variations, but variations which are far more regular and periodic.

Diurnal variation data, showing the changes in normal flow during the solar day, are available from a dozen or more stations. Prior to 1924 the distribution of these data was unsatisfactory since most of the earlier stations were close together in Europe. The establishment of the stations at Watheroo and Huancayo and the records obtained during the polar year, 1932–33, made it possible to compare the diurnal variation at stations distributed in latitude from 65° north to 30° south. At stations in middle latitudes the potentials measured in a north-south direction are decidedly greater most of the time than are those determined on an east-west line, and the general direction of current flow corresponds rather closely to the magnetic meridian. Here the diurnal variation curves are of double period with a marked maximum of current flow toward the equator near local noon. Greatest flow away from the equator occurs during the morning and afternoon hours. At Huancayo, close to the equator a distinctly different type of diurnal variation curve is obtained with a single pronounced maximum and minimum which occur roughly

FLANKING, TERRESTRIAL MAGNETISM AND ELECTRICITY—MCGRAW HILL BOOK COMPANY INC

FIG 1—EQUATORIAL VIEW OF POSITION OF EARTH CURRENT SYSTEM AT 19 HOURS GREENWICH MEAN TIME

FIG. 2.—POLAR VIEW OF POSITION OF EARTH CURRENT SYSTEM AT 10 HOURS GREENWICH MEAN TIME

at the times when the flow at middle latitude stations is zero. Also the direction of current flow is more nearly at right angles to the meridian than along it. The records from the polar year stations cover only relatively short periods of time and are less accurate. They do, however, indicate that the diurnal variation changes again as high latitudes are reached with a tendency towards single periodicity and predominance of the west east component.

By combining the data from the best of the modern stations, O. H. Gish, in 1936, constructed a generalized world picture of the normal earth current circulation, based solely on observations without recourse to speculation or arbitrary assumption. Two views of this are seen in figs. 1 and 2 in which the density of the arrows represent density of current flow as obtained by integrating the longitudinal flow throughout the day and their direction is that determined directly from the diurnal variation curves. Lines drawn through the arrows to represent continuous lines of flow complete the picture of currents flowing in a number

of large whorls or eddies. At the instant shown in these charts it is midday in the western hemisphere and the four whorls which fall in this daylight section are strong and well defined. The corresponding group of eddies on the dark side of the globe indicate much feebler activity. The current system must be understood to be fixed in space with reference to the sun and not to any spot on the earth. Hence 12 hours later the stronger eddies of current will be found flowing in Europe and Asia instead of in the Americas. Fig. 2 shows a secondary series of whorls as indicated by the polar year records. If one considers what happens as a point on the map is moved from left to right across the whorls, the significance of all the main features of the diurnal variation, such as the generally longitudinal direction of flow at middle latitude stations, the large surge of current towards the equator near noon and the reversals of direction during the forenoon and afternoon, is obvious. Fig. 1 also shows why the diurnal variation curves tend to be simpler in form at stations near the equator and the direction of current flow there

is confined largely to a west east line. The picture is, of course, necessarily generalized and qualitative since only a comparatively small portion of the earth has been covered in earth current measurements. Moreover, in its preparation such factors as the resistivity of the earth and the nonuniformity of the earth's magnetic field were neglected. Even if complete data were available, an exact picture could not be presented in a single diagram since the current whorls must tend to be modified as they encompass different portions of the earth. The resistance of the current paths, for instance, is quite different for a deep oceanic region and for continental areas. Consequently the whorls themselves tend to be modified considerably in shape and in intensity as they progress around the earth. So the entire picture must be viewed as oversimplified for the sake of clarity.

The seasonal changes in normal earth current activity are chiefly changes in intensity. The magnitude of the flow observed in individual months shows a definite minimum at midwinter and less pronounced maxima at the equinoxes. A very similar seasonal variation is found in the magnetic records. Referring again to fig. 1, it appears that the current whorls become most pronounced when the sun is directly over the equator and weakest in the hemisphere farther away from it at other times. At most stations only minor changes in the type of diurnal variation are noted throughout the year. A notable exception is Tucson, which, it will be noted, is located near the centre of the northern hemisphere whorls. There, as the current pattern moves up and down following the motion of the sun, the station is apparently alternately south and north of the centre and, as a result, quite different phase relationships exist between the two components in summer and in winter months.

The annual variation in normal earth current activity again consists mostly of changes in intensity. B. Weinstein from the Berlin data, D. Stenquist and L. A. Bauer using Ebro results and W. J. Rooney from the records at Watheo, Huancayo and Tucson, all find that the normal activity, as well as disturbance effects, follows closely the variations in sunspot number, and its changes from year to year are very like the variations found in the earth's magnetic field.

A lunar diurnal variation, consisting of a double period oscillation, was shown in the Ebro records by J. Egedal and in the Huancayo and Tucson records by Rooney. This variation is attributable to tidal action in the ionized layers of the upper atmosphere and is a clue to the mechanism causing earth current flow.

Relation of Earth Current and Magnetic Variations.—The parallelism between earth current and magnetic variations is too close and too consistent to be accidental. It extends not only to the frequency of disturbances and similarity in seasonal and annual changes but also to specific features such as the unusual seasonal variation at Tucson or the simultaneous occurrence of unexpected conditions on individual days. The relationship is, however, not a simple one and its exact nature has yet to be determined. Theories underlying the variations in the two, developed by A. Schuster, S. Chapman, R. Gunn and others have been summarized by O. H. Gish. All the more tenable theories agree in concluding that the variations in the earth's magnetic field and the flow of electric currents in its crust are the result of currents circulating in the upper atmosphere. These ionospheric currents in turn depend on its becoming highly conducting under the influence of solar radiation. There is some difference of opinion as to the precise mechanism and even as to the exact type of radiation involved but two fundamental facts are clear. The existence and general character of the ionospheric currents have been clearly demonstrated through the modern advanced technique for their investigation. And the fact that such currents must modify the earth's magnetic field and cause it to vary is undeniable. These magnetic variations then induce current flow in the earth which in turn reacts on the magnetic field to modify it still further. The net result, under normal solar conditions, is the regular periodic variations in the magnetic field and the accompanying earth current circulation such as that depicted in figs. 1 and 2. Storm and disturbance effects require some differences in radiation and in the complexity of the mechanisms

but are also quite definitely of a solar origin (See also *ELECTRICITY, TERRESTRIAL MAGNETISM*).

EARTHENWARE, a term generally associated with a coarser type of domestic pottery, although such cups and saucers and other tableware of thin pottery are often called chint (see CHINAWARE) in error.

Earthenware can be made almost as thin as china, but it lacks translucency, it is opaque. Its chief feature is that it will absorb moisture under the glaze whereas china will not. A test adopted by the British customs officials is the application of red ink to the ware at a point where the glaze has been removed. If the ink is absorbed then it is classed as earthenware.

Earthenware embraces a wide range of pottery (see POTTERY AND PORCELAIN) known under a variety of names, which usually indicate the place where the ware was first introduced. William Burton, a well known authority writes "The word earthenware in its widest sense might be used to cover all varieties of pottery, as they are all made from some form of earthen or mineral substance taken out of the ground. In this broad sense a brick, a drainpipe and a Chinese vase might be equally described as earthenware, but though the chemical differences between them are slighter than would be supposed, they are so far apart in technique and final result that the names earthenware, stoneware and porcelain are very conveniently used to differentiate between them. In this restricted sense, the title 'earthenware' covers all articles made from a single natural clay, or from mixtures of clay and other mineral substances which when sufficiently fired for practical use, still remain porous, and need, therefore, if they are to be used for culinary, domestic, or decorative purposes, to be completed by the addition of an outer skin of glaze or glass melted on them." A handbook compiled by British experts in conjunction with the educational committee of the Pottery and Glass Trades' Benevolent Institution, gives the following definition of earthenware—

"All ware may be termed earthenware which is porous in the material itself, and requires to be glazed before it can be applied to domestic use. Earthenware is opaque, it will not transmit light."

The porosity of the "body" (the pottery itself without a glaze) may give a wrong impression to those who are not familiar with the ceramic industry. For instance, Bourry, a noted authority on the industry, points out that terra cotta and stoneware are quite distinct in their properties. One of the chief characteristics of stoneware is its impermeability, whereas terra-cotta has a porous body. If the distribution of the temperature of the kiln is irregular, some of the ware, says Bourry, will be impervious and rightly termed "stoneware," whilst other ware, in the same kiln, will have a porosity between that of terra cotta and stoneware. Judged on the basis of porosity, an article, Bourry points out, might be defined as "stoneware" if viewed from one side and as "terra-cotta" if viewed from another! Therefore it will be seen that earthenware and other types are not easily defined, but for general purposes the term "earthenware" may be applied to pottery which is absorbent under the glaze.

Types of Earthenware.—Earthenware can, however, appear under several names, each chosen to distinguish a special type of ware. These are sometimes distinguished in the trade as agate ware, onyx ware, marbled ware, porphyry ware, that is, earthenware made to imitate these various natural stones by mixing different coloured clays and glazing with a rich soft glaze.

Delft ware is a general term applied to earthenware covered by an opaque tin enamel. It takes its name from Delft in Holland, where it was already largely made about 1600. Afterwards, it was imitated at Lambeth, Bristol and Liverpool (England).

Talcum ware is an earthenware with a soft rich glaze, generally decorated under the glaze, named after the place of its origin, "Fayence."

Majolica ware is the name given to an earthenware which is glazed with soft coloured glazes. It takes its name from Majorca.

Chinaware is a yellow or cream coloured English earthenware first made about 1750 by Josiah Wedgwood of Etruria (England). Many imitations of it have been made, which vary much in character, colour, hardness and quality.

Some porcelain and ironstone china are only trade names given to a harder form of earthenware. They are not in reality either porcelain or china.

The above descriptions cover in the main table ware and decorative pottery, but earthenware is also used for more prosaic purposes such as sanitary utensils, and containers for food and drink. Earthenware is also produced in almost every civilized country of the world, but the quality varies considerably. In this respect Great Britain has an enviable reputation for its earthenware, just as it has for china.

Not only will the ware itself differ in its quality, according to the country of origin, but the decorations also are in most cases characteristic of the nation that produces the earthenware, unless it is made specially for export. For instance, an eastern country like Japan expresses its artistic character in its pottery decorations, but to capture the trade in western countries forsakes its national decorative schemes and adopts those common in the Western Hemisphere.

The principal raw materials used in the manufacture of earthenware are china clay ball clay, flint and china stone.

China Clay—This mineral is found in many parts of the world, but the English mines at Cornwall and Devon are considered to produce the best clay for china making. The clay is, of course, consumed largely by the British potters, but large quantities are exported, particularly to the United States, which have not a clay of the English quality, although quite good clays are found in Georgia.

The British trade returns do not show the exports of china-clay separately, but group them with china stone. Of these two minerals 651,990 tons were sent abroad during 1926, more than half the quantity (361,797 tons) going to the United States. England follows with 64,891 tons, and the Netherlands ranks third with 40,421 tons.

According to the last census of production, published in a series of preliminary reports during 1926, the output of British china-clay was 805,000 tons, valued at £1,448,000. The previous census taken in 1907 gave the production of china-clay and china-stone together, the total being 726,000 tons, valued at £542,000.

Perhaps the next most important deposits of china-clay are to be found in Czechoslovakia, where an output of 40,000 tons per year is obtained. The best clay in Czechoslovakia is mined at Sedlitz and Karlovy Vary. Czechoslovak clay is also exported to the extent of about 20,000 tons per year, a large part of this being sent to Germany.

China clay is said to have resulted from the decomposition of granite through many centuries. Its main constituents are silica and alumina, and may be described generally as a white, amorphous powder. The clay is not usually mined in the ordinary way, but is washed down from the sides of the mine by huge jets of water thrown out of hosepipes at a high pressure. The water brings down the fine clay to the bottom of the mine, where any sand is allowed to settle out. The watery mixture of clay is then pumped up to the ground level, and run through a series of troughs, known as "micas," where it undergoes a process of levigation, which consists of running the mixture into a trough from which the clay and water overflow into another trough, and so on throughout the series. While the mixture is passing through the "micas," the heavier materials—the impurities such as mica—gradually settle out and are left behind. On emerging from the "micas" the clay, now pure, is run into settling pits. From here it will pass to storage tanks and then to drying kilns. Finally it travels, in the form of lumps, to the storage room or "linhay,"

from which it will be loaded into railway trucks or conveyed to ships. It is the china clay that gives plasticity to the mixture of materials used by the potter.

Ball Clay—This is found principally in Devon and in Dorsetshire, and is sometimes known as blue clay, owing to its greyish blue colour, which is due to organic matter. When fired at a moderate temperature it becomes white and remains absorbent, but some clays, if subjected to intense heat, are, according to Sandeman, rendered so hard that they are not easily scratched with a knife. Under such conditions these clays turn a yellowish colour and become non absorbent.

The clays vary, and the producer grades his clays into several qualities. Deposits will in some instances be found quite near the surface, while in other cases shafts will be sunk and the clay mined in branching "lanes," which vary in height according to the thickness of the vein of clay. It is necessary to "weather" the clay before sending it to the potter. To do this it is piled in heaps and exposed to the weather, and to the sun, rain and frost, probably for years, the whole being turned over at least once, so that all the clay may benefit from the exposure. This weathering is said to increase the plasticity of the clay, an important matter to the potter.

The production of ball clay in the United Kingdom according to the census published in 1926 was 146,000 tons, which had a selling value of £128,000. The United States bought 17,870 tons in 1916, more than half the quantity exported that year, Italy and Belgium following with 4,660 and 2,167 tons respectively.

Flint—Almost everyone is familiar with the pebbles or pieces of flint which are washed smooth by the waves on the seashore. These find their way into the body of earthenware. Not all flints are equally suitable, the best are found in France, although there are many other sources of supply. To reduce the flints to a powdery mass so that they can be incorporated into the clay, the pebbles are heated (or calcined) a process which not only turns them white, but makes them more amenable to grinding. They are first of all crushed and then ground into very small particles in water, so that a white, or greyish, thin liquid paste is produced.

The flint can withstand very high temperatures and therefore makes what might be termed a framework for the clay and other materials in the earthenware. The census of production for the United Kingdom published in 1926 gives a total of 188,000 tons for flints (including crushed and broken flints).

China Stone—This is an important ingredient in pottery, and there are deposits of a high quality in Cornwall, England, where the stone is mined by inserting explosive charges in holes drilled by compressed air boring machines. The stone has four recognized qualities or grades: hard purple (a white, hard rock with a purple tinge), mild purple (similar but softer), dry white or soft (a soft white rock), buff (similar to dry white, but with a slight yellow tinge).

Silica is the principal constituent, amounting to about 74% in the dry white and over 80% in the three other varieties. Oxide of alumina is the next important ingredient, amounting to about 18% in the dry white and from 7% to 10% in the other varieties. The British output, according to the preliminary census reports published in 1926, was 51,000 tons, valued at £32,000. China stone gives the china "body" its translucency.

Manufacture of Earthenware—Earthenware may be "thrown" on the potter's wheel or made under semimechanical conditions. In the case of the potter's wheel the prepared ball or lump of clay, revolving at the will of the potter on a small circular platform, is moulded by hand into whatever shape is aimed at. But for commercial production on a large scale, the thrower may form the ware in a mould which shapes the exterior, the clay being pressed inside until the desired thickness is attained, or the clay and other materials may be introduced in the form of "slip" (a mixture of the materials with water) into a plaster of paris mould. A further method is that of "jolleying." In this process a mould forms one side of the article. If "flat" ware, such as saucers, plates, etc., is being made, the mould shapes the top or inside, and the underside of the ware which is on top in this process, is fashioned by cutting away the clay, as it revolves, by means

of a tool which is cut to represent the profile of article to be made. The lathe also plays a part in finishing raw, or "green," clay articles. These processes are described and illustrated under CHINAWARE.

Unlike china, earthenware has little beauty of its own, also, is already fired, it is necessary to cover it with a hard glaze before it can be used for domestic or most ornamental purposes. Its decoration may be applied by painting or printing designs under or over the glaze, or the decoration may consist of coloured glaze, in one colour or a variety of shades. A glaze is really a glass, and this may be coloured with various metallic oxides. The oxides produce different colours according to the temperature of the kiln and the method of heating. A variety of colour schemes is possible, but it is a speculative method of decoration for it is difficult accurately to predict what the colours will be when they emerge from the kiln. This element of chance is made use of by some potters, for it truthfully can be said that no two pots decorated in such a manner will be identical.

To perfect the decoration of pottery by the fusing of metallic oxides and a flux on the ware the potter needs to have a scientific knowledge, that is, he must understand the chemical and physical properties of the metallic compounds, so that he may judge what their behaviour will probably be when subjected to heat in the kiln. With such knowledge some beautiful effects may be produced, but many glorious combinations of coloured glazes have been the result not of predetermined efforts, but of unforeseen happenings in the kiln. When the green or raw clay article has been made, it is fired or heated in an oven. The glaze is then applied and the ware is fired again. (See CHINAWARE.) (G C)

EARTH INDUCTOR COMPASS The term earth inductor compass generally relates to a certain device used in some improved aircraft magnetic compasses. The inductor, in one form or another, is used as a detecting unit which by various means actuates direction-indicating devices. Representative forms of the inductor compass are shown in the schematic fig 1-5.

The term *inductor* designates that class of magnetic compass devices which work on the principle of induced voltages and electric currents. A voltage is induced when there is relative motion between a conductor and a magnetic field. Electrical engineers say, more properly, that voltages are generated when there is a rate of change of flux linkage. If the conductor is a closed circuit, the induced voltage causes a current to flow. A conductor may sweep through magnetic lines of force, or it may be stationary and the magnetic field may move, in either case generating a voltage. The earth's magnetic field is regarded as stationary with the earth, but it may be made to move locally by distorting a section of it. Some of the devices described herein work on the principle of voltages generated in moving conductors. Others function by periodic moving or distorting of the magnetic field. By distortion of the magnetic field is meant bending or "detouring" it (distortion of the earth's magnetic field is not shown in the illustrations).

Fig 1 is an elementary sketch of the type of instrument that was used in round-the-world and early transatlantic flights. Col Charles A. Lindbergh used this form of compass in his famous flight. The inductor in this case comprises a coil, which by its rotation in the earth's magnetic field causes variation in the flux linkage which generates an alternating current voltage. The resulting alternating current voltage is rectified by means of the commutator and brushes, as shown. The rectified current will then indicate on the D C meter. By rotating the brush assembly with respect to the earth's magnetic field, the polarity of the D C voltage is changed. At one particular brush setting, the meter indication is zero. When the brushes are fixed to the vehicle, it is possible to steer the vehicle so that the meter continues to read zero. Deviations from the course will cause the meter to deflect right or left, depending on the direction of departure. By restoring to the proper heading the meter again reads zero. To select a different heading, it is necessary only to reorient the brushes with respect to the vehicle, and a new straight course with respect to the magnetic meridian can then be steered.

Fig 2 is the second form of this device, which though operating differently, may still be considered an inductor compass. A magnetically permeable "Z" shaped core rotates while the coil is sta-

tionary in the horizontal plane. A voltage is generated in this coil by the periodic distortion of the earth's magnetic field, which causes variation in the flux linkage of the coil. The A C voltage, thereby generated is rectified to a direct current which indicates on the meter. A straight magnetic course can be maintained by selecting the heading such that the meter reads zero.

A third form is shown in fig 3. This is essentially a permeable magnetic core which concentrates the earth's magnetic field. It is mounted so that it is rotatable in the horizontal plane. When the

FIGS 1-4—FOUR TYPES OF ELEMENTARY EARTH INDUCTOR COMPASSES. See article for full explanation. In fig 4 F indicates fundamental or supply frequency while 2F indicates twice fundamental or twice supply frequency.

core is parallel to the horizontal component of the earth's field, *ie*, north-south, it collects the maximum amount of flux. When it is at right angles to the horizontal component of the earth's magnetic field, *ie*, east-west, it does not collect the earth's field flux. By turning it slightly from the east-west direction either one way or the other, the direction of flux collected in the core reverses. Coils are wound around the core. In the middle of this core is a continuously rotating magnetically permeable section which periodically varies an air gap. This changes periodically the reluctance of the core as a whole. In any given orientation in the earth's field, therefore, that portion of the earth's field that passes through this core is periodically pulsed. This action induces an A C voltage in the coils. This voltage is minimum in the east-west orientation and is maximum when north-south. Furthermore, the phase of the voltage is reversed in rotating through the east-west position through a very small angle. After rectification by the commutator this phase change becomes a reversal in D C polarity, therefore the magnetic orientation of the magnetic core and brush assembly is detected by the meter. When the meter is in the central position the core is then oriented magnetic east and west.

A further extension of the inductor compass principle is illustrated in fig 4. This introduces the idea of the flux valve. The

term *flux valve* denotes a device in which the earth's field is pulsed or varied by periodic distortion. In the flux valve there are no rotating mechanical parts. It comprises a permeable magnetic core which has the property of collecting the lines of force of the earth's magnetic field as in the device of fig. 3. The mechanically rotating part is omitted; in its place there is a cross section of the magnetic core which serves as a path for an additional magnetic field produced by a central coil, as shown. This magnetic field alternates because the coil is excited from an alternating current source. At each half cycle the flux of this magnetic field is of such value that it tends to saturate (overload) the closed portion of the magnetic core. This saturation occurs cyclically since the flux alternates periodically. Saturation of the core changes the reluctance or the ability of the core to pass the mag-

netic flux. This is accomplished by means of gears. As in the preceding forms, a straight course can be steered by holding the meter reading to zero. The course is changed by orienting the flux valve differently with respect to the craft. A card may be attached to the flux valve which indicates the magnetic heading when the meter is at zero.

In the four types shown fig. 1-4, there are two common defects which show up in their use as navigation compasses. The first is that they are so called "zero reader" indications and therefore do not indicate magnetic direction without manipulation. Secondly, they lack stabilization. By the latter is meant that the motion of the craft may affect the accuracy of the reading. This is explained by the fact that where the earth's magnetic field has appreciable dip angle (which prevails over 9/10 of the globe) only the horizontal component of this field may be used to determine direction. In an aeroplane, to obtain the horizontal component, the earth inductor device is put in gimbals and made pendulous so that it normally keeps the inductor in the horizontal plane. However, due to rough weather conditions, it will stay in the horizontal plane very little and the readings become so erratic that the compass is useless.

One way of avoiding these faults of elementary inductor compasses is to make the inductor in the form of a "flux valve" as shown in fig. 5. Having effectively three poles instead of a single one, the respective coils on each pole cannot all have zero induced voltage at the same time. The voltage in each coil, however, is still dependent on its orientation with respect to the earth's magnetic field. Therefore, measurement of the voltages of each coil will permit, by proper interpretation, determination of magnetic north. This is done automatically without rotation of the flux valve itself and, therefore, the operation of mechanically rotating the inductor device to a zero output position is eliminated. The revolving device that interprets the voltages is called a signal transformer. The signal transformer includes a stationary unit having coils electrically connected to the three radial coils of the flux valve and distributed respectively in the same order. There is an additional part of the signal transformer, the central rotor, which carries a signal coil that is rotatable. By transformer action, the rotatable coil induces a voltage depending on its angular position relative to the voltages in the stator coil. This coil, therefore, has a zero voltage angular position in a manner similar to that of the single axis flux valve shown in fig. 4. To determine direction, the rotor of the signal transformer automatically rotates the zero voltage position.

As was indicated, the elementary types of inductor compasses have another fault, and that is lack of stability. Also shown schematically in fig. 5 is a modern method of overcoming this defect. The directional gyroscope is now introduced. This is a navigational instrument familiar to all airmen. It has the property of holding for fairly long periods of time a given heading with no oscillations or turning errors to which magnetic compasses are subject. This device, however, does slowly drift off the correct indication and therefore needs to be restored occasionally in flight. By linking a flux valve to the directional gyro, the latter is automatically and continuously oriented to the magnetic meridian, therefore, a stable continuously indicating magnetic compass is obtained. Without discussing the controls of the gyroscope, it can be stated that the rotor of the signal transformer is driven in azimuth direct from the directional gyro. There is a precession control of the gyroscope that orients it or makes it rotate slowly around the vertical axis. This precession is produced by the voltage of the signal transformer rotating coil. The resulting rotation of the gyroscope is in such a direction as to make the rotatable coil move toward its zero voltage position. In other words, the gyroscope is kept oriented to the null position. Since this null position is determined by the angular position of the flux valve in the earth's magnetic field, it satisfies the requirement of automatically and continuously restraining the gyroscope in correct alignment with the magnetic meridian. The azimuth scale attached to the gyroscope therefore indicates the magnetic heading of the aircraft at all times. (See also NAVIGATION TERRESTRIAL MAGNETISM.)

(O. E. F.)

FIG. 5.—EARTH INDUCTOR COMPASS

An advanced type of inductor which overcomes the defects of lack of stability and inability to indicate magnetic direction without manipulation. F indicates fundamental or supply frequency while 2F indicates twice fundamental or twice supply frequency. The Gyrocompass is built on this principle.

netic flux. This saturation is periodic, and therefore the reluctance can be said to vary periodically. The periodic change in reluctance of part of the magnetic core affects that portion of the earth's magnetic field that also passes or tends to pass through this part. Since the reluctance varies periodically, the earth's field component will vary periodically. Periodic change in this component of flux induces a voltage in the coils which surround the actual members of the core. This is an AC voltage, and its magnitude varies with the average amount of earth's field threading through the core. This voltage in the same manner as in preceding examples, is therefore a measure of the position of the core relative to magnetic north. It should be mentioned that the voltage induced in the coils is at double the frequency of the excitation current. For explanatory purposes, an AC generator is shown driven by a motor. The output of the flux valve is fed back through slip rings to a commutator driven by the same motor. This rectifies the signal. Since the output is twice the frequency of the excitation current, however, the commutator must go at twice the speed of the AC generator. Therefore, there must be an exact two to one increase in speed between the generator and

EARTHNUt, the English name for *Conopodium dnnuatum*, a member of the family Umbelliferae, which has a brown, tuberlike rootstock the size of a chestnut. It grows in woods and fields. It has a slender, flexuous, smooth stem 2 to 3 ft. high, much divided leaves and small white flowers in many rayed, terminal, compound umbels. Though excellent in taste and unobjectionable as food, it is disregarded in England by all but pigs and children. In the Netherlands and elsewhere on the continent of Europe the rootstocks are generally eaten. The name is applied also to the fruit of *Arachis hypogaea* (family Leguminosae) which is also known as the peanut, groundnut (*qq v*) or monkey nut.

EARTH PILLAR, a column of soft rock, or earth which has not a homogeneous structure throughout, but contains large blocks embedded in much finer material. By exposure to conditions of denudation, especially rain action, the large blocks protect the material beneath and so, by differential action the earth pillars are produced. Glacial drift and moraine deposits are ideal substances in which earth pillars can be formed and these structures are therefore found in regions of recent glaciation. Earth pillars are most likely to be found where the climate is semiarid with precipitation concentrated. The "bad lands" of western North America furnish excellent examples, and there are specimens in Tirol and other parts of the Alps, in Scotland and in the Dead Sea region.

EARTHQUAKES The study of earthquakes, called seismology, may be divided somewhat arbitrarily into three parts: (1) the geological aspect, which is concerned with the nature of the source of the earthquakes and the effects of earthquakes on rock and soil, (2) the physical aspect, which includes propagation of the waves in the earth, the recording of the earthquakes on seismographs and the interpretation of the seismograms (records) in terms of earth structure, and (3) the engineering aspect, which considers the damage to structures caused by earthquakes and the problems of earthquake resistant design.

CAUSE OF EARTHQUAKES

Explanations of earthquakes have been offered by mankind as far back as we know. Primitive peoples blamed earthquakes on animals which dwelt beneath the earth or seas—a mole in India, a whale in South America, a catfish in Japan, etc. Greek philosophers offered many explanations: subterranean tempests in caverns, storms in subterranean seas, etc. Early moderns (e.g., Robert Mallet) thought of collapse of caverns. Edouard Suess in 1874 pointed out that the centres of damage of earthquakes in lower Austria lay along lines and suggested that the shocks were due to fracture and slipping out of the earth's crust along faults. In 1875 he pointed out the same phenomenon in southern Italy. Since Suess's studies the vast majority of earthquakes have been attributed to slippage along faults, the grating as the two sides rub setting up earthquake waves. These are called tectonic earthquakes. Two other types are recognized: volcanic and collapse. A volcanic earthquake is one which may reasonably be attributed to volcanic action, so it must centre near a volcano and should be associated in time with some other sign of volcanic action. Such an earthquake affects only a small area although it may be very severe over this area. The collapse of limestone caverns or abandoned mines may cause slight tremors.

Some authorities have wished to classify deep focus earthquakes separately. James B. Macelwane suggested the name "Plutonic." These deep earthquakes, the existence of which was first proven by K. Wadati in 1928, have focuses at depths of greater than, say, 100 km (62 mi) and are known as deep as 700 km (435 mi). It is difficult to imagine ordinary faulting at great depths although the seismograms of such shocks suggest a source similar to shallow earthquakes by the geographical distribution of compressions and rarefactions in the first wave on the seismogram. If the source of a shock is along a vertical fault running north and south and if the break is one in which the west side jumps north and the east side south, then the first wave to reach stations in northwesterly directions and southeasterly directions is a compression, a motion away from the source. In the other two quadrants, northeast and southwest, the first motion at the stations is a rarefaction, a mo-

tion toward the source. Of course this first wave is followed by very many others, but it is the beginning which leads to conclusions about the faulting direction.

Elastic Rebound Theory—Once agreement was reached as to faulting as the cause of earthquakes, geophysicists became interested in the mechanism of faulting. After the San Francisco earthquake of 1906 Harry Fielding Reid put forth the elastic rebound theory. It was based on changes in the positions of triangulation monuments of the United States coast and geodetic survey as observed at intervals between 1851 and 1907. At the time of this earthquake the San Andreas fault broke for approximately 270 mi from Upper Mattole in Humboldt County to San Juan in San Benito County. The displacement was almost wholly horizontal, the coastal side moving north relative to the inland side, the maximum displacement was 21 ft. at the head of Tomales Bay. A thorough study was made of the shock, and a long report rendered by the State Earthquake Investigation committee. The elastic rebound theory born of this study may be stated as follows: Throughout a long period of time forces acting in the earth's crust, probably from below, tend to drag the coastal region of central and northern California northerly relative to the inland region. Eventually the strain in the rocks becomes so great that it can no longer be withstood and the rocks break. Just before the earthquake all the energy immediately to become earthquake motion is stored as elastic strain energy in the rocks. At the time of the break the rocks on either side rebound to a condition of no strain, the elastic energy being dissipated as earthquake waves and in heat through the agency of grating along the fault.

The elastic rebound theory merely pushes back the question of cause by saying that the strain accumulates slowly. This is highly reasonable, for most geologic processes are slow.

Cooling of the Earth—One of the oldest ideas advanced as a cause of accumulation of such strain is related to the cooling of the earth. Many scientists came to accept the idea that the earth is cooling from an original molten state. Computations suggest that the temperature at considerable depths (perhaps 700 km and below) has not changed perceptibly since the solidification of the earth's mantle (the outer 2,900 km [1,800 mi] above the core). Therefore the volume of this portion of the earth for which the temperature is constant remains constant. The hot rock just above the constant temperature and volume mass is able to flow plastically to accommodate its own shrinking and cooling about the constant sphere below it. The cooler surface layers, which are in radiation equilibrium with the sun, are then too large to fit the interior and must collapse. Faulting will accompany collapse. The scars then heal, and the process repeats itself with failure at intervals.

Isostasy—Another possible cause of slow strain is offered by the theory of isostasy. As early as 1749 Pierre Bouguer noted that the mountain mass of Chimborazo in Ecuador did not attract the plumb bob as much as he computed it should. Similar effects were later found all over the world. The phenomenon could only be explained by a deficiency of mass under the mountains. This led to statements of the theory of isostasy, namely, that at some moderate depth in the earth, probably less than 100 km, there is a level at which a pseudohydrostatic equilibrium exists, all columns of equal area of the earth's crust above this level have the same weight. According to Sir George Airy's statement of the theory, the continental masses are made of lighter rock which floats in the heavier rock of ocean basins. Mountains have roots, the lower profile of a continent is a magnified image of the upper profile. When mountains are eroded they tend to rise like an unloaded ship. Ocean bottoms sink when loaded with sediments. Such a process would explain a slow accumulation of strain in the crust of a vertical nature, and perhaps of a horizontal nature because of undertow.

Drifting Continents—There have been a number of advocates of the theory that the continents were once one mass which rifted apart and the several continents resulting drifted to their present positions. Foremost of these advocates was Alfred Wegener, the English translation of whose treatise appeared in 1924. Certain problems of similarities in flora and fauna on separate

continents are solved by this hypothesis but the lack of known forces of sufficient magnitude to accomplish the drift caused the theory to lose ground. Mountains pushed up on the forward borders of the Americas as they move west, with faulting and earthquakes are part of Wegener's picture.

Radioactivity—John Joly in 1915 developed an elaborate theory of cyclic effects of radioactive heat accumulated under the blanketing of continents and released when the material under the continents became so liquid that the small forces available could move them. The first of these is the Lotvos force, an equatorial force whose maximum is at latitude 45° where it has a magnitude of about one millionth of gravity. This force is due to the fact that the centre of buoyancy of a continent is below its centre of gravity. Thus the resultant upward force of the supporting medium is applied below the resultant downward gravitational force and since the direction of gravity is curved slightly in the plane of the meridian there is a tiny resultant force toward the equator. The other force exists because, bodily tidal friction retards the tidal bulges so that they do not lie on the line joining the centre of the earth and the centre of the moon. This results in a larger tangential force on the bulge nearer the moon than on the bulge further from it. Such a couple tends to slow down the rotation and if a continent was free to move might well drive it westerly. However it would be only about one ten-millionth as effective as the Lotvos or *Polibucht* force. According to Joly rock which has melted under continents solidifies under oceans (and vice versa). The mechanics are troublesome but the cyclic behaviour has a certain beauty.

Convection Currents—A number of theories which involve convection currents in the earth with resultant drag on surface rocks have been advanced. Some are quite local, others involve the whole mantle of the earth. Radioactive heating is generally called upon.

All of these theories involve mechanisms which would result in great strains slowly accumulated in the near surface rocks and offer ultimate sources for earthquakes.

Focus and Epicentre—The focus of an earthquake is defined as the point in the earth where the earthquake disturbance started. If the source was a fault break it is the point where the tear began. The source of the beginning of the first earthquake wave to be recorded on seismographs. The epicentre is the point on the earth's surface above the focus.

EFFECTS OF EARTHQUAKES

On Rocks and Soil—When the various types of elastic waves emanating from the fault arrive at the earth's surface they may cause considerable disturbance. Firm rocks transmit these waves with ease and they pass by the house built upon the rock without much effect. But shattered rock and soil on hillsides and uncon-

solid strata frequently cause fountains to burst forth in the epicentral region of a large earthquake. These fountains may flow for a few minutes or for days or weeks. Sometimes there may be merely a blowout of subterranean vapours. Sand is brought up from below. In the Salinas valley in 1906 one fountain brought up sand from a depth of 80 ft. In several of the great Indian earthquakes large areas of farming land were ruined by being so covered with sand. Spring fountains are often altered in the central region of a great shock. Steamboat springs near Reno, Nev., flowed muddy for days after the 1906 California earthquake.

Earth Lurches—In alluvial bottom land the soil is frequently so thrown about that cracks are left usually parallel to the river bed. The soil may be no lower after the shock than before, inertia rather than gravity is the important factor.

Wind Blows and Earthquake Fountains—Compression of under

ground strata frequently cause fountains to burst forth in the epicentral region of a large earthquake. These fountains may flow for a few minutes or for days or weeks. Sometimes there may be merely a blowout of subterranean vapours. Sand is brought up from below. In the Salinas valley in 1906 one fountain brought up sand from a depth of 80 ft. In several of the great Indian earthquakes large areas of farming land were ruined by being so covered with sand. Spring fountains are often altered in the central region of a great shock. Steamboat springs near Reno, Nev., flowed muddy for days after the 1906 California earthquake.

Earth Lurches—Large masses of dry, loose rock on mountain slopes lie frequently near their natural angle of repose and an earthquake disturbs this critical equilibrium resulting in avalanches. One historic example was the avalanche of 1906 in the Santa Cruz mountains. This slide near Grizzly peaked flowed down a canyon moving down many acres of redwoods. Some of these trees continued to stand at an angle to the vertical.

Earth Slumps—On hillsides during the rainy season the regolith or soil and subsoil, is frequently water soaked. Even without an earthquake slips of this wet soil often occur, a portion of the hill side slumping down with some rotation on a horizontal axis. Earthquakes greatly promote slumping.

Earth Flow—On occasion the shaking of an earthquake causes water to gush out of a hillside and the stream may carry great quantities of sand and wet soil down the hill in a river of mud. An example was the mud flow at Mt. Olivet cemetery, San Francisco, Calif., in 1906. Ninety thousand cubic yards of soil flowed 900 yd in three minutes. The greatest depth of the flow was 13 ft.

Earthquake Sounds—As will be noted in the paragraph on seismic waves the first waves of an earthquake (called P waves) are compression rarefaction waves. If the frequency of these waves is in the audible range we call them sound. Some earthquakes are heard by some people usually in the region where the shock is sharp. These sounds are of low pitch, near the limits of the human ear so that not all people hear them. Animals are frequently alerted just before a shock and it has been suggested that they may hear the waves before men feel them. At the time of the 1906 earthquake a farmer near Santa Rosa, Calif., observed his cows milling about the corral. He shouted to his son near the corral asking the cause, but before the boy could answer the father felt the earthquake.

Effects on the Sea—The effects of an earthquake on bodies of water are classified under three types (tsunamis, sea quakes and seismic seiches).

Tsunamis—These are gravity waves set up in the ocean by some disturbance of the sea bottom. The disturbance may be a vertical displacement of a fault on the sea floor or a submarine landslide caused by severe shaking. A great depression or (occasionally) a great mound of water is thus suddenly created over a large area. This disturbance of equilibrium starts a huge oscillation, and the long low waves set up propagate away from the source. Their theoretical speed is \sqrt{gh} where g is the acceleration of gravity and h the water depth. These waves may be more than 100 mi long and only a few feet high at sea. Thus they are not observed by ships at sea. As the waves approach shore, and the water shallows, they pile up particularly in V-shaped bays. The Sanriku (Japan) tsunami of 1933 at Atsumi had a height of 3 m at the mouth of the bay and 23 m at the head of the bay. The earlier Sanriku tsunami in 1896 attained a maximum height of 93 ft in Miyako bay. Six to eight waves were observed at intervals of 7 to 34 minutes. A schooner was carried 300 yd inland. It took this tsunami 10 hr 34 min to reach the tide gauge in San Francisco, the average speed was about 450 mi per hour. There it recorded as a wave of period 15 minutes indicating a wave length of a little over 100 mi at sea. The tsunami accompanying the Iquique (Chile) earthquake of 1877 recorded on the gauge at Hakodate, Japan, 10,300 mi away, with a height of 8 ft. The tsunami following the earthquake of April 1, 1946, which centred on the slopes of the Aleutian trench travelled to Honolulu, a distance of 2,241 mi, at an average speed of 490 mi per hour. It did great damage in the Hawaiian Islands. Tsunamis are sometimes set up by storms or sudden variation in barometric pressure.

A SEISMOGRAPH, AND ITS RECORD OF AN EARTHQUAKE

1 Section of a seismograph record of the earthquake in Chile 1922. 2 A seismograph. The horizontal pendulum, carrying a steady mass weighing 220 lb., registers earthquake motion (magnification 80-100) on smoked paper which rolls upon a drum, the paper being marked in convenient units of time. One such instrument is set in N-S direction to record E-W motion and a second E-W to record N-S.

Sea Quakes—The compression refraction or P waves from the earthquake focus or source are refracted into the water from the earth. The disturbance of the water as these waves propagate is called a seaquake. They were strong enough to sink fishing boats in the 1896 Sanriku quake. The sea quake accompanying the great Lisbon earthquake of 1755 opened seams in the decks of ships. Masts have been brought down by them. In shocks of less magnitude the vessel shakes as if it had run into a submerged object. Sea quakes rattle the sea's surface in a short chop and kill or stun fish.

Seismic Seiches—A body of water landlocked, or nearly so has a period or periods of natural oscillation peculiar to its configuration. Severe shaking of the earth or the arrival of a tsunami may set a bay or lake into its natural oscillation which may continue for several days. The great Lisbon (Portugal) earthquake of 1755 was famous for the seiches which it produced. Even rivers were greatly disturbed. As far away as the island of Corsica most of the rivers overflowed their banks. Loch Lomond in Scotland oscillated for an hour, the rise being about 2 ft. The tsunami from the Iquique earthquake of 1877 set San Francisco bay into oscillation for two days.

T Waves—There is a low velocity sound channel in the ocean at a depth of about 400 fathoms at certain seasons in certain latitudes. Small explosions in the channel can be detected by receivers in the channel at vast distances. Many West Indian earthquakes get energy into this channel, and these waves in the water are able again to enter the land and record on seismographs at stations near the Atlantic coast. Many Hawaiian earthquakes send waves through this channel to seismographic stations in northern California, often there is more energy in this water channelled wave than in the earth waves. It is necessary presumably that favourable conditions exist where the earth waves enter the water and where they leave it. The southern California seismographic stations do not receive the T waves from Hawaii. The periods of T waves are 0.7 sec or less. They are a particular kind of sea quake wave but may be classified separately, perhaps, because they (1) are observed on land and (2) propagate to great distances.

Foreshocks and Aftershocks—Every great earthquake is followed by a succession of aftershocks as the earth settles down. There are hundreds strong enough to be felt in the first few days after a big earthquake. They may last for years. It is exceedingly rare to have within the period of a few months (or even years) more than one great shock in a given locality. Two exceptions which can be cited in the United States are the three great New Madrid, Mo., earthquakes of the winter of 1811-12 and three Helena, Mont., earthquakes of 1935.

Foreshocks are smaller earthquakes which occur before a big one, say within a month, and have approximately the same centre as the great shock. Not all large earthquakes have foreshocks. There are none reported in the *Report of the State Earthquake Investigation Commission* for the San Francisco earthquake of 1906. For the Long Beach earthquake of 1933 one foreshock, 41 hr before the main shock, was reported by Harry O Wood.

Intensity Scales—The intensity of an earthquake is rated by its effects on rock and earth, on man and on his works. The greatest intensity is demonstrated by great cracks in the earth and landslides, accompanied by ruin of buildings, bridges, etc. The least intensity is that felt only by a few experienced observers who were sitting or lying down at the time. Between these extremes various scales have inserted different numbers of divisions. Such a scale is the modification by Harry O Wood and Frank Neumann of the older Mercalli scale (*Bulletin of the Seismological Society of America*, 21 277-283 [1931]).

Modified Mercalli Intensity Scale of 1931 (Abridged)

- I Not felt except by a very few under especially favourable circumstances
- II Felt only by a few persons at rest, especially on upper floors of buildings. Delicately suspended objects may swing
- III Felt quite noticeably indoors, especially on upper floors of buildings, but many people do not recognize it as an earthquake. Standing motor cars may rock slightly. Vibration like passing of truck. Duration estimated

- IV During the day felt indoors by many, outdoors by few. At night some awakened. Dishes, windows, doors disturbed, walls made cracking sound. Sensation like heavy truck striking building. Standing motor cars rocked noticeably.
- V Felt by nearly everyone, many awakened. Some dishes, windows and so forth broken. A few instances of cracked plaster, on unstable objects overturned. Disturbance of trees, poles, and other tall objects sometimes noticed. Pendulum clocks may stop.
- VI Felt by all, many frightened and run outdoors. Some heavy furniture moved. A few instances of fallen plaster or damaged chimneys. Damage slight.
- VII Everybody runs outdoors. Damage negligible in buildings of good design and construction, slight to moderate in well-built ordinary structures. Considerable in poorly built or badly designed structures. Some chimneys broken. Noticed by persons driving motor cars.
- VIII Damage slight in specially designed structures, considerable in ordinary substantial buildings with partial collapse, great in poorly built structures. Panel walls thrown out of frame structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned. Sand and mud ejected in small amounts. Changes in level water. Persons driving motor cars disturbed.
- IX Damage considerable in specially designed structures, well designed frame structures thrown out of plumb, great in substantial buildings, with partial collapse. Buildings shifted off foundations. Ground cracked conspicuously. Underground pipes broken.
- X Some well built wooden structures destroyed, most masonry and frame structures destroyed with foundations, ground badly cracked. Rails bent. Landslides considerable from river banks and steep slopes. Shifted sand and mud. Water splashed (sloped) over banks.

FIG 1—ISOSEISMAL MAP OF THE EARTHQUAKES OF OCT 2 1934

- XI Few if any (masonry) structures remain standing. Bridges destroyed. Broad fissures in ground. Underground pipe lines completely out of service. Earth slumps and land slips in soft ground. Rails bent greatly.
- XII Damage total. Waves seen on ground surfaces. Lines of sight and level distorted. Objects thrown upward into the air.

In order to rate the intensity of an earthquake a seismologist may either (1) visit the localities in which the shock was felt to make inquiries and observations or (2) he may send questionnaires into the region. In 1928 the United States coast and geodetic survey commenced a program of collecting such questionnaire reports. A number of blank questionnaires are given to each prospective observer, and he is asked to send one in on the occurrence of a shock. Postmasters form the backbone of the reporting system, but a great many other reporters have been

added. The questions are based on the above scale. Difficulties in the assessment of the intensity from the reports usually lie in a disparity between effects on people and effects on inanimate objects, e.g., some people are frightened more easily than others. In general, a man who has once felt a great earthquake is more frightened by small ones than is an inexperienced person. Familiarity does not breed contempt for earthquakes. Having assessed the intensity the seismologists plot on a map of the area the intensity number for each town. They then draw closed curves bounding the areas corresponding to each intensity. These curves are called isoseismal curves. They are frequently oval in shape indicating a linear source or a vertical plane source. These central ovals are frequently along a known fault and give confirmation of the theory that faults are the source of earthquakes.

GREATER EARTHQUAKES

Lisbon, Portugal—Probably the most famous of all earthquakes is that which destroyed Lisbon on Nov. 1, 1755. There were three great earthquakes (the first was the largest) at 9:40 A.M., 10 A.M. and 11:00 A.M. The main shock lasted six to seven minutes, an unusually long duration. Within six minutes at least 30,000 people were killed, all large public buildings and 1,000 dwellings were demolished. It was a church day and great loss of life occurred in the churches. A fire followed which burned for six days. A marble quayside in the river bottom slipped into the river bottom filled with people. Alexander von Humboldt stated that the total area shaken was four times that of Europe. Charles Davison concluded that the great damage in places as far apart as Lisbon, Tez (Morocco) and Algiers indicates more than one source. There was some damage to buildings in the Spanish cities of Seville, Cordova and Granada. In Africa Fez and Meknes were badly damaged and even in Algiers, 700 miles east damage was reported. Portions of the coastal cliffs near Lisbon fell into the sea and there were landslides and cracks throughout the mountains.

The Lisbon earthquake was remarkable for its effects in water. Seams opened in the deck of a ship near Lisbon during the resulting sea quake. It was reported that 40 leagues west of Cape St. Vincent a man was thrown 15 ft vertically from the deck of a ship. Critical students, however, do not accept this story. The tsunami at Lisbon consisted of three large waves 15 to 40 ft high. At Cadiz Spain it was 60 ft high. It took the tsunami 10 hr to reach Martinique (7,540 mi) where it was 12 ft in height.

New Madrid, Mo.—The greatest earthquakes on record in the United States are those which centered near New Madrid in southern Missouri in 1811 and 1812. There were three great shocks in the series on Dec. 16, 1811, on Jan. 20, 1812 and on Feb. 7, 1812. There were innumerable others of lesser intensity as is usual. Between Dec. 16, 1811, and March 16, 1812 there were 1,874 of these shocks strong enough to be felt in Louisville, Ky., 200 mi away. 8 were classed as severe. The region of New Madrid was sparsely settled and the reports are not such that observers can differentiate between the effects of the three great shocks, so they must be discussed as one. The tract of greatest shaking comprised about 40,000 sq mi. southerly from New Madrid including parts of eastern Tennessee and northwestern Arkansas. In this region the soil was disturbed by the shaking. A region 150 mi long and 40 mi broad later called the "Sunken Country," sank from 3 to 9 ft, and river water rushed in. Ridges left by waves were seen in the soil, the soil broke open and wind and sulphurous vapours were ejected. Forests were ruined by being overthrown or having soil shaken away from the roots of the trees, low domes and depressions were formed in the soil. Reelfoot Lake in Tennessee was torned by these shocks. The earthquakes were strong enough to shake down chimneys in Cincinnati, O., 400 mi away. (The 1906 California earthquake was not felt farther than 300 mi to the west.) The New Madrid shocks were of intensity IV on the above scale in Washington, D.C., 500 mi away. They were felt in Canada and on the Gulf coast and as far away as the headwaters of the Missouri and the Arkansas rivers.

Charleston, S.C.—On Aug. 31, 1836 at about 9:21 P.M., oc-

curred a great earthquake which centred near Charleston, S.C. On account of the great area over which it was felt it must rank with the great earthquakes of the world, and as the second largest in the United States. It was felt 950 mi away on the upper Mississippi and in Bermuda. In the region to the west of Charleston, near the villages of Woodstock and Rintowles, the soil was disturbed. The area so disturbed was not more than 600 sq mi, small indeed compared to the similarly disturbed area of the New Madrid shocks, although the total area over which these earthquakes were felt was approximately the same. In Charleston the earthquake was felt by people for about 70 sec. Although no buildings were entirely demolished the damage to property was estimated at \$5,000,000 and 27 people (out of 50,000) were killed. The damage was greatest on filled ground although buildings on such ground which were built on piles stood up well.

California (1906)—On April 18, 1906, at about 5:12 A.M., the San Andreas fault broke for a length of approximately 270 mi from Upper Middle in Humboldt county to San Juan in San Benito county. This break was accompanied by a great earthquake which was felt from Los Angeles on the south to Coos Bay, Ore., on the north a distance of about 750 mi. To the east it was felt as far as Winnemucca, Nev., about 300 mi. The fault break was the longest on record. The greatest displacement was horizontal and amounted to 21 ft at the head of Tomales bay. The vertical displacement was minor and was observed only to the north where it may have been 2 or 3 ft. The main shock lasted about 40 sec. Earthquake damage was great in many cities near the fault. San Francisco, San Jose, Salinas, and also at Santa Rosa about 20 mi from the fault. Regularly the most damage occurred on man made filled ground and the least on rock. Cities on natural valley fill suffered more than cities on rocky hill slopes. But the greatest loss of property resulted from the fire which followed the shock in San Francisco.

Fires are frequently a consequence of an earthquake. A city in an earthquake region must take great care to have several sources of water supply and to be ready for the day. The number of lives lost in this earthquake was estimated at 700. John R. Freeman estimated property loss caused by the shock at \$20,000,000 in San Francisco, and \$4,000,000 elsewhere, and fire damage in the city at \$400,000,000.

Tokyo, Japan (1923)—At noon on Sept. 1, 1923, occurred a great earthquake which left Tokyo and adjacent cities in ruins. The violent motion lasted only half a minute. In Tokyo alone 68,000 people were killed of whom 40,000 were burned by fire in the yard of the military clothing depot. Throughout the area affected, the death toll was 100,000, while 43,000 remained missing. Property loss was estimated at \$2,500,000,000. Fifty per cent of the brick buildings collapsed and 10% of those of reinforced concrete. One per cent of the dwellings collapsed in Tokyo, but 700,000 houses burned. The damaged area was around Tokyo and Sagami bay. The shaking of the soil was so great that potatoes were thrown out of the ground at some places. The epicentre of the shock was located beneath Sagami bay (the outer portion of Tokyo bay). Detailed surveys indicated great changes in the depth of the bay, these were differences between depth measured just after the earthquake and depth observed about ten years before. The maximum increase in depth was 600 ft, and the maximum decrease was 820 ft. Many Japanese seismologists thought that these changes all occurred at the time of the earthquake and indicated huge faulting. On land about 15 small faults broke on both sides of the bay. The longest was 13 mi, and the maximum displacement was 6 ft in vertical. The faults did not have a common direction. Although the epicentral shaking was extremely violent the quake was not felt much more than 400 mi from its source. The accompanying tsunami was 36 ft high at Atami, on Sagami bay where it destroyed 155 houses and killed 60 people.

GENERAL DISTRIBUTION OF EARTHQUAKES

It is well known that earthquakes occur more frequently in some parts of the earth than in others. Count Ferdinand Montessus de Ballore pointed out that most have occurred in two great-

circle belts the one about the Pacific ocean and the other including the Alps, the Himalayas and the West Indies. Among exceptions are the New Madrid and the Charleston shocks described above. There is scarcely a state in the United States that has not experienced some earthquakes.

According to Ballore slightly more than half the earthquakes in the historic record have occurred in the Alps Himalayas great circle zone. According to Beno Gutenberg and Charles F. Richter about 80% of the seismic energy released on the earth is released in the circum-Pacific belt. There is an interesting relationship between the positions of the focuses of deep and shallow earthquakes in regions where both occur. For example, there are shallow earthquakes (depth less than 50 km) with epicentres off the Chilean coast, intermediate depth shocks (depth between 50 km and 200 km) near the coast and under the Andes and deep earthquakes (depth 200 km to 700 km) under the Argentinian plain. In parts of the Japanese region there is a similar distribution, many of the deep shocks centring under the Japan sea and Manchuria. The distribution of earthquakes was completely discussed in *Seismicity of the Earth* by Gutenberg and Richter in 1949.

FIG. 2—TRACING FROM NORTH-SOUTH COMPONENT WILIP GALITZIN SEISMOGRAPH, BERKELEY OF THE TEXAS EARTHQUAKE OF AUG. 16, 1931. EPI-CENTRAL DISTANCE ABOUT 800 MI.

EARTHQUAKE WAVES

Beginning about 1880 a new interest in earthquake waves was aroused, particularly in Japan where John Milne and his coworkers at Tokyo university began to build seismometers and study earthquake motion. These men equipped their seismometers with writing devices and began a careful study of the records, called seismograms. A little later Emil Wiechert in Germany built new seismographs and directed an institute at Göttingen university from which many fundamental papers on seismology appeared. Prince Galitzin in Russia embarked on a similar program.

It was found that the vibrations emitted from the source of an earthquake travel through the earth by many different paths and as several different types of wave motion. Thus the seismogram written at a distant station shows a great many groups of waves, which arrive at different times. On the seismogram the motion of a pendulum relative to its support is written on a recording drum which rotates, so the recorded motion is spread out as a function of time. (See SEISMOGRAPH) Fig. 2 and 3 show tracings of two seismograms. The first shows clearly two groups of waves early named P and S for primary and secondary. These two

groups and their reflections as discussed below, were named the preliminary tremors of the earthquake while the larger waves following were called the principal portion. They were divided into two groups L, for long and M, for maximum. Another still longer wave preceding L was later called G, for Gutenberg who first called attention to it.

Preliminary Waves—R. D. Oldham suggested that P and S waves were perhaps the longitudinal and transverse waves respectively for which the theory of waves in an elastic medium called, and such indeed they proved to be. The mathematical theory of elasticity had indicated that a blow struck an elastic body, say a portion of the earth's rocky crust would result in a sudden strain which was a compound of change in volume and change in shape. The initial strained portion of the rock would vibrate about its initial form as it recovered equilibrium and would impart this vibration to neighbouring portions of rock. Thus waves would be propagated out from the centre of the disturbance. But the theory pointed out that the change in volume strain would propagate more rapidly than the change in shape, so that in a homogeneous isotropic solid with no boundaries (to reflect, refract or support surface waves) just two waves would arrive at any point. As the first of these passed the point, the medium would change volume only, the particles of the medium would vibrate back and forth in the direction of the path of the wave (i.e., longitudinally), the medium would experience compression and rarefaction. These are P waves. As the second wave passed, the medium would experience change in shape only or shear, the particles of the medium would vibrate back and forth at right angles to the path of the wave or transversely. These are S waves. Milne and other early workers obtained the times of arrival of P and S at many seismographic stations at different distances and plotted them on a "travel time curve," a graph on which epicentral distance around a great circle of the earth was plotted as abscissa and the time of travel of the wave as ordinate. They found the travel time curves of both P and S to be concave downward, i.e., the farther the wave is from the epicentre the greater is its apparent surface speed. This showed at once that P and S do not travel along the earth's surface. If they did, the observed surface speed would not increase with epicentral distance although it would vary somewhat with the nature of the surface rock. For the speed of P and S waves are known from the theory of elasticity to be respectively

$$V_p = \sqrt{\frac{\kappa + \frac{2}{3}\mu}{\rho}} \quad \text{and} \quad V_s = \sqrt{\frac{\mu}{\rho}}$$

where κ is the coefficient of incompressibility or bulk modulus of the transmitting medium, and μ is its coefficient of rigidity or shear modulus, ρ is the density. Next was considered the possibility that P and S travel along chords of the earth as they would be expected to do if their speeds were constant throughout the earth's body. Curves drawn with travel time as ordinates and chord distance from focus to station were still concave down, indicating the speed greater on deeper chords. So the speeds of P and S increase with depth, and the rays or wave paths must then be convex downward. P and S penetrate into the earth and are refracted to the surface. The seismologist studies them after this passage and draws conclusions as to the nature of the earth's interior. As above, the first contribution of seismology to the knowledge of the earth's interior was the knowledge that the speeds of P and S increase with depth, the rays or wave paths must then be convex downward. This was not to have been expected a priori, for it was known that the mean density of the earth was about

FIG. 3—TRACING FROM EAST-WEST COMPONENT BOSCH OMORI SEISMOGRAPH, BERKELEY OF AN EARTHQUAKE CENTRING NEAR THE AZORES ON NOV. 25, 1941. EPICENTRAL DISTANCE IS ABOUT 5,000 MI. PP and SS represent waves reflected at the earth's surface about halfway between the source and the recording station (see Fig. 4). PPP and SSS have been reflected twice.

55 whereas ρ is a fair figure for the mean density of surface rocks. So it was known that density increased with depth and from the equations given above for the speeds of P and S one might have expected the increase in density to cause a decrease in speed. Laboratory experiments on rocks, particularly at the geophysical laboratory of the Carnegie Institution of Washington and at Harvard have early shown that when a rock is compressed the elastic constants μ and λ increase more rapidly than does the density and that rocks of higher density invariably have elastic constants much higher also, so that the quotients $\frac{\lambda + \frac{2}{3}\mu}{\rho}$ and $\frac{\mu}{\rho}$ are higher for denser rocks.

For epicentral distances larger than $\approx 10^\circ$ (360° being the circumference of the earth) there are groups of waves observed between P and S which have been shown to be reflections of P at the earth's surface, about halfway between the epicentre and the recording station. Similar reflections of S are observed between S and G, the first surface wave, in fig 3 shows. For epicentral distances greater than 103° both P and S are very weak. The rays emerging at 103° have penetrated the earth to a depth of about 2 900 km, or 1 800 mi (the radius of the earth is about 3 770 km or 3 955 mi). So, at this depth in the earth something blocks P and S. This is the "core" of the earth. The speed of P waves drops sharply as they enter the core (see fig 4). Beyond 103° the small P and S observed have straight line travel time curves, indicating that they are diffracted around the core boundary. But at 142° a new longitudinal wave emerges in two parts. These waves are called P₁ and P₂ and represent P waves which have traversed the core. The speed of P waves drops suddenly at the core boundary so that the core acts for P waves as a spherical lens with much aberration. This results in a "shadow zone" for P between 103° and 142° . The phenomenon at 142° and beyond is somewhat analogous to the caustic surface of optics. The variation of the speed of P within the core in general increase with depth complicates the matter. S waves have not been observed to traverse the core. This indicates a fluid core if we understand by fluid the state which will not support shearing stresses. P and S waves are both reflected from the core and these reflections recorded on seismograms. When either P or S strikes a discontinuity there are in general four waves set up: P and S reflected and P and S refracted. Snell's law holds of course, i.e., the sine of the angle of incidence is to the sine of the angle of refraction (or reflection) as the speed of the incident wave is to the speed of the refracted (or reflected) wave. So we record waves incident on the core as S, refracted into it as P, refracted out of the core as S (or as P). Some of the energy in P through the core is reflected back into the core at its boundary while some is refracted out so we record waves which have two branches in the core. The possible number of paths is large. Seismograms are complicated.

It is probable that there is an "inner core" (i.e., that the properties of the core change rather sharply at a depth of about 5 000 km or 3 105 mi). This would explain the existence of some P waves observed in the shadow zone. Some have even suspected that the inner core may not be fluid.

We have just seen that seismology has established the existence of a core of the earth which appears to be fluid at least in its outer structure. Near the earth's surface other discontinuities in the earth's structure have been indicated. In 1909 A. Mohorovicic reported a Kupa valley earthquake on the records of which it was seismographic stations he observed two P waves. This phenomenon of more than one P wave near the epicentre (viz zero to 500 km) was soon recognized by all seismologists. Two or three P waves of different speeds are observed wherever there is a close network of seismographic stations in a region of earthquakes. Each of these speeds indicates transmission in a different type of rock. The waves are observed in all directions from the epicentre, so the rocks must be symmetrically disposed in horizontal layers. The speed of the first P wave very near the epicentre (within 100 km) is 5.6 to 6.2 km per second. This wide variation of speed seems to be due to the considerable variation in the surface rocks—observations of near earthquakes and explosions offer considerable scatter on the time distance graph. At a depth of about

10 km many studies have shown a fairly abrupt change in the speeds of P and S. The layer above 10 km depth has frequently been called the granitic layer. Below 10 km the speed of P is between 6 and 7 km per second in a layer which extends to depth of 30 to 40 km in most regions. This layer has been called basic or basaltic. At its bottom there is a quite sharp boundary called the Mohorovicic discontinuity. Just under it the speed of P is 8 km per second. It is deeper under mountains. In California P waves travelling just below the Mohorovicic discontinuity from Coast range earthquakes are blocked by the root of the southern Sierra Nevada and are not recorded at the Owens valley seismographic stations. Thus seismology has been able to prove the existence of a mountain root, a protuberance of lighter surface rock into the heavier mantle rock. Such roots had long been considered necessary by proponents of the Airy concept of the theory of isostasy—the theory that continents and mountains float effectively in the underlying mantle rock.

The existence of the Mohorovicic discontinuity is not questioned. However the type of variation in the layer above it is a moot question. Some seismologists consider the variation of the speed of seismic waves with depth in this region to be continuous. Some want it to decrease and then increase, and some to have it divided into two layers as described above.

FIG. 4—(LEFT) SCHEMATIC GREAT CIRCLE SECTION OF THE EARTH SHOWING THE CORE. STATION S_1 RECEIVES P AND S WAVES AND THEIR REFLECTIONS WITHOUT DISTURBANCE FROM THE CORE. STATION S_2 CAN ONLY RECEIVE DIRECT P AND S WAVES. IT RECORDS A P WAVE REFRACTED THROUGH THE CORE.

FIG. 5—(RIGHT) THE PATHS OF THREE WAVES OBSERVED NEAR THE SOURCE OF AN EARTHQUAKE ARE SHOWN AS DOTTED LINES. THESE WAVES INDICATE THAT THE EARTH'S SURFACE IS LAYERED.

Under the oceans the Mohorovicic surface is much higher than under continents, its depth being only 5 to 10 km. The material above it, under a few kilometres of sediments, is rock of the same nature as that of the lower part of the continental layer. The lighter rocks of the granitic layer are absent.

Beneath the surface layers is the mantle of the earth which extends to the core. Possible discontinuities in the mantle have been a matter of debate among seismologists. So earthquake seismology has shown the earth to have a core and to have an outer ring. The methods of computation of the variation of speed of P (or S) with depth in the earth are not simple, some are very complex.

Surface Waves—The "principal portion" of the seismogram records large waves of three kinds, called G, L and M. The mean travel time curves of each is a straight line, but there is much scattering. For these waves travel around the surface of the earth, as the straight-line travel time curve indicates, and the surface rocks of the earth are varied. These surface waves travel faster under ocean basins than along continental paths. The fastest surface waves are the G waves. These are shear or transverse waves with no vertical component. Their theory was given by A. E. Love. Their existence requires an increase of speed with depth. The M wave approximates the theoretical wave of Lord Rayleigh. As a Rayleigh wave passes a particle on the earth's surface, it moves in an ellipse in the plane containing the focus, the particle and the earth's centre. The motion is retrograde and the major axis is vertical. The L waves have no theoretical counterpart. They have a vertical component. By observing the dispersion of Love and Rayleigh waves the theory allows certain conclusions about

the surface structure of the earth. The ratio of vertical to horizontal motion in Rayleigh waves has been used for the same purpose. Longer surface waves penetrate deeper into the earth where the elasticity is greater. Therefore they travel faster and dispersion results. By the 1950s, surface waves with periods as great as seven minutes had been observed and seismographs were being designed to record longer periods. Waves of such great length involve vibration penetrating deep into the mantle to give further information about the earth's core. It had become apparent that the spectrum of a great earthquake is very broad. The limits in wave lengths possible depend at the one end on molecular dimensions and at the other end on the dimensions of the earth.

LOCATION OF EPICENTRES

The methods of the seismologist for locating the epicentre of an earthquake are of much interest to the public. For the earliest workers, the epicentres were the centres of the region of greatest damage. They built rough travel time curves for S and P, then the method of successive approximations so common in science was used. Epicentres were located using the time intervals between S and P from the graph to get distances. When these distances from various stations did not reach to a common point on the earth, the S and P curves were readjusted. It was not long until the S and P curves were so refined that the distances did agree. The simplest method of locating epicentres is called the S-P method. Over the years tables were prepared to give the epicentral distance as a function of time interval between S and P. So the seismologist soon has the distance from his station. If he can obtain the distance from two other stations, he is able to locate a point on his terrestrial globe and he has his epicentre. From the records of one station alone he may sometimes get direction as well as distance. He knows that the P waves are longitudinal. The pier on which the seismograph sits vibrates back and forth nearly in the direction which the P wave has travelled. A good record of the start of P on the three components, east-west, north-south and vertical seismographs, will allow the computation of direction of the epicentre. A more accurate method used in special studies involves the use of the arrival time of P at many stations and a least square adjustment.

SEISMIC PROSPECTING

After World War I interest was roused in investigating the very superficial part of the earth by seismographs and artificial explosions. The primary purpose was to map underground structure in regions considered to have oil bearing possibilities. Ludger Mintrop in Germany was the first to use the method successfully. The first work was of the type called "refraction shooting." A charge of explosive was fired and recorded on seismographs distributed along a line which was often several miles in length. Near seismographs registered waves which had travelled almost a straight line from the shot. At successively large distances waves were recorded which had travelled just below boundaries between strata at successively greater depths. The depths to these boundaries could be computed from the travel-time curves. What interested the prospectors were irregularities in these boundaries—highs or anticlines in the buried structure or salt domes rising through them, or faulting which might result in traps. A later development was the use of waves reflected at the underground boundaries. Smaller explosive charges were used and the seismic receivers were placed not far from the shot (distance measured in hundreds of feet). The reflection method reached a high degree of development in the 1930s, only P waves were used and only vertical component seismometers (see also GEOPHYSICAL PROSPECTING).

ENGINEERING ASPECTS OF SEISMOLOGY

There have been two schools of thought among engineers about the general theory of earthquake-resistant design. One of these is the "rigid" school, which holds to the thesis that a building should be as rigid as possible. In an ideal, perfectly rigid building the top and bottom would move exactly the same amount at the same time. Such motion would put large stresses into the frame which would be designed to support these stresses. The

other school, that of "flexibility," holds that a building should be able to sway during the motion. For example, in an extreme case a building built of vulcanized rubber like an automobile tire would not be damaged by a large shock although its contents would undoubtedly suffer. The stresses within the structure would probably not mount so high as in the rigid building. For very rapid ground motion the top might remain almost stationary. It must be noted that flexibility does not mean flimsiness or poor construction.

In practice, of course, builders are limited by building materials available. They cannot even approach the ideal cases cited above. Steel and brick and concrete for large structures and wood for dwellings limit rigidity and flexibility to a small range. Proponents of flexibility have suggested a first floor supported principally by columns which would allow a fair relative motion between foundation and higher floors. The rigidity advocates would thoroughly brace all parts of the structure. K. Suyehiro recommended rigid buildings on soft ground and flexible buildings on rock. His idea was that the small displacements possible in rock might be absorbed by lower floors but the large amplitudes possible in soil could not be so absorbed.

About 1928 the United States coast and geodetic survey embarked upon a program of accumulating seismological data of significance to engineers. An important part of this program was information on the effects of all earthquakes felt in the United States. Postcard questionnaires based on the modified Mercalli scale of earthquake intensities were placed in the hands of as many people as possible in seismic areas, particularly in California. Moreover, after any large shock a survey representative visited the scene of greatest effect and wrote a report.

In addition the survey undertook an instrumental program. For many years it had been assumed that the damage caused by an earthquake would be proportional to the maximum acceleration of the ground. From observation of the overthrow of monuments, assuming the earthquake force to be a continuing one rather than quickly changing in magnitude and direction, early seismologists had correlated the intensity from the scales of intensity with acceleration. From these old correlations it appeared that a horizontal acceleration of one tenth gravity might be accompanied by almost total destruction. A rule of thumb had been developed in some earthquake countries such as Japan that a building should be constructed to withstand at any level a steady horizontal force of one tenth its weight above that level. That this would make the building earthquake-resistant was not questioned but it was expensive. So the United States engineers wished to have the maximum acceleration observed instrumentally in California to see if one tenth gravity was not too high. The survey designed insensitive seismographs which would be able to record the large motions of strong earthquakes and set them up first in California and then more widely. Such instruments recorded the Long Beach earthquake of 1933, the Imperial valley shock of 1940 as well as many others. To the surprise of all, a maximum acceleration of three tenths of gravity was found not uncommon. But it accompanied waves of period around three tenths of a second or less, i.e., the forces it set up in the building changed direction very frequently. Buildings designed and constructed to withstand a steady force of only a few per cent of gravity stood up quite well. From this it became clear that the damage is not proportional to the maximum acceleration. It depends also on how often the acceleration changes directions, or on the period of the waves. The program of the coast and geodetic survey also included the measurement of the natural periods of vibration of many buildings with a view to determining how these periods may be related to later earthquake damage. Shaking-table investigations on models of buildings were carried out particularly by L. S. Jacobsen of Stanford university, Stanford, Calif. This type of work enables the prediction of maximum stresses to be expected within the structure. A large platform is caused to vibrate with a motion such as that of the earth in, say, the Long Beach earthquake. This motion is obtained from the strong-motion seismographs mentioned above. On the platform is constructed to scale a model of a building. Others have suggested arrays of pendulums to motion similar to that of

particular earthquake and from their responses concluded something about stresses to be expected in buildings having the same free periods as the pendulums

disc which is not illuminated by the sun is illuminated by earthshine analogous to moonlight. It is a familiar observation that when the moon is a crescent the earthshine is powerful enough to make the whole disc easily visible. The phases of the earth and moon are complementary so that the earth is near "full" when the moon is near "new" and the earthshine is then strongest

EARTHSTAR (Gaster), in botany a kind of puff ball

(gaster), with a distinct outer coat which on separating from the

inner, splits into several divisions, which become reflexed and spread like a star. The inner coat enveloping the spores is supported, like a ball, with or without a stalk on the upper face of the star. The spores generally escape by a distinct aperture which appears in the top of the ball. There are several species in Britain, found on the ground or on decaying leaves. They are generally distributed throughout America. (See FUNGI)

EARTHWORM The term has been applied to include all terrestrial oligochaetes (see ANNELIDA), but is usually restricted to larger forms belonging to the order Oligochaeta of which there are nearly 2,200 described species. Earthworms vary in size from small forms about 1 in. in length, such as the tree worms (e.g., *Bimastus constrictus*) which live under rotting wood and bark, to very large species that have sometimes been mistaken for snakes. *Rhinodrilus jafneri*, a South American form, may be 6 ft. 10 in. (2100 mm) long and nearly 1 in. (24 mm) thick, while the giant Gipsyland worm (*Megascaphodes australis*) is said to exceed 7 ft. when fully extended. Some earthworms are palid while many are red brown or purple, all are more or less slender. A few are more brightly coloured, such as the green-worm (*Allolobophora chlorotica*) of Europe and North America, a Philippine species (*Pheretima opheodes*) is mottled with bright blue. The majority, when irritated, discharge a colorless fluid which may have an unpleasant odour, as in the brandling (*Eisenia foetida*), or be phosphorescent. Mature earthworms have a glandular girdle, the clitellum. They are hermaphrodite, but cross-fertilization is effected by reciprocal copulation, eggs are deposited in cocoons secreted by the clitellum and slipped off at the anterior end of the worm. Sexual maturity is reached within six months or a year, depending on the time of hatching, and recurs annually thereafter, toward the end of the rainy season or in autumn and early winter, perhaps again in late spring. European Lumbricidae have been kept for many years in captivity.

The majority of species have a very restricted geographical distribution, owing to their poor powers of migration and to ecological barriers. Even tropical earthworms cannot withstand high temperatures and their bodies must constantly be kept cool by evaporation. As a consequence of the need for water, they cannot live in arid climates unless the soil is irrigated, and endemic (na-

tive) species are rarely found in regions that receive less than 15 in. per annum rainfall. During the dry season many species pass into a state of dormancy, coiled up within a protective coating of slime that solidifies the walls of the chamber into an earthy capsule. In this condition worms may become so dry as to be brittle and yet resume normal activity when moistened (N. A. Dmo), laboratory experiments indicate that recovery is possible after 73% of the body water has been lost. In Turkestan the activities of earthworms may be limited to 50 or 60 days of spring rainfall. Earthworms are generally most abundant in soils of approximate neutrality, but this is partly the result of improved nutritive conditions and only indirectly an effect of soil pH. Acid soils are tolerated by some species, the brandling and the gilt tail (*Den drobarna subrubicunda*) are found especially in decomposing manure. Saline habitats are favoured by a few species, such as *Pontodrilus bermudensis* which throws up sandy castings on tropical and subtropical beaches.

Important changes in the earthworm fauna result from cultivation of the land. In the steppes of central Asia, ploughing leads to a total extinction of the earthworm population, but, following irrigation, a new fauna is introduced that becomes more abundant than before. Only a relatively small number of species can withstand the special conditions of cultivation and these peregrines have been transported by man to all parts of the world. Temperate peregrines include a number of European Lumbricidae, while species of the oriental genus *Pheretima* are found in hothouses even where the winter climate is too cold for them to live out of doos. Oceanic islands are populated entirely by peregrine species.

Many earthworms are limicolous, the square tail (*Eisenella tetraedra*) occurs in river banks, sewage treatment plants, etc., some have gills and are entirely aquatic (*Alma miltota*). Even terrestrial species can live for many months in running water and die only from lack of food. *Eisenia foetida* can survive for two weeks, and *Pheretima* up to 45 hr., in an atmosphere of pure nitrogen (T. Nagano), but earthworms are readily anaesthetized by carbonic acid, and death in stagnant water must be attributed as much to this as to lack of oxygen. The appearance of large numbers of worms at the surface after heavy rains is interpreted as an effort to escape unfavourable conditions in the waterlogged soil. Earthworms are also brought to the surface by poisonous chemicals, by vibration of the ground and, it is said, by electrical devices. Some terrestrial species live among decaying leaves, etc., while others are found only in the surface layers of the soil.

FROM W. MICHAELSEN IN HANDBUCH DER ZOOLOGIE

ACTIVITIES OF EARTHWORMS IN THE SOIL

Originally the surface was covered by a mosaic tile-pavement, overlying a sandy layer above the rich humus. Earthworms swallow soil to make their burrows and also as food and this is subsequently thrown up on the surface as castings. Repetition of this process has led to a sinking down of the pavement which has become covered with earth, except on the right where stone rubble prevented the activities of the worms.

earthworm (*Microchaetus* sp.) working in shallow soil that rests on an impenetrable substratum. Many species, like the lawn-worm or night crawler, are nocturnal and come to the surface in moist humid weather to drag dead leaves and other organic matter into their burrows, the leaves are usually taken by their tips so that the stems remain protruding. Occasionally they may take fresh grass blades but there is little evidence that worms are harmful to living plants. J. K. Tarnan estimated that 10 kg. per sq. m. (over

The lawn worm (*Lumbricus terrestris*) has been taken 8 ft. below the surface but this is far exceeded by the burrows of *Den drobarna mariphiensis* in south Russia, which are said to descend to a depth of more than 26 ft. The Kommatie Flats of South Africa, cup-like depressions several feet in diameter, are attributed to the activities of a giant

20 lb per sq yd) of plant material may be dragged under ground during six months of activity per annum. Worms are generally very numerous under grass or in the soils of mixed and deciduous forests. K. Bretschger recorded 2,000 per sq m from an alpine meadow, but this is exceptionally high. Estimates vary from small numbers up to about 500 per sq m, over 2,000,000 per acre, as in the irrigated soils of Iashkent, depending on the conditions.

Gilbert White noted the importance of worms as cultivators of the soil, but it was Charles Darwin who brought the subject to the attention of the world. Darwin observed how rocks and ancient ruins have become gradually buried under a layer of fine earth thrown up by earthworms. Estimates of the amount of soil that is thus transported are of the order of 15 to 40 tonnes per hectare (6.7 to 18 tons per acre) per annum with occasional maxima as high as 81.25 tonnes per hectare recorded by A. Stockli from a golf links. Such figures do not represent the total activity of the worms, part of the castings are discharged under ground and some species never come to the surface to defecate. In Rangoon an average of 1.8 tons per acre is attributed by G. E. Gates to the activities of only two of the eight species recorded from the experimental plots. Darwin estimated that a layer of soil 1 in to 1 1/2 in thick would be formed during a period of ten years and even higher values were deduced from the depths to which sunken objects had become buried. Stockli's figures range up to 6.6 cm (2.6 in) with an average of about 1.2 cm. New soil formed in this way is not the same as the parent soil from which it was derived, although, in the case of species that live near the surface and constantly work over the same material, the difference may not be very great. The most effective soil producers are those which burrow deeply, bringing up the lower layers and dragging surface material under ground, in laboratory experiments on alpine species, H. Franz discovered that *Oecolus studiosus* is much more effective than other species which he investigated, including *Allobophora caliginosa* Soil that passes through the body of an earthworm is mechanically sorted, since larger particles are rejected. The burrows of worms also improve the aeration of the soil, permit drainage of surface water, prevent water-logging, and facilitate the down growth of plant roots. Aeration affects the bacterial flora, the presence of earthworms increases the nitrifying powers and decreases putrefaction of the soil. In addition to the physical and mechanical effects of mixing, grading and aeration, the soil is benefited in other ways. Organic matter is broken down by the digestive juices and the environment is enriched by excretory products. Castings tend to be more neutral than the parent soil, irrespective of whether this be acid or alkaline. They have a lower clay content, are richer in nitrates, organic matter, total and exchangeable calcium, exchangeable potassium and magnesium, available phosphorus, base capacity, base saturation and moisture equivalent (H. J. Lunt and H. G. M. Jacobson). However, there is probably little to be gained by addition of earthworms to cultivated lands since, in the majority of cases, peregrine species are already present in an established equilibrium. A temporary improvement in crop yield has been attributed to the fertilizing effect of the dead bodies of worms that were unable to survive in the new environment. On the other hand, measures that lead to improvement of the soil for plant growth also favour an increase in the earthworm population, with consequent beneficial action.

Earthworms are eaten by primitive people in various parts of the world and were considered a delicacy by the Maoris. They have also been used extensively in primitive medicine, apparently sometimes with good reason, modern investigations substantiate the fever-reducing and antispasmodic properties of certain oriental species. The bodies of earthworms are rich in pro vitamin D.

EARWIG, an insect of the order Dermaptera, characterized by peculiar wings and a pair of horny forceps terminating the abdomen. The large, membranous, radially veined hind wings fold both radially and transversely so as to be hidden under the short leathery tegmina. Winged species rarely fly, and many are wingless. The male forceps are larger and differently shaped than those of females, in some species they are quite bizarre. The male forceps also usually fall into two sharply marked size classes, with few of intermediate length. *Forficula* affords a classic example of such bimodality, which, however, is more complex than was supposed (Chopard 1938), the cause may be a variable relation between time of last moult and beginning of rapid forceps growth (Huxley 1932). The name earwig comes from the Anglo-Saxon *earwica* (ear creature), and most European languages have an equivalent popular name because of an ancient, widespread but unfounded superstition that earwigs crawl into the ears of sleeping persons. Several families and more than 500 species are known, mostly from the tropics, Europe has about 30 species, Great Britain 7, and North America 15. A fossil earwig (*Protodiplatys*) from Jurassic beds in Kazakhstan seems to link Dermaptera with ancestral cockroaches (Protoblattodea). The peculiar insects of the genus *Hemimeris* (family Hemimeridae), parasitic on giant African rats (*Cricetomys*), are sometimes ranked as a suborder of Dermaptera, sometimes as an order (*Hemimeria*). The Dermaptera were formerly placed in the Orthoptera (q.v.).

The common European earwig (*Forficula auricularia*) is a well known pest of gardens and houses. Commerce borne from its native Europe, it has outposts in North and South America, New Zealand and Tasmania, and seems destined to become cosmopolitan. It is omnivorous, feeding mainly on green plants, but it prefers anything more nourishing that it can find, and often swarms in kitchens. It is probably predatory, for *Labidura riparia* and other earwigs use the forceps to catch insects and hold them for eating. When alarmed or aggressive, earwigs carry the forceps over the head in scorpion fashion, the males fight sexual battles with them. *F. auricularia* overwinters in small cavities in soil, 40-60 eggs are laid therein in fall or early spring, and the mother guards and cares for the eggs and young. Nymphs hatch in April-May (Great Britain, Oregon) and remain in the nest, fed by the mother, until after the first moult. When the female opens the nest the young wander off. Four to six moults occur, after each the nymph is inflated with swallowed air and therefore is white, but it soon darkens. After the young depart the female feeds for a time and then rears a second brood. The best control is by scattering bran bait poisoned with sodium fluoride over the ground and in places where earwigs congregate, it is best done in the evening. If the bait is applied when most of the first brood of young earwigs have begun to feed at night, this brood and the adults can be poisoned before the second lot of eggs is laid. Trapping earwigs in plant pots stuffed with straw and inverted on upright sticks is a long established practice in Europe, but not a very effective one.

See I. Chopard, *Biologie des Orthoptères* (1938), J. Huxley, *Problems of Relative Growth* (1934), and works on Orthoptera (q.v.) (T. H. H.).

EASEMENT, in law, signifies a right of accommodation, or limited right of use over land belonging to another. It is distinguished from *profit à prendre* since an easement confers merely a convenience to be exercised over the land of another without any participation in the profits of it. Thus a right of way is an

an easement a right of common is a profit. An easement is distinguishable also from a licence, which, unless it is coupled with a grant, is personal to both grantor and grantee and is neither binding on the licensor, nor, in general, assignable by the licensee, while both the benefit and the burden are annexed to land.

The essential features of an easement, in the strict sense of the term, are therefore these: (i) It is an incorporeal right, a right to the use and enjoyment of land—not to the land itself, (ii) it is imposed upon corporeal property, (iii) it is a right without profit, (iv) it requires for its constitution two distinct tenements—the "dominant tenement" which enjoys the right, and the "servient tenement" which submits to it. This last characteristic excludes from the category of easements the so-called "easements in gross" (if such can subsist by English law), such as a right of way conferred by grant independently of the possession of any tenement by the grantee. The true easement is a right "appendant" or "appurtenant" to the dominant tenement.

Further classifications of easements must be noted. They are divided into (a) *affirmative* or *positive*, those which authorize the commission of an act by the dominant owner, e.g., rights of way, and *negative*, when the easement restricts the rights of the servient owner over his own property, e.g., prevents him from building on land so as to obstruct ancient lights (q.v.), (b) *continuous*, of which the enjoyment may be continual without the interference of man, e.g., access to light, and *discontinuous*, where there must be a fresh act on each occasion of the exercise of the right, e.g., a right of way, (c) *apparent*, where there are visible external signs of the exercise of the right, e.g., a right to dam up a watercourse, and *non apparent*, where such signs are absent, e.g., a right to support of one house by another.

Acquisition of Easements—Easements may be acquired (a) by express grant, (b) by an implied grant, (c) by express or implied reservation, e.g., by the owner of land in selling the fee, (d) by prescription, either at common law or under the Prescription Act, 1832. An express grant, or express reservation (*inter vivos*), of an easement cannot be affected except by deed. An easement by implied grant usually arises under the principle that a grantor cannot derogate from his own grant. Thus a man builds two houses on a close with windows deriving light from the grounds of each other. If he sells one a grant of the light derived by it over the other's ground is implied.

Easements are acquired by prescription at common law by proof of "immemorial user" by the dominant owner and those through whom he claims. A "lost grant" is presumed on proof that an easement has been enjoyed uninterruptedly for 20 years before action brought, unless the contrary is shown. To avoid the difficulties of proof of prescriptive right at common law, the Prescription Act, 1832, established more definite periods of use. In the case of easements other than light, the periods of prescription are 20 years to establish a *prima facie*, and 40 years to establish an indefeasible title. (As to light, see ANCIENT LIGHTS.) The enjoyment of the easement by the dominant tenement must be open, i.e., not hidden, and of right, i.e., not by arrangement with the owner of the tenement affected by it (*Kilgour v. Gaddes*, 1904, 1 K.B. 457).

Easements may be extinguished (i) by express release—here an instrument under seal is necessary, (ii) by "merger," i.e., where both tenements become the property of the same owner, (iii) by abandonment through non-user. In the case of discontinuous easements, the shortest period of non-user may suffice if there is direct evidence of an intention to abandon.

A word may be added here as to the right to air. The owner of a dwelling-house may acquire a right to the passage of air through it by a defined channel. If it is claimed by prescription the proof required to establish it is the old common law proof, since the air easement is not one within the Prescription Act. It may also be acquired by grant, express or implied.

In Scots law the term "easement" is unknown. Both the name "servitude" and the main species of servitudes existing in Roman law (*q.v.*) have been adopted. The modes of their creation and extinction are similar to those of English law. The statutory period of prescription is 40 years (*Scots Acts*, 1617, c. 12), or 20

years in the case of enjoyment under any *ex facie* valid irredemable title duly recorded in the appropriate register of sasines (Conveyancing [Scotland] Act, 1874). There are certain servitudes special to Scots law, e.g., "thirlage," by which lands are "thirled" or bound to a particular mill, and the possessors obliged to grind their grain there, for payment of grinding. Statutory provision has been made for the commutation of these duties (Thirlage Act, 1799), and they have now almost disappeared.

The French civil code and those of Belgium, Holland, Italy and Spain closely follow Roman law. French law is in force in Mauritius, and has been followed in Quebec (Civil Code, arts. 499 *et seq.*) and St. Lucia (Civil Code, arts. 449 *et seq.*). In India the law is regulated, on English lines, by the Easements Act, 1882 (Act v. of 1882). The term "easements" however, in India, includes *profits à prendre*. In the South African colonies the law of easements is based on the Roman Dutch law. In most of the other colonies the law of easements is similar to English law. In some, however, it has been provided by statute that rights to the access and use of light or water cannot be acquired by prescription, but municipal by-laws must be examined in this relation.

In the United States the law of easements is founded upon, and substantially identical with, English law. The English doctrine however, as to acquisition of light and air by prescription is not accepted in most of the States.

Burge, *Commentaries on Colonial and Foreign Laws*, vol. iv, pt. 2 (new ed., 4 vols., 1907-27), Jacques Vollenweider, *Étude sur les droits distincts et permanents en droit civil suisse*, Lausanne (1923).

EAST, ALFRED (1849-1913), British painter and etcher, was born at Kettering, Northamptonshire, on Dec. 15, 1849. He studied at the Glasgow School of Art and then in Paris at the École des Beaux Arts, and under Robert Fleury and Bouguereau. He began to exhibit at the Royal Academy in 1883, and became R.A. in 1913 a few months before his death. In 1906 he became president of the Royal Society of British Artists. Many of his works are to be found in the English provincial galleries, his "Passing Storm" is at the Luxembourg, Paris, "The Nene Valley" at the Venice gallery, and "A Haunt of Ancient Peace" at the National gallery in Budapest. East visited Japan in 1889, and among his best works are the landscapes he painted there. From 1902 onwards he took a keen interest in etching, and produced a large number of plates. He also published a useful, practical book on landscape painting, *The Art of Landscape Painting in Oil Colour* (1906). Shortly before his death he presented a collection of his pictures to his native town, Kettering. He died in London on Sept. 28, 1913.

EAST AFRICA, OPERATIONS IN. When the World War broke out in 1914 the garrison of British East Africa, the territory immediately north of German East Africa, was scattered and engaged on punitive expeditions remote from the enemy frontier. In the case of each Protectorate the troops were native with European officers. The German forces, some 5,000 strong, including 260 Europeans, lay ready to the hand of their commander, Von Lettow Vorbeck, a capable and determined soldier well able to employ them to full advantage. If it is remembered how keenly sensitive the native soldier is to any shortcoming in his superior and that Von Lettow had only been with his command for six months when hostilities began and kept that command efficient and formidable through four years of steadily declining fortune, some idea may be formed of the resolute nature and soldierly qualities of the German commander-in-chief. His operations consistently bore the clear imprint of his skill and personality, and there were advantages, other than his professional capacity and steady courage, upon which he could rely.

I. EARLY OPERATIONS

The country—nearly double the size of Germany in 1914—was the scene of operations, is for the most part covered by bush, dense as a rule, but occasionally thinning out to something like park land. High mountain ranges, thick with vegeta-

tion, rear themselves from bush and jungle which are fever stricken and liable to wholesale inundation during the rainy season. Rivers abound and malaria and dysentery of a malignant type, with other tropical diseases, combined to swell the casualty list of a European or Anglo-Indian force. Practically every animal imported into East Africa for the use of the British forces succumbed to the tsetse fly. The route of every British advance was marked by casualties due to diseases from which the rank and file of the enemy—askaris recruited from local tribes—were immune. Surprise by the attacker was as difficult as it was simple by the defender, who waited concealed and warned by the laborious approach of his adversary cutting roads and bridging rivers.

Supply and transport presented appalling difficulties to an advance through hundreds of miles of naturally impenetrable bush, while the defending force slowly fell back upon the magazines posted in its rear. Only an overwhelming preponderance in numbers made any advance possible, but a force starting with a strength adequate for an offensive enterprise constantly found itself reduced at best to an equality of strength on contact with the enemy. Many good cards were thus in the hand of the German commander, and he rarely failed to play them with full effect.

Naval Operations and German Advance.—On Aug. 8, 1914, two British cruisers, "Astraea" and "Pegasus," arrived opposite Dar es Salaam from Zanzibar, and, being unable to leave a garrison, the naval commander covenanted with the German governor that the latter should forbear from any hostile action in Dar es Salaam itself. Parallel to the southern frontier of British East Africa and about 50m distant from it ran the Uganda railway from Mombasa to Lake Victoria. This tempting and exposed objective, for the protection of which the British troops at the outset were hopelessly inadequate, at once appealed to Von Lettow, who on Aug. 15 seized Taveta, which lay in British territory at the eastern end of the gap between the southern slopes of Mt. Kilimanjaro and the northern end of the Pare mountains in the German Pro-

tectorate, and retired to the frontier on Oct. 8. The crew of the "Königsberg," which was blown up in July 1915, after being set on fire by the monitors "Severn" and "Maisey," joined the enemy land forces, with an armament of ten 4.7 guns. German raids along the coast, on the Uganda railway, and into the frontier districts of Uganda, Belgian Congo, Rhodesia and Nyasaland were frequent in the opening months of the campaign. These small enterprises were much simplified by the central position of the enemy and the excellent lateral communication afforded by the central railway from Dar es Salaam to Kilgoma on Lake Tanganyika. This lake was under German control until Dec. 1915, when by the operations of motor boats specially brought from Capetown the enemy was deprived of the one lake which had not been in British hands since the earliest days of the campaign.

Reinforcements from India.—It soon became apparent that, unaided, the British Protectorate forces could not hold their own, and the Government of India consented to send an expedition. On Aug. 25 its leading unit reached Mombasa with Brig-Gen Stewart, who assumed command. The rest of the expeditionary force was directed on Tanga, the northernmost German port, at the southern extremity of the Usambara mountains, healthy highlands where the bulk of the German settlers resided. Coincident with an attack on Tanga an advance against Moshi by the north of Kilimanjaro was to be made by Stewart. The expeditionary force under Brig-Gen A. E. Aitken was about 7,000 strong and (except the 2nd Loyal North Lancs) composed of Indian troops.

Failure of British Offensive.—The transports reached Tanga on Nov. 2, when the local commissioner represented the place as an open and undefended port and bombardment was deferred. Meanwhile, Von Lettow, advised of the plan by captured Indian mails, was hurrying reinforcements to the coast. When one and a half British battalions landed two miles east of the town on the evening of the arrival, they met with strong opposition and fell back. Von Lettow arrived on the evening of the following day, when British reinforcements had been landed and fighting resumed, and on Nov. 4 heavily defeated his opponent, whose casualties were 705. On the same day Stewart, checked at Longido, was compelled to retire. The British force at Tanga embarked and reached Mombasa on Nov. 5. The first British offensive had thus failed completely. Von Lettow's success at Tanga put an end for the time being to any general offensive against him, and it was not until 1916 that the next British advance was set in train.

The intervening period was occupied in raiding by both forces, with occasional engagements of a more ambitious nature. A British force was compelled to surrender on Jan. 17, 1915, at Jasini, in enemy territory, to a superior force, after 48 hours' fighting, which exhausted their ammunition and water. German losses, especially in officers, were serious, as was the shrinkage of ammunition. Maj-Gen M. I. Tighe assumed chief British command in April 1915 and in June, Bukoba, on Lake Victoria, was taken.

Reinforcements Arrive.—Aid was now sought from a different quarter, for, with the conquest of German South-west Africa by General Louis Botha in July 1915, the resources of the Union of South Africa became disposable to an extent which was impossible till the disappearance of the enemy from her own border. During the latter half of 1915 there was continuous preparation in South Africa of troops, depôts, supplies, medical stores, transport, animals and material of all kinds for use in East Africa. By Feb. 1916 one mounted brigade, two infantry brigades and one field artillery brigade, complete with all their auxiliary units, had arrived from South Africa to join Tighe. A second mounted brigade followed, together with a battalion of the Cape Corps (coloured men from the Cape Province). Tighe also had the following European units: the Calcutta Volunteer Battery, the 2nd Loyal North Lancs, 25th Royal Fusiliers, 2nd Rhodesians and two local settlers' corps. India sent him from her native army ten infantry regiments, one squadron of cavalry and two mountain batteries. The battalions of King's African Rifles were the original native Protectorate force. At the same time, Von Lettow's force had reached the highest limit which it attained in the campaign and was probably over 20,000. The exact combatant strength

tectorate. An enemy force here was a standing menace to the British capital at Nairobi, and constantly raided the railway line.

In September the enemy cruiser "Königsberg" returned to Dar es Salaam and on Sept. 20 surprised and destroyed the "Pegasus" while undergoing repair in the Zanzibar roadstead. A combined enemy operation against Mombasa, for the execution of which the "Königsberg" was to attack the port in conjunction with a land force moving north along the coast, failed, as the "Königsberg" was driven by the ships of the Cape Squadron into the Rufiji delta, where she was run aground. The land force began its march along the coast on Sept. 20, was repulsed at Gazi, 25m from

is difficult to estimate, for there were many carriers of whom a percentage were armed and many trained as askaris. The askari in his own country is a soldier of high value. Such a force, with a strong leaven of Europeans, under a skilful and determined commander, was a formidable adversary in tropical bush country.

German Ammunition Supplies.—In April 1915 the mind of Von Lettow, which had been sorely exercised by his shortage of ammunition, was relieved in the following remarkable manner. A British ship, the "Rubens," seized at Hamburg, left that port loaded with arms and ammunition and appeared off Tanga on April 4, being sighted by H.M.S. "Hyacinth." Fearing Manza Bay on fire and abandoned, she was boarded by bluejackets, who found her timbered up and bristled down. After firing more rounds the "Hyacinth" steamed away on the assumption that her quarry would burn herself out. The Germans returned and salvaged almost the entire cargo, and a largely increased volume of enemy fire from the Mauser pattern 1898 rifles which the "Rubens" had brought was the result. This operation was repeated a year later.

II OPERATIONS UNDER GENERAL SMUTS

The chief command in East Africa was assumed by General Smuts in Feb. 1916. He had previously declined the post, but when General Smith Dorrien was compelled to relinquish the command in consequence of illness he accepted it. He reached Mombasa on Feb. 19 and found the railway completed from Voi to Serengeti, 500 miles from Salata Hill. The German advanced position from Taveta. A week earlier an attack on Salata had failed. The rainy season was at hand and movement would then become impossible. Smuts telegraphed to Lord Kitchener that he was ready to carry out the occupation of the Kilimanjaro area at once. The proposal was agreed to and Smuts proceeded to advance.

British Advance on Taveta.—An attack, designed primarily to hold the enemy, was to be delivered on Salata by a force under General Malleson, while Stewart was to repeat his attempt of 1914 to reach Moshi by the north of Kilimanjaro and thence to intercept any enemy retirement in his direction. General Van Deventer with a mounted brigade, moving by Malleson's right, was to cross the Lumi river, and by way of the foothills of Kilimanjaro cut the enemy line of retreat between Taveta and Moshi. The execution of this movement unobserved was the only chance of surprising the enemy, for it was apparent to Von Lettow, who had made all preparations for retirement, that Taveta was Smuts' objective. This surprise was effected. Van Deventer moved on March 8 and on the following day his troops were astride the Moshi-Taveta road. On the same day the Germans evacuated Salata and took up new positions on two hills, Latema and Reata, covering the gap between the Pare mountains and Kilimanjaro. The main enemy force was posted at Himo, 500 miles from the gap, whence it could move in any direction to attack or retire. The progress of Stewart's force was so slow that his movement was without effect.

The new enemy position was attacked on March 11 and, after severe fighting all day and the succeeding night, was occupied on the morning of the 12th by a general advance in support of the elements which had won their way to the two peaks during the night and caused the retirement by the enemy.

German Withdrawal.—Von Lettow now withdrew his entire force to a position (Kah-Ruvu) which situated south of the Taveta-Moshi road from Kah railway station and toward along the northern end of the Pare mountains. He was followed up and attacked on March 18 from Latema Nick by Brig. Gen. Sheppard, and on March 20 Van Deventer went from Moshi to turn the enemy at Kah. He seized Kah on March 21 and on the following night, after a very severe action with Sheppard, the enemy withdrew to Lembeni, 200 miles S. of Kah. Von Lettow abandoned one 4.1 gun, and had expended ammunition to an extent which he could ill afford, but his force was intact and the timely arrival of the second blockade runner at this juncture, with four 4.1 field howitzers, gun and small arm ammunition, machine guns, stores, provisions and clothing was an inestimable stroke of good fortune. Here the operations which had been undertaken before the rainy season were concluded and the British forces took up positions covering Taveta and Moshi and facing the enemy at

Lembeni.

During the ensuing rains Smuts reorganized his force and prepared to resume the offensive at the earliest possible date. He could rely for assistance in his main operations upon the Belgians in the north-west and the British force under Maj. Gen. Northey, operating from Ny island, to the south-west. For reasons fully recorded in his dispatches, Smuts decided at once to send Van Deventer with a mounted force rapidly by Arusha to Kondoa Irangi and thence to the central railway and east along that line to Morogoro. His own force was to move south by the Pangani, and make for the same ultimate objective, Morogoro. It was hoped that Von Lettow would there be brought to bay by the two converging forces.

New British Offensive.—Van Deventer moved on April 3 and occupied Kondoa Irangi on April 19, capturing the enemy garrison at Lol Kisale en route. He reached Kondoa Irangi after heavy casualties in men and animals from disease and was there cut off and reduced to immobility as a consequence of his losses and the advent of the rainy season. Von Lettow concentrated a force against Van Deventer and fighting ensued, but the German attacks, with one exception, lacked vigour and were all repulsed. Van Deventer's position was eased by the end of May, when Smuts began his advance down the Pangani and the Belgians moved on Tabora. Maj. Kraut was in command of the German force opposite Smuts when the latter set his troops in motion southwards from Moshi on May 18, Von Lettow having assumed direction of his concentration against Van Deventer.

Systematically outflanked by his opponent, whose main advance along the Pangani was supplemented by flank movements by the Pare and Usambara ranges, Kraut found himself compelled to leave the Tanga railway and retire upon Handeni. This place was seized by Smuts on June 19, Korogwe having been occupied four days earlier. On June 24 the Germans were attacked simultaneously on three sides, but, after determined fighting, withdrew into the Nguru hills. Smuts was now compelled to halt his force on the Mshu river. In a month 2500 had been covered, but malaria had reduced the strength of all units, combatant and non-combatant, in some instances to 30% of their original numbers. The troops were on half rations, and the transport, which included a variety of types of motor vehicles, was much damaged. The coast region was now dealt with, and with the aid of the navy, Tanga, Pangani, Sadani and Bagamoyo were successively occupied between July 17 and Aug. 15. The removal of the British base to Tanga saved 2000 miles of rail transport. Dar es Salaam was occupied on Sept. 4, but three months elapsed from its capture before it could be used as the base.

German Retreat.—Von Lettow now moved the bulk of his force once more opposite Smuts, and on June 24 Van Deventer resumed his advance and at the end of July held the central railway from Kilimatinde to Kilombo, about 100 miles. On Aug. 9 he was ready to move on Morogoro. The Belgians were at the same time advancing on Tabora against the German force under Maj. Gen. Wahle, who was left to do his best unaided, though some reinforcements were sent south-west against Northey. Smuts moved again on Aug. 5, opposed by a detachment of the enemy whose main force was withdrawn to Kilosa, whence it proceeded south towards Mahenge, the eventual direction of the enemy retirement on all fronts. Von Lettow directed the remainder of his forces by a route through the Uluguru mountains, thus foiling the attempt to intercept him at Morogoro. Heavy fighting ensued in these mountains but Kisumu fell into British hands on Sept. 15 and Von Lettow retired to Mgeta river and there entrenched himself. On this front, during the last three months of 1916, activity was confined to such minor affairs as are usual between opposite entrenched forces. Civil administration was instituted in the occupied area behind the British forces.

Belgian Operations.—The Belgian force (also native), under Maj. Gen. Tombour with European officers, was divided into two brigades, the Northern (Col. Molitor) and the Southern (Lt. Col. Olsen) and operated in the north-west of German territory, opposed by Wahle, who was instructed to avoid a decisive action. The Belgian operations, well planned and successfully executed,

were of prime importance to the general campaign. Broadly described, they were as follows. Molitor invaded Ruanda by the north of Lake Kivu while Olsen co-operated south of him by the north of Tanganyika. The movements started on April 4, and by the end of May the Belgians were in possession of Ruanda. Molitor then sent columns south-west to join hands with Olsen and other columns south-west to Lake Victoria, which was reached on June 27.

In the middle of July, on a front between Tanganyika and Victoria, Molitor and Olsen moved south on the respective objectives of Tabora and Kigoma, the terminus of the central railway on Tanganyika. Olsen occupied Kigoma on July 28 and Ujiji on Aug. 2, and then moved east on Tabora. Co-operating with Molitor was a British column under Brig. Gen. Sir C. P. Crewe, who captured Mwanza on the southern shore of Lake Victoria on July 14. On Sept. 19 Molitor occupied Tabora which Wahle had evacuated the previous day, leaving behind his sick with civilians and prisoners of war. Crewe reached the central railway a week later.

British Advance from Rhodesia.—By this time Northey had succeeded in interposing some of his forces, which were in three columns under Lt.-Cols. Hawthorn, Murray and Rodgers (the last a South African unit), between Tabora and Mahenge. His advance was on an original front between Lakes Nyasa and Tanganyika. Murray occupied Kasanga (Bismarckburg) at the south end of Tanganyika on June 8. The Germans were defeated at Malangali on July 24, and on Aug. 29 Iringa was occupied, Lupembe having been seized ten days earlier. Northey, ordered with van Deventer, now at Kilosa, to deal with the enemy in the Mahenge district, was much outnumbered by forces already in touch with him and Wahle's columns approaching from the north, and on the night of Oct. 21 most of Wahle's troops broke through him. On the same day Kraut was heavily defeated at Mkipira. Hawthorn secured the surrender of an enemy column at Ilembe. On Dec. 24 van Deventer and Northey attacked the Mahenge force. An enemy column surrendered to Northey, but the force engaged with van Deventer escaped him after fighting from Dec. 25 to 28.

Position at End of 1916.—By the beginning of 1917 Smuts had evacuated 12,000 to 15,000 white troops (South Africans), mostly victims to malaria, and they had been replaced by the Nigerian Brigade (Brig.-Gen. Cunliffe) and fresh battalions of the King's African Rifles. Kilwa and Lindi, south of Dar es Salaam, had been seized by the navy and a force under Maj. Gen. Hoskins had been concentrated at Kilwa. On Jan. 1, 1917, an advance was made on the Mgeta position, but after heavy fighting the enemy retired across the Rufiji at Kibambawe. Smuts now went to England and Hoskins assumed the chief command. The rains ensued, and to clear the north bank of the Rufiji was all that could be barely accomplished before operations ceased. Perforce Hoskins completely reorganized his command, but before operations were resumed he was ordered to Palestine. His successor was van Deventer, who assumed command at the end of May 1917.

III. VAN DEVENTER'S OPERATIONS

The enemy forces were disposed as follows. Von Lettow near Kilwa, Wahle in the Lindi area, Tafel at Mahenge, detachments between Kilwa and Lindi, and near the Ruvuma. Northey lay south and west of Tafel with another British force at Iringa, north-west of the enemy. The rest of van Deventer's troops were to act against Von Lettow. In pursuance of this decision an advance was made by the Kilwa force under Brig.-Gen. Beves on July 5 towards Lwalale. The enemy fell back to Narungombe, where a severe engagement took place on July 19. The enemy retired south, but the Kilwa force was unable to move again until mid-September. In August the enemy was driven from the Lukuledi estuary to allow of an advance inland from Lindi. The Kilwa force (Hannington) was to move south and that at Lindi (Beves) west. These operations were marked by the hardest fighting of the whole campaign. Von Lettow fell back, under pressure by Hannington, towards Nyanga, 40m S.W. of Lindi, Wahle retiring before Beves. On Oct. 15 a four days' battle began between Beves' force and the enemy under Von Lettow

joined by Wahle. The latter retained their position and it was ten days before Beves' force under the command of Cunliffe could resume the offensive.

On Oct. 8 Tafel, pressed by Northey with Belgian co-operation from the north, had retired from Mahenge, and, breaking through two weak detachments on Nov. 16, moved south-east towards Von Lettow, whom he was debarricaded from joining by the Kilwa force. Vainly endeavouring to join the main body, Tafel reached the Ruvuma, but, unable to procure food, surrendered with his entire force on Nov. 28.

Germans Retire to Portuguese Territory.—On the night of Nov. 25–26 Von Lettow, having shed all weaklings, crossed the Ruvuma into Portuguese territory and thenceforward moved as the circumstances of his position, without bases and short of ammunition, dictated. Early successes in the new sphere of action, especially at Ngomano, gave the Germans food, ammunition, arms and clothing, and when the rainy season set in, in Jan. 1918, they were able to rest for a short time.

The operations during 1918 were carried out almost entirely by natives, the King's African Rifles, and Von Lettow fell back upon guerilla tactics. Against him in Portuguese territory were sent columns from the east and south shores of Nyasa, and another (Brig. Gen. Edwards) advanced west from Porto Amelia midway between the Ruvuma and Mozambique. After various engagements Von Lettow marched in May south to the Lurio river, 200m from German territory, captured Ille, and in June reached the coastal region near Quelimane. On July 1 he captured Nyamakura, 25m from Quelimane, and in the middle of August at Chalanal, eluded envelopment by converging columns. Turning north-west, he was engaged by Hawthorn (who had succeeded Northey) at Lioma, east of Lake Shirwa. After several encounters, the German force reached the Ruvuma again on Sept. 28 and, after resting at Ukena, where Wahle was left, set out for Rhodesia. On Nov. 1 Von Lettow made an unsuccessful attack on Fife and, turning south-west, took Kasama on Nov. 9. Advised on Nov. 13 of the Armistice, he accepted it the following day, and on Nov. 23 formally surrendered to General Edwards at Abercorn. With him were Dr. Schnee, the governor, and Maj. Kraut, together with a force of 30 officers and 125 other Europeans, 1,165 askaris and 2,891 other natives (including 819 women), 1 small field gun, 24 machine-guns and 14 Lewis guns.

Troops Engaged, Casualties, Etc.—The troops employed by the Allies in East Africa included 52,339 sent from India (5,403 British) and 43,477 South African whites. East African and Nyasaland settlers, Rhodesian volunteers and the 25th Fusiliers numbered about 3,000, African troops (King's African Rifles, Nigerians, Gold Coast Regiment, Gambia Company, Cape Corps) and West Indians about 15,000, an approximate total of 114,000 not reckoning Belgian native troops (about 12,000 in all), Portuguese and the naval force engaged. The greatest number in the field at any one time, May to Sept. 1916, was about 55,000, the lowest, in 1918, 10,000, all African, save administrative services. See also KENYA.

British and Indian casualties were returned at 17,823, of these 2,762 were in the South African Forces. These figures are exclusive of casualties among carriers and of deaths and invaliding through sickness, which among the South Africans alone exceeded 12,000. The cost of the campaign to Great Britain, inclusive of Indian and South African expenditure and that of the local protectorates to March 1919, was officially estimated at £72,000,000.

EAST ANGLIA, one of the kingdoms into which Anglo-Saxon Britain was divided. Bede gives no information about its origin except that its earliest settlers were Angles. The kingdom of East Anglia comprised the two counties of Norfolk and Suffolk, with a western boundary probably formed by the fens of Cambridgeshire.

This kingdom first appears in Bede's narrative early in the 7th century, when its power was at its height. Towards the end

of the reign of Aethelbert who died about 616 Raedwald of East Angla began to win for himself the chief position among the Anglo-Saxon kings of his day. His position was assured, at least temporarily in 617, when he decided to espouse the cause of the Northumbrian prince Edwin, then a fugitive at his court, and defeated Aethelfrith of Northumbria on the banks of the Idle a tributary of the Trent in Mercian territory. Raedwald had been converted to Christianity in Kent but after his return home he relapsed. Bede states that he was the son of Tytil the son of Wuffa from whom the East Anglian royal family derived their name Wuffingas. According to the *Historia Brittonum* Guifa (Wuffa) was the son of (Guecha) Wehha who first ruled the East Angles in Britain. This would put the organization of the kingdom in the first or second quarter of the 6th century. Eorpwald the son of Raedwald, was converted to Christianity by Edwin but was soon afterward slain by Richert (627 or 628), whereupon the kingdom again became pagan for three years, when Sigebert, the brother of Eorpwald, became king and founded a see for Felix at Dunwich. Sigebert also founded a school in East Angla, and on the arrival of an Irish missionary named Fursey he built him a monastery at Cnobheresburg, perhaps to be identified with Burgh castle. Before 644, however, Sigebert resigned the crown in favour of his brother Egric and retired to a monastery. Shortly afterward both brothers were slain by Penda of Mercia in his invasion of East Angla, and Anna became king. This king was an enthusiastic Christian and converted Cenwalh, king of Wessex who had fled to his court. Two of his daughters, Saethryth and Aethelberg, took the veil, while another, Seburg, was married to Larcenbert king of Kent, a fourth, Aethelhyth, after two marriages with Fondbert of the South Gyrwe and Egrifn of Northumbria, became abbess of Ely. In 654 Anna was slain by Penda of Mercia and was succeeded by his brother Aethelhere, who was killed in 655 at the Winwæd, fighting for the Mercian king against Oswio of Northumbria. In 673 Archbishop Theodore divided the East Anglian diocese into two, Elmham being the seat of the northern Dunwich that of the southern bishop. A long blank follows in the history of this kingdom, until in 792 Offa of Mercia slew Aethelbert king of East Angla who is said to have been his son-in-law. East Angla was subject to the supremacy of the Mercian kings until 825, when its people slew Beornwulf of Mercia and with their king acknowledged Egbert of Wessex as their lord. In 870 Edmund, king of East Angla, was killed by the Danes under Ivar and Ubba, the sons of Ragnar Loekbrok.

The following is a list of the kings of East Angla of whom there is record: Wehha, Wuffa, Raedwald son of Tytil and grandson of Wuffa (reigning 617), Eorpwald, son of Raedwald (d. 627 or 628), Sigebert, brother of Eorpwald, Egric brother of Sigebert (both slain before 644), Anna, son of Ene and grandson of Tytil (d. 654), Aethelhere, brother of Anna (d. 655), Aethelwald third brother, Aldwulf (succ. 663, d. 713), son of Aethelric and grandson of Ene, Elfwald son of Aldwulf (d. 749), Hun Beonna and Albert, Aethelbert (792), Edmund (870).

After the death of Ragnar Loekbrok's sons East Angla was occupied by the Danish king Guthrum, who made a treaty with Alfred settling their respective boundaries, probably about 880. Guthrum died in 890. A later king named Eohric took up the cause of Aethelwald, the son of Aethelred I, and was slain in the fight with the Kentish army at the Holm in 905. A war broke out with King Edward the Elder in 913, in 921 a king whose name is unknown was killed at the fall of Tempsford, and in the same year the Danes of East Angla submitted to Edward the Elder. From this time, probably, East Angla was governed by English earls the most famous of whom were Aethelstan, surnamed Half King (912-926), and his sons Aethelwold (926-962) and Aethelwine surnamed *Den amicus* (962-992).

EAST BENGAL (EAST PAKISTAN), the isolated eastern province of Pakistan separated from the country's main tract in the

northwest by about 1,000 mi. of Indian territory. Although it has only about one seventh of the total area of Pakistan it contains about 58% of the total population. Area 54,501 sq. mi. Population (1951 census) 42,062,610 (including about 32,200,000 Moslems, 9,200,000 Hindus). East Bengal comprises the eastern part of the former British Indian province of Bengal, partitioned between the dominions of India and Pakistan in 1947, together with most of the former Assam district of Sylhet. The provincial capital is Dacca (q.v.). East Bengal is governed by a premier and elected legislature and is administered in three divisions (Dacca, Chittagong, Rajshahi) divided into 17 districts.

History—East Bengal's isolation from the Moslem home lands in the northwest had at least one advantage in 1947 in that the province was largely withdrawn from the kind of violent strife that accompanied the Punjab partition. In the early years of Pakistan, moreover, East Bengal alone of the provinces enjoyed reasonably tranquil relations with Karachi. Indeed on the death of Mohammed Ali Jinnah (q.v.) in Sept. 1948, the East Bengal provincial premier, Khwaja Nazimuddin, succeeded him as governor general.

After 1949, however, the province's difficulties centred around three topics: race, minorities and provincialism. Jute is almost all grown in East Bengal but is processed for export in Indian West Bengal. In 1950, consequent upon the Indian rupee's devaluation, a dispute arose over raw jute prices, India, in retaliation, stopped coal supplies to East Bengal, mills closed in Calcutta and the disastrous interstate migrations, successfully coped with in 1947-48, began again. Only by a statesmanlike agreement signed in Delhi in April 1950 was more serious communal trouble avoided.

At the same time arrangements were made to deal with difficulties arising from the numerous religious and national minorities remaining in each half of the old province. In the summer of 1953 the Indian and Pakistan prime ministers also reached agreement about the exchange of enclaves between East Bengal and Cooch Behar (West Bengal). The hope for communal peace had been emphasized in 1952 by the abolition of the representation of special interests in the East Bengal legislature.

During 1951-53 extremists in the eastern province had talked much of greater provincial autonomy, the federal government, however, anxious to bind the isolated eastern wing more closely to the centre proposed in 1953 a new federal legislature in which East Bengal would have 10 out of 50 seats in the upper house, 165 out of 300 in the lower. (See also **BENGAL**.)

EASTBOURNE, a seaside town, municipal and county borough in the Eastbourne parliamentary division of East Sussex, Eng., 63 mi. S.E. of London by road. Pop. (1951) 57,801. Area 17.7 sq. mi. Eastbourne lies partly on the coastal plain and partly on the eastern slopes of the South Downs below Beachy Head (575 ft.). Because of its position and easy access from London it became a health and holiday resort as well as a residential town with a number of boarding schools, including Eastbourne college for boys (founded 1867), and convalescent homes. The accommodation and entertainment of visitors provide the chief employment, fishing, toy-making, brewing and printing are also carried on.

The earliest settlement, East Bourne was a mile from the sea in what is now called the Old Town, there is the parish church of St. Mary, a fine Transitional-Norman building, there too can be seen the bourne or stream to which the name alludes. Subsequently two small fishing settlements grew up. South Bourne lying back from the shore and Seashouses facing the beach, but the modern development of Eastbourne dates from the early 19th century. It owes its charm as a town to the 7th duke of Devonshire, the family is one of the principal landowners, and a family seat, Compton place has been the old and new towns. Eastbourne was one of the first English experiments in town planning, with wide, tree-lined streets and ample open spaces. The Saffrons sports ground faces the town hall, the Manor house (18th century) houses the Town and Art gallery. The sea frontage extends for more than 3 mi. and is partly built in terraced promenades, the Wish tower (a Martello tower) and the Great Redoubt date from the early 19th century. The borough includes a considerable area of the neighbouring downs, about 4,000 ac. of which are preserved. The town

was incorporated in 1883 and was constituted a county borough in 1911, and the present parliamentary division was constituted in 1948.

EAST CHICAGO, a city of Lake county, Ind., U.S., on Lake Michigan, adjoining Gary, Hammond and Whiting, about 20 mi S.E. of the Chicago Ill. loop. It is served by the Baltimore and Ohio Chicago Terminal, the Chicago, South Shore and South Bend (electric), the Elgin Joliet and Eastern, the Indiana Harbor Belt, the Pennsylvania and the Wabash railways. The population was 54,263 in 1930 and 54,637 in 1940 by the federal census.

East Chicago became one of the rapidly growing cities in the Calumet region, an important manufacturing district. Indiana Harbor, the part of the city that lies along the lake, is connected with the Grand Calumet river by a ship canal. The commerce of the port ordinarily consists largely of incoming coal, iron ore and limestone and shipments of gasoline and steel products. There are immense steelworks and oil refineries and other important industries, including meat packing, railroad equipment, chemicals and cement. East Chicago was founded in 1888 and incorporated as a city in 1893. Its rapid growth began in the 20th century. Between 1900 and 1910 the population increased from 3,411 to 19,098, and, next decade almost doubled.

EAST CLEVELAND, a city of Cuyahoga county, O., U.S., on the New York Central railroad, adjoining Cleveland. It is a residential suburb. The population was 40,447 in 1950, 39,495 in 1940 and 29,667 in 1930 by federal census. It has a city-manager form of government.

EASTER, the most joyous of the Christian festivals, observed annually throughout Christendom in commemoration of the resurrection of Jesus Christ, on the first Sunday after the full moon following the vernal equinox.

Though Easter Sunday is the central point in the observance of the events connected with the death and resurrection of Christ the Easter season extends from Ash Wednesday, the first day of Lent, to Whitsunday, which commemorates the day of Pentecost. This period of the Easter cycle may be divided into four periods: (1) the preparatory fast of the 40 days of Lent, (2) the 15 days, beginning with the Sunday before and ending with the Sunday after Easter, during which the ceremonies of the Holy Week and the services of the octave of Easter are observed, (3) the octave of Easter, during which the newly baptized wear their white garments, (4) the paschal season beginning at Easter and lasting till Whitsunday.

Since the last days of Christ coincided with the Passover feast of the Jews and his death fell upon the day of the feast of the Passover, on the 14th day of the month of Nisan, it was natural that the early Christians should associate the sacrifice of the true Lamb of God and the joyful promise of his resurrection with the traditional Passover observances, adding to the older festival the new idea of Christ as the sacrificial Lamb, and should celebrate the old and the new feasts at the same time. Since the Jewish calendar consisted of 12 lunar months, or 354 days, with periodically an extra month inserted to bring it in line with the solar calendar, the date of the new Christian festival like that of the Passover, shifted from year to year in relation to the Julian calendar, then used by the Romans, which was calculated according to the solar year. Thus Easter has remained a movable date, falling anywhere between March 22 and April 25, and has determined the date of all the events falling within the Easter cycle.

Easter Customs—The close association of Easter with the Jewish Passover, or Pesach, is indicated by the fact that among non-Teutonic peoples the name for this holy day is derived from the same root as the Hebrew word *Pesach* (Latin, *Festa Paschalis*, French, *Pâques*). The English word "Easter," however, corresponding to the German *Ostern*, reveals Christianity's indebtedness to the Teutonic tribes of central Europe. Christianity, when it reached the Teutons, incorporated in its celebration of the great Christian feast day many of the heathen rites and customs which accompanied their observance of the spring festival. That the festival of the resurrection occurred in the spring, that it celebrated the triumph of life over death, made it easy for the church to identify with this occasion the most joyous festival of the

Teutons, held in honour of the death of winter the birth of a new year and the return of the sun.

Eostur monath, or Easter month corresponding to our month of April and, according to Bede (*De Temp. Rat.*, ch. xv) dedicated to Eostre, or Ostara, goddess of the spring, gave its name to the Christian holy day.

The customs and symbols associated with the observance of Easter have ancient origins, not only in the Teutonic rites of spring but also far back in antiquity. The practice of eating eggs on Easter Sunday and of giving them as gifts to friends or to children probably arose because, in the earlier days of the church, eggs were forbidden food during Lent and were therefore always eaten on Easter Sunday. But the conception of the egg as a symbol of fertility and of renewed life goes back to the ancient Egyptians and Persians who had also the custom of colouring and eating eggs during their spring festival. This ancient idea of the significance of the egg as a symbol of new life readily became the idea of the egg as a symbol of resurrection, as it came to be interpreted by the Christians. The colour red used in dyeing the eggs has been variously interpreted as signifying the sun, the blood of Christ shed on Calvary and the joy of Easter.

In many places Easter games played with eggs were traditional, and the annual egg rolling held on the lawn of the White House in Washington, D.C., is a modern reminder of these old time sports.

Like the Easter egg, the Easter hare, now an accepted part of the traditional Easter story, came to Christianity from antiquity. The hare is associated with the moon in the legends of ancient Egypt and other peoples. It belongs to the night, since it comes out only then to feed. It is born with its eyes open and, like the moon, is "the open eyed watcher of the skies." Through the fact that the Egyptian word for hare, *am*, means also "open" and "period," the hare came to be associated with the idea of periodicity, both lunar and human, and with the beginning of new life in both the young man and the young woman, and so a symbol of fertility and of the renewal of life. As such, the hare became linked with the Easter or paschal, eggs. In the United States where the hare is unfamiliar, it is the Easter rabbit which is fabled to lay the eggs in the nests prepared for it or to hide them for the children to find.

Various other customs and traditions are associated with Easter, many of them surviving into the 20th century, especially in more remote places. According to old superstition, the sun rising on Easter morning dances in the heavens, this belief has been traced to the old heathen festival of spring, when the spectators danced in honour of the sun. The exchange of the Easter kiss was a ceremonious and joyful Easter rite. The Easter greeting, "Christ is risen," and answered by "He is risen indeed," was universally familiar in Russia until the time of the Revolution of 1917.

The tradition that new fires should be started on Easter, lighted by the friction of wood or of flint and steel, goes back to old Teutonic superstition. According to the belief held in many places, it was unlucky not to wear some new article of clothing or personal adornment on Easter, the modern custom, seemingly entirely worldly of appearing in a new costume on Easter Sunday may go back to this belief, or perhaps may spring from the universal feeling that the Easter tide is the time of casting off the old and the beginning of the new. And those families who by custom eat ham on Easter Sunday are unwittingly following an old practice of the Roman Catholics of England, who ate a gammon of bacon on Easter to show their contempt for the Jews, to whom pork is forbidden.

The religious ceremonies of the Roman Catholic Church and of the Eastern Church in honour of Easter Sunday and the resurrection were always elaborate. The liturgical colour for Easter was white as the sign of joy, light and purity, and the churches and altars were adorned with the best ornaments that each church possessed. In England, however, the Puritans, who abhorred the Catholic ritual and the excesses which often accompanied the observance of the church festivals refused to celebrate Easter.

Thus at first in the U.S., with the exception of a few states such as Louisiana and Virginia, where the Puritan element was not dominant, Easter was not observed. It was not until the latter part of the 19th century, particularly during the Civil War, that

the Protestant churches other than the Lutheran and the Episcopalian began to mark this day by special services. The desire of the churches to bring consolation to those bereaved by the war made it natural for them to choose Easter Sunday with its promise of the victory of life over death as the occasion for special emphasis. The clergy preached special sermons and the churches and their altars were decorated with a profusion of flowers. For this purpose a Bernini hilly was used so widely that it became known as the Easter lily. As in the Roman Catholic Church from its early days Easter became a favourite time for baptism. The Protestant churches also followed the custom of holding sunrise services on Easter morning.

Fixing Date for Celebrating Easter—Confusion early arose as to the proper date for the observance of Easter. According to the Gospels Jesus celebrated the Passover on Thursday, whereas the priesthood observed it on Friday the day of the crucifixion. When the church appointed Easter as a holy day, a sharp controversy ensued as to whether it should be celebrated on the 14th or the 15th of the month, the disputants being respectively called the *Quartodecimans* and the *Quintodecimans*. It is uncertain, in fact, as to whether the early Easter festival commemorated the crucifixion of Christ or the resurrection or both.

Early in the history of the church a dispute arose between the Jewish and the Gentile Christians. The Jews linking the festival of the death and resurrection of Christ with the tradition of Jewish first of the Passover, maintained that Easter should be observed like Passover on the 14th of Nisan regardless of the day of the week upon which it fell. On the other hand the Christians of Gentile descent insisted that the holy day be observed on Sunday, since it was on that day of the week that the resurrection had occurred, and that the date of the crucifixion be observed on the preceding Friday. This dispute persisted into the 4th century, the western churches generally celebrating Easter on Sunday and the eastern churches following the Jewish tradition.

In A.D. 325 Constantine convened the Nicæa council, where the decision was made that Easter should be observed, as it is now, on the first Sunday after the full moon following the vernal equinox, to be fixed each year at Alexandria, then the centre of astronomical science.

Further difficulties, however, stood in the way of establishing a universal date for Easter. The time of the vernal equinox, by which the date was determined, varied according to variations in the longitude, though later it was arbitrarily set upon March 21. Furthermore, the inexactness of the Julian calendar, in addition to the difficulty of adjusting the lunar calendar upon which the date of Easter partly depended, with the solar year, led to many inaccuracies in calculation and to many divergent opinions as to what date was the correct one.

The Gregorian calendar promulgated in 1582 was not at once universally adopted, and thus arose another disagreement. The western churches accepted the new calendar more or less readily, although it was not until 1752 that it was adopted in Great Britain and Ireland. The eastern churches held to the old calendar, refusing to accept a reform which came from the Roman Catholic Church, and it was not until 1926 that Bulgaria adopted the Gregorian calendar, followed in 1918 by the Soviet Union and in 1924 by the Greek Orthodox Church. Many Eastern Orthodox groups continued to hold to the older Julian calendar and could not, therefore, celebrate Easter with the western world.

The inconvenience of an Easter festival which falls upon a different date from year to year, a date which may vary as much as 35 days, is felt not only in the church calendar but in the civic community as well. Since 1900 chambers of commerce, national and international, have repeatedly passed resolutions urging a fixed date for Easter, and in 1923 such a resolution was addressed to the Holy See. The League of Nations to which the question was referred, called a conference at which were represented the Roman Catholic, the Eastern Orthodox and the Anglican churches, where the delegates reached the conclusion that the nations concerned shared a general desire that the date of Easter should be fixed. After the conference of 1923 many proposals for calendar reform were brought forward, and in 1928 the British parliament passed

the Easter act, which, contingent upon its acceptance internationally, fixed Easter day as the first Sunday after the second Saturday in April, falling between April 9 and 15. The proposed world calendar, strongly advocated by those interested in calendar reform, assigned to each day of the year its own day of the week and to both secular and religious holidays, including those of the Easter cycle a fixed date.

EASTER ISLAND (Isla or Pascua), also known as Rapa-nui, a dependency of Chile situated in the South Pacific ocean in 27° 10' S lat and 109° 26' W long, about 2,000 mi W of Caldera, Chile and 1,100 mi E of Pitcairn, the nearest inhabited island. The first European to land on the island was the Dutch admiral Jacob Roggeveen on Easter day, 1722, whence its name. There is no evidence that the aboriginal inhabitants of this easternmost outpost of Polynesia had a name for the island. Although the population of the island prior to its discovery by Roggeveen is not known it is improbable that it ever exceeded 4,000. Death from introduced diseases, capture by slave traders, winter murder, internecine warfare, and voluntary emigration reduced the native population to 175 by 1877. Destroyed too, was the culture as well as the knowledge of the past culture of these agricultural people, whose ancestors carved remarkable stone monuments and incised ideographic script on wooden tablets. Although Easter Island was not annexed by Chile until 1888, whites have been permanently established there since 1864. Under Chilean authority the native inhabitants were confined to the village of Hanga-roa on the west coast, where they had approximately 5,000 ac of land for subsistence purposes. The remainder of the grass-covered island (30,000 ac) was owned by the *Compañía Explotadora de la Isla de Pascua* of Chile and was devoted to the grazing of sheep and cattle. In 1934 the total population of the island was 456 of whom 22 were lepers confined to a hut about 2½ mi N of Hanga-roa.

Archaeology—Archaeology is concerned almost entirely with stone remains, together with a few small objects in shell and bone. Such skulls as have been collected from graves show no traces of high antiquity. Easter Island is destitute of metal objects and pottery, although clay suitable for potting occurs in the craters. The stone remains include houses, platforms, semipyramidal cairns, circular towers, cisterns, statues, rock carvings, adzes or chisels, obsidian spearheads and fishhooks.

The most striking monuments are the burial platforms, called *ahu*, and the statues surmounting them. About 260 platforms have been counted in varying degrees of preservation, fringing the coast in almost unbroken succession, while a few are also found inland. Only about 100 of these were intended to support images.

A typical image *ahu* consists of a wall parallel with the sea, measuring up to 300 ft in length and 15 ft in height and buttressed to landward with a slope of masonry. The images stood in a single row facing inland on the central portion of the wall, which projected toward the sea and a single *ahu* might contain from 1 to 15 statues. The maximum extension of the landward slope was about 50 ft, and beyond this was a paved area. The masonry of huge polygonal or rectangular blocks is sometimes beautifully finished and fitted together but is more often of rough material. These *ahu*, which were still used within living memory, served for the exposure of dead bodies and contained vaults for the subsequent burial of the bones. There are also a number of rough, semipyramidal cairns, up to 12 ft in height, containing burial vaults, these appear to be of more recent construction than the *ahu*.

All the statues belonging to the *ahu* have now been thrown down and many broken. But by the accounts of the early voyagers the greater number of them were standing in the 18th century, and Roggeveen refers to religious ceremonies which appeared to him to indicate worship of the statues. The *ahu* were sacred places, corresponding to the Polynesian *marae*, and some if not all of the statues were erected in honour of ancestors.

The statues were cut from compressed volcanic ash, a soft and easily worked stone. All conform to a single distinctive type, representing only the upper half of the body with an upturned face and long ears, but vary in height from 3 ft to 36 ft. One example has even been found in the quarry with a length of 66 ft., but it had never been moved. The usual height of the images on the *ahu* was from 12 ft to 20 ft., and they were surmounted by tall cylindrical hats or crowns (as much as 6 ft high and 8 ft in diameter) in proportion. These consisted of a red volcanic tuff and were quarried in a different crater from the statues.

The quarry for the statues was both inside and outside the large crater of the volcano called Rano-raraku at the northeast end of the island, there they are found in large numbers and in all stages of completion, as though the work had been suddenly interrupted and never afterward resumed. The sculptors worked in niches surrounding the statues, and the carving was completed before the back was detached by undercutting. The stone chisels used were found in situ and are of two main types. The rougher kinds somewhat resembling a European Palaeolithic hand axe, occur in large numbers and were evidently employed for roughing out the contours of the figures. The finer kinds, of hard stone, are without shaped butts and resemble the adzes of western Polynesia and New Zealand more closely than eastern Polynesian types. The tapered spearheads of flaked obsidian are peculiar to the island. Apart from the statues on the *ahu* and in the quarry, there are a large number standing about the slopes of Rano-raraku facing westward, others in isolated positions, and a series placed at intervals along an ancient processional road running westward from the quarry for 6 mi. This road, and two others less distinctly visible, probably served for transporting the statues. It is about ten feet wide and levelled by shallow cuttings and embankments.

The means of transporting the larger images, the heaviest of which must have weighed about 50 tons, has never been satisfactorily explained. But a native account states that they were dragged into position (presumably with ropes, the native hemp and hibiscus fibre furnishing adequate materials) and that round pebbles were placed underneath to serve as rollers. Seaweed may also have been used to minimize friction with the ground. The statues were probably erected on the *ahu* by being hauled up an incline of earth or stones and then gradually up-ended into position by withdrawing the supporting material from under their bases.

Habitations, though generally constructed of perishable materials, were sometimes provided with wrought foundation stones, resembling corbustones, sunk into the ground and provided with holes in their upper surface for inserting the wooden rods which provided the framework of the houses. Their ground plan was long, narrow and boat-shaped, and they were large enough to accommodate from 10 to 30 persons. There are also remains of stone chickenhouses, and of round-chambered towers on the coast used as fishing lookouts. Natural caves were widely used as habitations, frontal walls supplementing some.

Apart from these houses, there is one sacred valley at the south-west corner of the island, called Orongo, situated in a romantic position on a narrow and precipitous ridge between cliff and crater. It contains 48 houses built entirely of stone, the only examples of their kind in Polynesia. They were roofed by partial corbeling and a flat capstone, over which earth was heaped. Their low and narrow interiors, illuminated only by small doors, were often decorated with designs and figures in colour.

This village was connected with a bird cult (still remembered) which played an important part in native life. A leading feature was an annual competition to secure the first egg and on an outlying islet by the migratory sooty tern. Orongo was occupied by the competitors, and the numerous rock carvings in the vicinity depicting a bird-headed man, sometimes holding an egg in his hand, presumably commemorate the victors. The rock carvings, some much weathered, also depict faces and geometric designs.

There can be little doubt that the stone structures of Easter Island are the work of the ancestors of the present native inhabitants (reduced in numbers to 150 in 1944). The statues and platforms were actually in use at the time of discovery, and some of the sculptors' names are still remembered. But apart from traditional evidence, the occurrence of certain peculiar designs carved on the backs of some of the stone statues, as well as on small wooden figures of recent date, furnishes an unquestionable link between past and present culture.

Date of Settlement.—The date of the earliest settlers' arrival, their point of departure and the question whether there was more than one migration are still uncertain. Tradition states that the ancestors arrived, under a chief named Hotu-matua, in two canoes coming from the west, but supplies no clear evidence of previous inhabitants or of subsequent immigrations. On the basis of the shortest recorded genealogy of 22 chiefs descended from Hotu-matua, migration can hardly be assigned to a period later than the 14th century A.D., and although the monuments contain no evidence for accurate dating, their number and the weathered condition of many of them indicate an age of many centuries. There is no evidence of a succession of cultures.

Racial and Cultural Affinities.—Racially and linguistically there is no doubt that the Easter Islanders are predominantly Polynesian, with a considerable Negroid admixture. The skulls collected from graves supply corroborative evidence. It seems simpler to ac-

count for the Negroid element by presuming that the racial intermixture occurred in Melanesia previous to the arrival of the settlers than by postulating an earlier migration of Melanesians to Easter Island. Nevertheless, Hotu matua's migration may have been preceded by another, also of Polynesian stock, but with a stronger infusion of Melanesian blood and culture. This would help to explain the social dualism and clan antagonisms to which some of the traditions bear witness. Attention has also been called to a number of remarkable resemblances in the bird cult and the art associated with it as between Easter and the Solomon Islands, these seem almost to amount to proof of a special cultural affinity.

Script.—The writing engraved on wooden tablets, unique in Polynesia and first noted in 1884, is undoubtedly of considerable antiquity. It takes the form of pictographs (or ideograms), representing stylized figures of men, birds, fish, etc., arranged in the inverted position of alternate lines (boustrophedon), so that the reading of a tablet is obliged to turn it upside down at the end of each line. The figures seem to have served as mnemonic symbols and cannot be translated word for word. Some of the stories which the tablets record have been obtained from living natives, but the exact meaning of the symbols and method of interpretation have been lost, probably beyond recovery.

Bibliography.—One of the most exhaustive bibliographies on Easter Island yet published appears in Alfred Métraux's monograph *Ethnologie of Easter Island*, B. P. Bishop Museum, Bull. 100 (Honolulu, 1940). (H. J. Br. X.)

EASTERN QUESTION, THE The expression used in diplomacy from about the time of the Congress of Verona (1822) to comprehend the international problems involved in the impending dissolution of the Turkish empire. Its use in this narrow sense is a result of the conditions in which it was invented. In the early 19th century the Ottoman empire was still the only east with which European diplomatists were collectively brought into contact, for the questions of the middle and far east had not yet arisen.

The Eastern Question—though its roots are set far back in history, in the ancient contest between the cultures of Europe and Asia, the antagonism of Christian and Moslem and the perennial rivalry of the powers for the control of the trade routes to the orient—dates in its modern sense from the treaty of Kuchuk Kamardji (1774), which marked the establishment of Russia as a Black sea power and formed the basis of Russia's special claim to interfere in the internal affairs of the Ottoman empire. The actual right conceded was, however, very limited. Article vii of the treaty runs "The Sublime Porte promises to protect firmly both the Christian religion and its churches, and also permits the minister of the imperial court of Russia to make on all occasions representations in favour of the new church in Constantinople, and of those who carry on its services." In view of later Russian claims, the wording of this article is important.

The compact between Napoleon and Alexander I of Russia at Tilsit (1807) marked a new phase, which culminated in the treaty of Bucharest (1812). By this instrument the Russian frontier was advanced to the Pruth and to the northern or Kilia branch of the Danube, and Russia's claim to intervene between the sultan and his orthodox subjects received a new sanction in article v, which confirmed "the contracts and conventions which had been counted among the privileges of Moldavia," and in article viii, which stipulated for certain concessions to the insurgent Serbs.

The attitude of the various powers in the Eastern Question was now defined. Russia, apart from its interest in the Orthodox subjects of Turkey, aimed at owning or controlling the straits which were Russia's only outlet to the Mediterranean and the ocean beyond. Austria, once the champion of Europe against the Turk, saw in Russia's advance a greater danger than any to be feared from the moribund Ottoman power, and made the maintenance of Turkey's integrity a prime object of its policy, thus agreeing with Great Britain, whose traditional friendship with Turkey was strengthened by the rise of a new power whose rapid advance threatened British communications with India and the stability of British rule there. But though Austria, Great Britain and presently France were all equally interested in maintaining the Ottoman empire, the failure of the Congress of Vienna (1815) to take action regarding the guarantee of Turkey seemed to endorse Russia's claim to regard the Eastern Question as its "domestic concern" in which Europe had no right to interfere.

This was a result of the sultan's obstinate refusal to ratify the treaty of Bucharest. As Castlereagh put it, it was impossible to guarantee territories of which the boundaries were in dispute.

The Greek Revolt—When, in March 1821, the news reached the Powers assembled at the Congress of Laibach that Prince Alexander Hyspanli, a Greek officer in Russian service, had crossed the Pruth and raised the standard of revolt in the Danubian Principalities, it was feared that his claim to have Russian support was well founded. The Emperor Alexander I, however, yielding to Metternich's influence, repudiated Hyspanli's action, and the revolt, unsupported by the Rumanian people, collapsed.

It was different, however, when, on April 7, Archbishop Germanos of Patras raised the standard of revolt in the Morea, here the Greek population rose *en masse*, massacred the Muslims and by September had completed the liberation of the peninsula by capturing the capital, Tripolitza. The revolt now spread north of the Isthmus, and, above all, to the Greek islands, whose loss—since they were the only recruiting grounds of the Ottoman navy—deprived Turkey of the command of the sea, thus frustrating all efforts to suppress the rising until the intervention of Mehemet Ali of Egypt at the end of 1824.

The unexpected success of the insurgents threatened to produce a European crisis, for the heinous reprisals of the Turks, culminating in the execution of the Orthodox Patriarch Gregorios (April 22, 1821), roused intense feeling in Russia and it needed the united efforts of Castlereagh and Metternich—who met at Hanover in October—to persuade the Emperor Alexander not to stultify his mission as the peace maker of Europe by intervening in Turkey.

The accession of George Canning to office (Aug. 1822) made no immediate change in British policy, but in March 1823 he recognized the belligerency of the Greeks, in order to make their provisional Government responsible for their piracies. It was not, however, until Sultan Mahmud appealed to his vassal, Mehemet Ali of Egypt, to assist him with his trained army and fleet, that the Powers made any concerted effort to influence the situation.

The Emperor Alexander now proposed that the Powers should impose a settlement on the basis of Greek principalities tributary to the sultan. Metternich, who took this as implying an extension of Russian influence, countered by proposing an independent Greek State. A conference was summoned at St. Petersburg, but, as the majority favoured collective intervention, on a principle which Great Britain had always opposed, the British representative was withdrawn, and the meeting resulted in nothing but a futile offer of mediation (March 25, 1825).

Mehemet Ali Intervenes—Meanwhile Ibrahim, Mehemet Ali's adopted son, had landed at Modon and begun the systematic conquest of the Morea. His fleet commanded the sea, and on land the Greek guerrilla fighters had no chance against the trained Egyptian troops, only the heroic defence of Missolonghi (May 1825–April 1826) relieved the gloom of this terrible year. The death of the Tsar Alexander I (Dec. 1, 1825), however, changed the European situation. His successor, Nicholas I, had begun his reign by quelling a serious mutiny of the troops, and a war with Turkey seemed an admirable way of restoring the morale of his army. A step in this direction was taken when, at the outcome of the Duke of Wellington's congratulatory mission to the new tsar (Jan. 1826), a protocol was signed at St. Petersburg under which Great Britain and Russia were to offer their mediation with a view to a settlement on the basis of tributary principalities, and if the mediation were rejected, the Powers might take action "jointly or separately."

Nicholas now sent an ultimatum to the Porte, demanding the execution of the terms of the Treaty of Bucharest, and since the sultan had just massacred the Janissaries (*g v*) Turkey could not resist. On Oct. 1 was signed the Treaty of Akkerman, which conceded all the Russian claims.

The Treaty of London—This action of Russia, together with the barbarities of Ibrahim—who threatened to depopulate Greece and colonize it with fellahs and negroes—stirred the other Powers to activity. A conference met in London and on July 6, 1827, the Protocol of St. Petersburg was turned into the Treaty of London. This treaty Austria and Prussia refused to sign, and the settlement of the Greek Question therefore passed into the hands of Great Britain, France and Russia, who engaged to procure the autonomy of Greece under the sultan's suzerainty. There was to be

no breach of friendly relations with Turkey, but should the sultan refuse mediation, the Powers were to send consuls to Greece. Meanwhile, an armistice was to be proposed to both sides, to be enforced by such means as might "suggest themselves to the prudence" of the contracting Powers. The readiest means seemed to be a "peaceful blockade" of Ibrahim in the Morea.

Navarino and the Russo-Turkish War—On Oct. 20, in order to bring peaceful pressure on Ibrahim, who had rejected the armistice, Admiral Codrington sailed the allied fleet into the Bay of Navarino, where the Turco-Egyptian fleet lay at anchor. A chance encounter led to a general engagement and the total destruction of the Ottoman navy. The British Government tried to explain away this "unlucky event", but Sultan Mahmud refused to regard the demonstration as "peaceful," and proclaimed a holy war. The Emperor Nicholas seized the occasion and there followed the Russian invasion of Turkey, which ended with the Treaty of Adrianople (1829). The other Powers, meanwhile, feared that Russia would thus secure her influence over liberated Greece, and in July 1828 Britain, France and Russia signed the Protocol of London, by which France was entrusted with the task of ousting Ibrahim from the Morea. By the time the French troops arrived, however, this object had already been achieved by a naval demonstration by Codrington at Alexandria. By a protocol signed at London on Nov. 16, 1828, the conference placed the Morea and the Cyclades under the guarantee of the three Powers, this guarantee being extended on March 22, 1829—after General Church's victories over the Turks north of the Isthmus—to the mainland south of the line Arta-Volo and including the island of Euboea. These territories were to be erected into a tributary principality governed by a prince chosen by the Powers.

The Russian victory and the fact that the terms of the Treaty of London were embodied in the treaty of Adrianople led the other Powers to acquire momentum by insisting on further concessions. On Feb. 3, 1830, a protocol of the London Conference settled that Greece should be an independent principality and be offered to Leopold of Coburg (afterwards King of the Belgians). Leopold having refused the honour another protocol laid down that Greece should be an independent sovereignty, extended the frontier to the line Arta-Volo and proposed Prince Otto of Bavaria as its ruler. King Louis of Bavaria accepted the offer on behalf of his young son, but stipulated that he should be king. This was agreed, and on May 13, 1832, another Treaty of London (antedated the 7th) was signed, placing the new Kingdom of Greece under the guarantee of the three Powers. (See *GREECE: Modern History*.)

Revolt of Mehemet Ali—The Greek question was still unsettled when a new phase of the Eastern Question was opened by the revolt of Mehemet Ali, pasha of Egypt. The immediate occasion, though not the pretext for his revolt, was the sultan's refusal to give him the pashaliks promised as the price of his intervention in Greece, he feared, too, that if he waited till the reform of the Turkish army was completed, he would share the fate of Hussein of Bosnia and Mustafa of Scutari, whom the sultan had crushed in the spring of 1831. On Nov. 1, 1831, accordingly, an Egyptian force entered Syria, met the fleet under Ibrahim at Jaffa, and at once besieged Acre. The garrison's resistance delayed the Egyptian advance, at Constantinople efforts were made to persuade the sultan to come to terms, and only in May 1833 was the ban of outlawry launched against Mehemet Ali. Meanwhile, Ibrahim had been pushing on. He had already occupied Gaza and Jerusalem before Acre fell (May 27). On June 15 he was in Damascus. On July 9 and 11 he defeated the Ottoman advance guard at Homs and Hamah, and on the 17th crushed the main Turkish army, under Hussein Pasha, at the pass of Belan. Pushing on into Anatolia, he gained a crowning victory at Konia over another Ottoman army under Reshid Pasha (Dec. 23), and advanced to Afium-Karhisar and Kutayah. Nothing lay between him and Constantinople but the uncertain attitude of the Powers.

After the first defeats Sultan Mahmud, in his rage and despair, had turned first to Great Britain for aid. But, though Stratford Canning wrote from Constantinople, urging the necessity for upholding the sultan's authority even by arms, Palmerston was not prepared for an isolated intervention which would involve a breach

with France and Russia. The news that no active aid could be expected from England was followed by that of the disastrous defeat at Koma, which chanced to coincide with the arrival in Constantinople of a special Russian envoy, Count Muraviev, who at once renewed the tsar's previous offer of ships and troops to protect the capital. The sultan, in desperation, accepted, and on Feb. 20, 1833, a Russian squadron entered the Bosphorus.

The French and British representatives had in vain tried to persuade Mahmud to reverse his fatal decision. They now agreed to take a new line, and induced the Porte to invite the Russians to withdraw by undertaking that France would persuade Mehemet Ali to accept the Sultan's terms. But the Emperor Nicholas sent peremptory orders for his fleet to remain until Ibrahim should have recrossed the Taurus mountains, and Mehemet Ali scornfully rejected the sultan's offers, he insisted on his full demands—Syria, Ichel, Aleppo, Damascus and Adana. The two Western Powers, intent on getting the Russians away, now pressed the Porte to yield, and, as the result of this combined pressure on both sides, and incidentally of a famine in the capital, an arrangement was reached. On April 8 was signed the Convention of Kutayah, under which all the Egyptian demands were conceded. The immediate result, for the Powers, was to throw Turkey wholly into the arms of Russia. Russia had given the sultan deeds, not words, and to Russia he committed himself. Before the Russian forces left there was signed in the palace of Unkar Skelessi the famous treaty (June 8, 1833) which, under the guise of an offensive and defensive alliance, practically made Russia the custodian of the gates of the Black sea.

This temporary settlement was nowhere expected to prove permanent. Sultan Mahmud dreamed only of revenge, and engaged German officers—Moltke among them—to reorganize his army. The crisis came in 1838. In 1834 the Syrians had revolted against Mehemet Ali's tyranny, now the Arabs of the Hauran were in arms. The sultan, urging that he must rescue his subjects from oppression, could no longer be restrained, and on April 21, 1839, the Ottoman army invaded Syria, only to meet with a crushing defeat by Ibrahim at Nezib (June 23). Before the news reached Constantinople the old sultan died (July 1), leaving his throne to Abd-ul-Mejid, a lad of 16.

Finally, the news reached the capital that Ahmed Pasha, the Ottoman admiral-in-chief, had handed over his fleet to Mehemet Ali, on the pretext that the sultan's advisers were sold to Russia. So far as the Ottoman empire was concerned, Mehemet Ali was now master of the situation. He had, however, to walk warily.

At the outset these showed an apparently united front, the ambassadors of the five Powers on July 27 presenting a joint note to the Porte, in which they declared that an agreement had been reached in the Eastern Question and urged the Ottoman Government "to suspend all definite decision made without their concurrence." But the Powers were actually agreed only on the need for agreement. Britain, especially, insisted on this, for she feared

desert had been placed between the pasha and the sultan. The deadlock thus created developed into a crisis when, on Feb. 20, 1840, Thiers came into power in France. Not only did he reject a compromise which, on May 7, Guizot, as French ambassador, arranged with Palmerston, but it presently transpired that, without openly breaking with the concert, and without informing the other Powers, he was encouraging a "direct arrangement" between Mehemet Ali and the Porte. The discovery of what seemed an underhand intrigue by France to secure her "complete individual triumph" at Constantinople and Alexandria, led at once to a strong countermove from the other Powers, who on July 15, without the concurrence of France, signed with the Porte a Convention for The Settlement of the affairs of the Levant. By the instrument it was agreed that, the terms to be given to Mehemet Ali having been arranged with the Porte, the signatory Powers would force the pasha to accept them. If he yielded within ten days he was to receive the hereditary pashalik of Egypt, the administration of southern Syria for life and possession of the fortress of Acre. After ten days the offer of Syria was to be withdrawn, and after another ten days the sultan was to be free to take such action as his own interests and the counsels of his allies might suggest.

The news of this "mortal affront" caused immense excitement in Paris, and Thiers, declaring that the alliance with Great Britain was shattered, hurried on preparation for war. The immediate effect was that Mehemet Ali, confident of French assistance, maintained a defiant attitude. The unexpected outcome of the armed intervention of the Powers, however, soon changed the situation. The allied fleet, under Sir Charles Napier, had hardly appeared off Beirut (Aug. 11) when the Syrians rose in revolt against Ibrahim's tyranny. On Sept. 11, Suleiman Pasha not having obeyed the summons to evacuate the town, the bombardment of Beirut began. On Oct. 3 the town fell, and Ibrahim, cut off from his communications by sea and surrounded by a hostile population, began a hurried retreat. On Nov. 3, Acre surrendered to the allied fleet. The Legends of Mehemet Ali's invincibility and humane and enlightened rule were now pricked bubbles. The only question was whether he should retain Egypt.

Already, on Sept. 15, the sultan had, in accordance with the terms of the Convention of London, declared him deposed. But the news of this, and of the events in Syria, produced an exceedingly dangerous temper in France, there was loud clamour for war, and it looked as though the pacific Louis Philippe were faced by the alternative of war or revolution. To most of the British cabinet it looked as though concessions must be made to France for the sake of European peace. Therefore, when Guizot, on Oct. 8, presented to Palmerston what was practically a French ultimatum, "it was determined that this intimation should be taken in a friendly spirit," and that Palmerston should come to an agreement with the ministers of the other Powers jointly to persuade the Porte not to insist on depriving Mehemet Ali so far as Egypt was concerned. This did not at once stop the war fever in Paris, but Louis Philippe did not want war, the dismissal of Thiers, and the appointment of Guizot as foreign minister in the new Government under Marshal Soult, made for more moderate counsels, and by Dec. 4, the danger was past.

Nine days earlier Sir Charles Napier had appeared with the British squadron before Alexandria and had induced Mehemet Ali to submit to the sultan and restore the Ottoman fleet, in exchange for a guarantee of the hereditary pashalik of Egypt. Gentle pressure by the combined Powers on the Porte did the rest. On Feb. 13, 1841, the sultan issued a *firman* appointing Mehemet Ali hereditary pasha of Egypt, a second *firman* of the same date investing him with the government of Nubia, Darfur, Kordofan, Sennar and their dependencies.

The Crimean War.—The Russian policy, initiated in 1829, of maintaining the integrity of Turkey while practically treating her as a vassal state, ended in 1841, the Emperor Nicholas reverted to the idea of expelling the Turks from Europe. The Eastern Question, however, slumbered for a while, the European Powers being fully engaged with the troubles which culminated in the revolutionary movements of 1848-49. In 1850, however, a new and fateful phase developed. Under the capitulations of

short, he announced through the Russian ambassador in London, Baron Brunnow, that he was prepared to accept the British views on the Turco Egyptian question, to allow the Treaty of Unkar Skelessi to lapse, and to act in the Ottoman empire only in concert with the other Powers, in return for an agreement closing the Dardanelles to the warships of all nations. Brunnow was empowered to arrange a coalition to settle the Egyptian question.

To this proposal all the Powers agreed, including France, and for nearly a year negotiations continued. In France public opinion violently supported Mehemet Ali's claims, while Palmerston believed that the Ottoman empire would never be secure until "the

1740 France held the right to protect the Catholics in Turkey and the guardianship of certain holy places in Palestine. These rights had been in abeyance since the French Revolution and Russia had assumed the guardianship of the holy places. But Louis Napoleon, now Prince President of the French Republic, desiring to conciliate the clergy and to increase his prestige, instructed his ambassador in Constantinople to demand the restoration of French property and rights in the holy places. The Porte appointed a mixed commission to enquire into the matter, but since France objected to any documents being considered of later date than 1740 (which would have excluded the Treaty of Kuchuk Kainardji) and Russia peremptorily demanded that no change should be made, no mutually satisfactory solution was possible, and on Nov. 4, 1851, the British ambassador, Stratford Canning, reported to his Government that the question had "as sumed a character of extreme gravity." It had developed into a struggle between France and Russia for influence in the East.

In vain the Ottoman Government suggested various compromises. Napoleon, now Emperor of the French, needed a war, and the Emperor Nicholas' refusal to recognize him as an equal embittered him against Russia. Nicholas, too, thought the moment opportune for carrying out his plans for ousting the Turks. He believed that he could rely on the neutrality of Austria, out of gratitude for his assistance to her in crushing the Hungarian insurrection in 1849. Great Britain's benevolence seemed to be assumed when the pacific Lord Aberdeen became prime minister in Dec. 1852. The tsar even revived his earlier idea of an arrangement with Great Britain for the partition of Turkey. In the famous conversations (Jan. 9 and 14, 1853) with the British ambassador at St. Petersburg, Sir Hamilton Seymour, he spoke of Turkey as the "Sick Man," and gave his ideas as to the disposal of its inheritance. The Balkans should be divided into a series of Christian States, Great Britain receiving compensation in Egypt, Cyprus and Crete. The comment on this by Lord John Russell, on behalf of the British Government, was to deny that Turkey was sick, and to insist that the whole question must be settled by general agreement. But Nicholas was deceived by the hesitations of Aberdeen, who was hopelessly divided between his fear of Russia and his dislike of the Turks, he was deceived, too, by his ambassador, Baron Brunnow, who reported that in England the pacific influence of Bright and Cobden was supreme. Accordingly, after ordering the mobilization of his forces, he despatched Gen. Meshikov to Constantinople with an ultimatum demanding the preservation of the *status quo* as regarded the holy places and Russia's right to protect Christians in Turkey.

Meshikov, a blustering soldier, reached Constantinople on April 19, but the crisis was delayed by the diplomacy of Lord Stratford de Redcliffe, the British ambassador, who persuaded the Porte to yield respecting the holy places, but to resist the demand for a protectorate over the Christians.

On May 5, arguments and threats having failed, Meshikov presented the ultimatum, on the 22nd the Porte rejected it. This meant war, and on June 22 the Russians crossed the Pruth and proceeded to occupy the Principalities.

This was met by a collective protest of the Powers, and Austria concentrated her forces on the Serbian frontier. In these circumstances Russia agreed to a conference, which met at Vienna in August. The four points on which the other Powers insisted were (1) the substitution of an international for a Russian protectorate of the Principalities; (2) freedom of navigation on the Danube; (3) maintenance of the integrity and independence of Turkey; and (4) renunciation by Russia of her claim to protect the orthodox subjects of Turkey. The conference drafted a convention, to be proposed to Russia by the Porte, confirming the rights granted by the treaties of 1774 and 1829 and by the *fermans* recently issued, and conceding to the orthodox rite a share in all privileges, etc., granted to other Churches under the Capitulations. Russia accepted this on condition that no modifications were made "under bellicose influences." But when, on Aug. 19, the Porte accepted the draft, it was with an amendment reserving to the sultan the right to protect the Christians. This amendment the tsar refused to accept, and, since this seemed to show that

he intended to press his extreme claims, the British fleet was ordered to pass the Dardanelles, ostensibly to protect the sultan from the danger of a Muslim rising. The British Government announced that no aggressive action would be taken unless the Russians crossed the Danube or attacked an Ottoman port on the Black sea. The immediate *cassus belli* which opened the Crimean War was the destruction by the Russian fleet of an Ottoman squadron in the harbour of Sinope on Nov. 30, 1853. On Jan. 3, 1854, a combined British and French squadron entered the Black sea, it was not, however, till March 27 that France and Great Britain declared war against Russia.

The Russians now advanced into the Balkan peninsula, but on June 3 an Austrian ultimatum forced them to retire not only from the Balkans, but from the Danubian Principalities which Austria occupied. Although the immediate menace to Turkey was thus removed, the Allies determined to continue the war and to secure the acceptance of the Four Points, and on Sept. 14 their combined armies landed in the Crimea. (See CRIMEAN WAR.) The initial disasters of the war bent the stubborn resolution of the "Iron Tsar," and on Nov. 28, strongly urged by Frederick William IV of Prussia, he consented to accept the Four Points. It was too late. The successes of the Allies were bringing them fresh strength. On Dec. 2 Austria signed with them a formal defensive alliance, and in Jan. 1855 Cavour's determination to secure a position for the Kingdom of Sardinia in the councils of the Powers brought the Piedmontese into the Allied camp. On March 2 the Emperor Nicholas died, and the succession of Alexander II seemed to promise peace. Conferences were resumed at Vienna, but honour and prestige were involved on both sides, and the war dragged on. The fall of Sevastopol (Sept. 9) might have been taken as decisive, but it was not till December that an Austrian ultimatum persuaded the tsar to yield. The terms of peace were to be settled by a congress in Paris.

The Treaty of Paris was signed on March 30, 1856. By this instrument the Eastern Question seemed to be settled, in the sense desired by the Allies. By the cession of a portion of Bessarabia, Russia was thrust back from the mouths of the Danube, of which the navigation was declared free, Russian naval power was destroyed in the Black sea, which was made neutral, the right of Russia to intervene in Turkey was formally repudiated, and the Ottoman empire, in return for elaborate promises of reform, was admitted to the concert of the Powers. Wallachia and Moldavia, with their existing privileges, were placed under the collective guarantee of the Powers, while remaining under the suzerainty of the Porte. It was not till three years later that the union of the Rumanian nation was accomplished by the election of John Alexander Cuza as prince in both principalities.

The Russo-Turkish War, 1877-78.—It was to be expected that Russia would seize the first opportunity of repudiating the humiliating terms thus imposed upon her. This came in 1870, and she took advantage of the collapse of France to denounce the Black sea clauses of the Treaty of Paris. The action of the Conference of London in regularizing this proceeding prevented any immediate critical developments. But though for five years longer the Eastern Question was to remain quiescent, beneath the surface it was exercising a strong and disturbing influence on the relations of the Powers. In spite of the League of the three Emperors, founded in 1872, Austria and Russia were once more hatching rival plans of aggression in the East. Russia was determined to seize the first opportunity for recovering the lost strip of Bessarabia and so removing the last tangible results of the Crimean War, while Austria, encouraged by Bismarck—who wished to reconcile her to her depositions as a German Power—was hoping to find in the Balkan peninsula compensation for her losses in Italy and Germany. Behind the Russian policy was the Pan Slav ideal, which Russian agents were busy propagating among the Balkan peoples, behind the Austrian policy was the conviction that Serbia was already aspiring to play the part played by Piedmont in Italy, and to become the head of a Southern Slav empire built up out of the ruins of the Austrian and Ottoman empires. If the rivalry between Russia and Austria did not lead to a breach, this was because Russia saw that in the event of

war Germany would have to support Austria, now once more regarded as the bulwark of Germanism against the Slavs, while Austria feared that such an alliance would merely add to the overgrown power of Germany. As for Bismarck, who was preoccupied by the reviving power of France, the last thing he wanted was a war with Russia. It was such considerations as these which determined the attitude of the three Powers when the next critical phase of the Eastern Question began.

It opened in July 1875, when the Christian Slavs of Hercegovina rose against Turkish misrule. The failure of the Turks to suppress the insurrection and the consequent danger of a general conflagration led to the intervention of the Powers, and on Dec. 30, 1875, Russia, Germany and Austria-Hungary agreed to the terms of a joint note, drawn up by Count Andrassy, for presentation to the Porte. This declared that the time had come for joint action to compel Turkey to translate her promises of reform into acts. It demanded the formal recognition of the equal status of the Christian religion, and certain reforms in Bosnia-Hercegovina which were to be watched over by a mixed commission of Christians and Muslims. Great Britain and France having adhered, the "Andrassy Note" (q.v.) was presented to the Porte on Jan. 31, 1876.

The sultan, as usual, promised everything and performed nothing. Meanwhile the revolt spread. In May the signs were ominous, Serbia was arming and Prince Milan gave the command of his troops to the Russian general Chernayev, Montenegro also was arming. The three emperors thought it time to take action and on May 13 signed the Berlin Memorandum, which proposed combined action of the fleets, the enforcement of a two months' armistice, and further action if no settlement were reached. This broke down on the opposition of Great Britain, Disraeli arguing that it would only encourage the insurgents to go on. On May 24 the British fleet was ordered to Besika bay, for the defence of Turkey in case of need. On June 30 Serbia declared war on Turkey, and on July 2 Montenegro followed suit. On July 8 the Emperors Alexander II and Francis Joseph met at Reichstadt and signed a convention defining the policy of Austria and Russia. There was to be no intervention so long as the contest was undecided. In the event of the defeat of Serbia, the two Powers would combine to preserve the *status quo*. In the event of her victory, Austria-Hungary was to receive Bosnia-Hercegovina and Russia the ceded portion of Bessarabia. This agreement, which was significant in the light of later events, secured the neutrality of Austria-Hungary during the forthcoming Russo-Turkish War.

Meanwhile a fresh complication had arisen. In May the Bulgarian peasants had also risen and massacred many Turkish officials. The Turks, on their march northwards against the Serbs, took horrible vengeance, and the news of the "Bulgarian atrocities" caused immense excitement in England, and more especially in Russia. The Serbs, too, were soon in danger of being overwhelmed, and it was only a Russian ultimatum that prevented the Turks from advancing on Belgrade. In August the British Government, which wished to prevent the isolated action of Russia, persuaded Prince Milan of Serbia to ask for the mediation of the Powers, and took advantage of this to urge the Porte to come to terms with the Serbs and Montenegrins, for fear of a worse thing. This attempt at mediation, however, broke down at the obstinacy of both the Serbs and Turks. The Serbs were feeling increasingly certain of Russian support, as for the Turks, the deposition of Sultan Abd-ul Aziz in May, and of his imbecile successor Murad in August, had infused a new spirit into their government, for the astute and ruthless Abd-ul-Hamid II was now sultan. His policy was to pose as a reformer, and, for the rest, to procrastinate in the hope of splitting the European concert. He countered a British proposal for a comprehensive scheme of reforms in the Ottoman empire, to be embodied in a protocol concluded between the Porte and the Powers, by issuing an elaborate scheme himself (Oct. 12). But the patience of Russia was now exhausted, on Oct. 15 Gen. Ignatiev arrived in Constantinople, and on the 31st presented an ultimatum demanding the conclusion of an armistice with Serbia within 48 hours. On Nov. 2 the Porte yielded, and the field was cleared for fresh

diplomatic action. On the 4th, Lord Derby proposed a conference at Constantinople, on the basis of the integrity of Turkey. All the Powers accepted, but on the 8th the Emperor Alexander declared publicly that, if the Powers did not at once take effective measures in concert to enforce reforms, he would act alone.

The conference opened on Dec. 31, but it was soon clear that the Porte had no intention of accepting its decisions. On the 11th a constitution for the Ottoman empire was solemnly proclaimed, and the Porte rejected the demands of the conference on the ground that they must now be submitted to the new parliament. The crisis foreseen by the tsar had now arisen, the conference had proved abortive, and when on March 19, 1877, the new Turkish parliament met, almost its only act was to reject the demands presented by Russia. On April 24 Russia declared war.

The events of the war are described elsewhere. (See RUSSO-TURKISH WARS.) So far as the relations between the Powers were concerned, the most critical period was after Gen. Gurko's capture of Adrianople (Jan. 20, 1878), when the Russian advance threatened Constantinople and the sultans. The British Government on Jan. 14 warned the tsar that any treaty between Russia and Turkey which might affect the engagements of 1856 and 1871 "would not be valid without the assent of the Powers who were parties to those treaties," and on the 23rd the British fleet was ordered to Gallipoli. On the 31st the preliminaries of peace between Russia and Turkey were signed at Adrianople, the terms of the armistice allowing the Russians to advance to within a few miles of Constantinople. The Grand Duke Nicholas now pushed forward to the Iincs of Chataldjia, whereupon the British fleet was ordered to enter the Sea of Marmora. The situation was now extremely critical, for Austria-Hungary declared the terms of the Convention of Adrianople to be inconsistent with her interests, and it soon became clear that the only way of peace lay through a European congress. On Feb. 5 Count Andrassy formally invited the great Powers to a conference, and Russia, which was in no condition to continue the war with Great Britain and Austria ranged against her, had perforce to agree.

Before the final arrangements for the congress could be made, however, the Convention of Adrianople was converted into the Treaty of San Stefano (March 3). This seemed to realize the worst fears of the Powers. In default of the payment of a huge war indemnity, Turkey was to cede to Russia, Batum, Ardahan and Kars in Asia, and the Dobruja in Europe—this latter to be exchanged with Rumania for Bessarabia. Serbia, Rumania and Montenegro were to be independent States, Bosnia and Hercegovina were to receive autonomous institutions under the joint control of Russia and Austria-Hungary, above all, Bulgaria was to be erected into an autonomous principality, stretching from the Danube to the Aegean and embracing Eastern Rumelia and Macedonia, and its prince was to be advised for two years by a Russian commissioner supported by an army of occupation.

The news of the conclusion of this treaty, which seemed not only to bar Austrian advance in the Balkans but to be fatal to British interests by giving Russia a crushing preponderance in the East, again brought war very near. But in the end the strong representations of the Powers, backed by the diplomacy of Bismarck persuaded the tsar to consent to submit the treaty to the approaching congress.

This met in Berlin on June 13 and, after heated debates, arrived at a definite settlement a month later. By the Treaty of Berlin, signed on July 13, 1878, the terms of the Treaty of San Stefano were greatly modified. (See BERLIN CONGRESS AND TREATY OF) Its signature was hailed in Great Britain as a great diplomatic victory, the preponderance of Russia in the East had been checked, and Lord Beaconsfield boasted that he had secured "peace with honour," but the treaty represented, in fact, the starting point of the latest and most disastrous phase of the Eastern Question which culminated in the World War.

Three new sovereign States were created by the treaty, Rumania, Serbia and Montenegro, but in the case of the former two at least the boundaries assigned to them left them bitterly dissatisfied. Rumania resented the enforced cession of Bessarabia to Russia in exchange for the less desirable Dobruja, and was

bound sooner or later to cast covetous eyes on Transylvania with its preponderantly Ruman population. Serbia was in even worse case. She received indeed an increase of territory, at the expense of Bulgaria, but other terms of the treaty seemed to have been specially devised to make her dream of a Southern Slav union for ever unrealizable, for the Sanjak of Novi Pazar, which was to be garrisoned by the Austrians but still administered by the Turks, cut her off from Montenegro, while the permission given to Austria-Hungary to occupy and administer Bosnia-Herzegovina gave the Habsburg Monarchy what seemed likely to prove a permanent foothold in the Balkan peninsula. The foreign trade of Serbia (mainly pigs), cut off from access to the sea, was placed almost wholly at the mercy of Austria.

The Union of Bulgaria.—The most fateful of all the provisions of the treaty, however, was the splitting up of the greater Bulgaria created by the Treaty of San Stefano, for this not only kept the Balkan peninsula in a ferment for 30 years, but opened up a new problem, that of Macedonia, which was left to Turkey and, inhabited as it was and is by an inextinguishable mixture of races, was to become a bone of contention between Greeks, Serbs and Bulgarians (see MACEDONIA). As for Bulgaria herself, the artificial severance of East Rumelia could not long endure, and after a period of agitation on both sides of the Balkans, Prince Alexander accepted the offer of the crown of united Bulgaria (Sept. 20, 1885). Union was opposed by Russia, whose efforts to dominate the councils of Bulgaria had been frustrated by Alexander and his ministers, and for this very reason Great Britain now favoured the union, since she saw in a strong Bulgaria the best possible obstacle to the extension of Russian power. Austria-Hungary, on the other hand, had no wish to see a strong barrier erected between her and the coveted seaboard on the Aegean, and Serbia, more especially, resented a growth of Bulgarian power which threatened her own ambitious plans. This led to the Serbo-Bulgarian War of Nov. 1885, and when Prince Alexander crushed the Serbs at the battle of Slivnitsa, Austria-Hungary interposed to save Serbia from extinction. British influence at Constantinople, however, obtained from the sultan the formal recognition of the union of the Bulgarians. But the breach between Prince Alexander and the tsar was irreparable, and led to the abdication of the prince (Sept. 7, 1886) and the election of Prince Ferdinand of Coburg in his place. The new prince, who had been an Austrian cavalry officer, was not acceptable to Tsar Alexander III, who refused to recognize him, strained relations continued between Bulgaria and Russia, and it was not till 1898, under Tsar Nicholas II, that the two courts were reconciled (See BULGARIA History).

The Greek War, 1897.—The union of Bulgaria had aroused among the Greeks too much excitement and heart burning, the Cretans proclaimed their union with the kingdom, and only a blockade by the Powers prevented Greece from declaring war on Turkey. The crisis was thus timed over for the time, but in 1894 a secret society known as the *Ethniki Hilaria* (National Society) was founded, among whose objects were the union between the Greek islands and the kingdom, and the encouragement of the Greek movement in Macedonia, in order to prevent its absorption in Bulgaria. When, in 1896, the Cretans again revolted, the influence of this society was enough to compel King George of Greece to take up their cause. The rival forces of the Powers forced the submission of the Cretans to the arbitration of Europe, but on the mainland the excitement continued, Greek irregulars were raiding into Thessaly, and in April 1897 the sultan, encouraged by the German emperor, declared war on Greece. The result was not long in doubt. The Greeks were no match for the Turkish forces, reorganized by German officers, and but for the Powers who imposed an armistice on both combatants (May 20), their ruin might have been complete. As it was, the war was a disaster for Greece. It discredited the dynasty, and by the terms of the peace treaty, signed in December, Greece had to cede a strip of Thessaly and pay a huge war indemnity (See GREECE Modern History). One gain, however, was made. Though Germany and Austria-Hungary had seceded from the European Concert in the Eastern Question,

and in spite of the critical situation as between France and Great Britain arising out of the Fashoda incident (see AFRICA, SUDAN), France, Great Britain and Russia had continued to act together in the Cretan question, had forced the Porte to withdraw its officials from the island, and on Nov. 14, 1897, had invited Prince George of Greece to act as high commissioner.

German Influence in Turkey.—The breach in the Concert of Europe in the Cretan question was significant of profound changes in the grouping of the Powers. So far as the Eastern Question was concerned, a new factor of supreme importance had been introduced. Germany, so long as Bismarck was in power, had maintained a disinterested attitude so far as she herself was concerned, though she had consistently encouraged the eastward expansion of Austria. But with the accession of the Emperor William II came a change of policy, the opening of which was marked by the State visit paid by the emperor and empress to Sultan Abd ul-Hamid in Nov. 1889. More than 50 years earlier Moltke had pointed out the opportunities offered by Asia Minor for German exploitation, and the immediate object of the emperor was to forward German economic penetration, and for this and other purposes to establish his influence in Constantinople. His opportunity came in 1894, when the Turks, in their determination to stifle yet another incipient national revolt, began a systematic massacre of the Christian Armenians. All Europe stood aghast at these horrors, repeated year after year. By Art. LXI of the Treaty of Berlin the Porte had undertaken to carry out reforms in the Armenian provinces, under the superintendence of the Powers, and a special responsibility attached to Great Britain in this matter under the secret treaty which had secured her Cyprus. But even without the despairing appeal of the Armenians to treaty obligations which had never been fulfilled, public opinion in England would have forced the British Government to take some action, and in 1896 Lord Salisbury induced the other Powers to unite in urging upon the Porte the carrying out of the promised reform. Since, however, these representations were not followed up by acts, the sole result was to alienate the Turks from Great Britain, and throw them into the arms of Germany. From Berlin there came, not protests, but a signed photograph of the emperor and his family as a birthday gift for the sultan. That was in 1896. The success of the German trained troops in 1897 was followed in 1898 by a congratulatory visit of the emperor to Constantinople. The imperial pilgrimage to the Holy Land and Syria followed. It was inspired by a mixture of orthodox piety and *Realpolitik*, and was crowned on Nov. 8 by a speech at Damascus in which the emperor declared that he would at all times be the friend of the Sultan Abd ul-Hamid, and of the 300 million Mohammedans who revered him as caliph. This, according to Pastor Friedrich Naumann, was said with an eye on the time when a world war would break out, when the Caliph of Islam would once more raise the standard of a holy war and summon Egypt, the Sudan, East Africa, Persia, Afghanistan and India to war against England. The immediate outcome of the emperor's visit to Constantinople was more tangible: the concession of the port of Haïdar Pasha to the "German Company of Anatolian Railways." The idea of directing German capital and German emigration towards Asia Minor and Mesopotamia had taken definite shape. In 1902 it received a further development in the conclusion of a convention for the building of a railway from Constantinople to Baghdad. The contemplated extension of this line to Basra would have linked up Hamburg and Berlin with the Persian gulf, turned the flank of the British trade routes to the East, and secured the economic, if not the political, domination of Germany in the Ottoman empire. The ultimate idea, partly realized on paper during the World War, was the creation of a great Central European Customs Union, forming an "economic area" stretching from the Baltic to the Persian gulf, as a counterpoise to the United States and the British empire (See Gratz and Schuller, *The Economic Policy of Austria-Hungary during the War*, Eng. trans., 1927).

The Macedonian Question.—Meanwhile the question of what was to be done with Macedonia had become acute. All the

new Balkan States claim the reversion of the lion's share of that country of inextricably mixed races, and in order to substantiate their respective claims Greeks, Serbs and Bulgars were busy exterminating each other. The efforts of the Turks to maintain order were worse than useless, and merely led to armed revolts. In 1903 a serious insurrection of Macedonian Bulgars led to the intervention of the Powers, Austria and Russia agreeing on the so called *Muristeg Programme*, reluctantly accepted by the Porte, under which the three *vilayets* of Monastir, Salonika and Kosovo were placed under the supervision of Austrian and Russian civil agents and their gendarmes was organized and commanded by officers appointed by the Powers. The experiment, which had but poor success, came to an end in 1908 with the breach of the *entente* between Russia and Austria and the attempt to substitute for it an Anglo-Russian programme was frustrated by the revolution in Turkey.

The Young Turk Revolution.—This revolution, by which in 1908 Abd ul Hamid and his régime were overthrown, made a profound change in the general situation. The programme of the Committee of Union and Progress, which had carried out the *coup*, appealed to the sentiment of Europe, which welcomed the birth of a liberalized Turkey, established on the basis of nationality without distinction of creed. It was soon clear, however, that the new liberalism was make-believe, while the new nationalism threatened to be more intransigent than the old Ottoman overlordship. The whole elaborate system of shams by which diplomacy had sought to disguise the disruption of Turkey was especially threatened, for in the new unified and Europeanized State there would be no room for provinces "occupied and administered" by foreign Powers, like Bosnia-Herzegovina (or possibly Egypt), or for "vassal" states like Bulgaria. Therefore, in order to forestall any attempt of a regenerated Turkey to reclaim what it considered its own, those interested took action. On Oct. 7, 1908, the Emperor Francis Joseph issued a rescript annexing Bosnia-Herzegovina to the Habsburg monarchy. Two days earlier Prince Ferdinand of Bulgaria had proclaimed his independence and assumed the title of king (*tsar*). In July 1909, after the withdrawal of the allied forces, the Cretans proclaimed their union with Greece, though the caution of King Constantine, disallowed this for the time being.

The Italian Turkish War, 1911.—The annexation of Bosnia-Herzegovina, which had only been possible owing to the weakening of Russia in the war with Japan, revealed the breakup of even the pretence of a Concert of Europe in the Eastern Question. Here too the division of Europe between the Triple Entente and the Triple Alliance made itself felt. Russia and France joined in the protest of Great Britain against the annexation of Bosnia-Herzegovina as a violation of the treaties and a blow to the very foundations of international law, but the German emperor proclaimed his readiness to support his ally "in shaming armour" and the protest began and ended in diplomatic notes.

The attitude of Italy was more doubtful. Though a member of the Triple Alliance, she resented the strengthening of Austria's position on the opposite coast of the Adriatic, for the rival ambitions of the Italians, the Serbs and the Habsburg monarchy were now adding an Adriatic question to all the others. Then, too, there was the question of Tripoli, the last remnant of the Ottoman empire in northern Africa still available for Italian expansion. The reversions of this had been reserved for Italy when France had occupied Tunis, but the disquieting activities of the Emperor William II led to suspicions of German designs upon it. The result was a rapprochement between Italy and Russia, advertised in Oct. 1909 by the proposal of the Tsar Nicholas II to pay a State visit to Rome.

The alarms of Italy were increased by the Agadir incident of July 1911, and she determined to take action at once. On Sept. 27, an Italian ultimatum was presented to the Porte demanding its consent to an Italian occupation of Tripoli under the sovereignty of the sultan, on the 29th she declared war on Turkey. But for fresh developments in the Balkans the war which followed might have dragged on indefinitely. But threatened by a new and more instant danger, the Porte suddenly came to terms

By the Treaty of Lausanne (Oct. 18, 1912), Tripoli, Rhodes and the Dodecanese archipelago were, under a thin disguise, ceded to Italy, which thus also obtained a foothold in the Aegean and was brought into conflict with Greek aspirations.

The Balkan League and Balkan Wars, 1912-13.—The new danger to Turkey which led to the hasty conclusion of the war with Italy was the formation of the often mooted league of the Christian States of the Balkan peninsula. In view of their clashing interests, especially in the matter of the reversion of Macedonia, such a league might well have seemed impossible, but the Young Turk revolution, with its threat of a revived spirit of Ottoman national aggression, drew them together, and the rapprochement was encouraged by the split in the concert of the Great Powers. The first step was the conclusion, on March 13, 1912, of a defensive alliance between Serbia and Bulgaria, in which they agreed to take common action in the event of an attack by a great Power upon Turkey and defined their respective claims in Macedonia. A military convention was also signed on May 29.

Meanwhile Greece too had, on May 10, concluded a defensive alliance with Bulgaria, though no mention was made in the treaty of Macedonia, and the Bulgarians, in the event of war arising out of the admission of the Cretan Deputies to the Greek parliament, only bound themselves to observe a benevolent neutrality. This treaty, too, was followed by a military convention (Sept. 22).

The crisis was provoked by a serious rising against the Young Turk régime in Albania. The movement rapidly spread into Macedonia, and the Albanians, flushed with victory, demanded the cession to them of the *vilayets* of Monastir and Skopje, which Greece and Serbia had earmarked respectively as their own. Clearly, if their ambitions were to be realized, it was time for the new Balkan League to intervene. Bulgaria, violently excited by the news of a terrible massacre of Macedonian Bulgars by the Turks, was more than willing to take part. The Powers, appealed to by the League to join in demanding a drastic system of reforms in Macedonia, united only in urging concession upon the Porte and patience on the members of the League, and, when preparations for war continued, they contented themselves with threatening the Balkan States that, if they went to war, the Powers would see that they gained nothing by it. In view of the dislocation of the European Concert it seemed safe to ignore these warnings, and on Oct. 12 Montenegro declared war on Turkey.

The story of the Balkan wars is told elsewhere. (See *BALKAN WARS, 1912-13*.) Here it must suffice to note their outcome. The unexpected collapse of the Turks created a wholly new situation which forced the intervention of the Powers. On Dec. 3, 1912, an armistice was concluded, and on the 13th a conference of the belligerent States met in London to settle terms of peace, the ambassadors of the five Great Powers sitting simultaneously to watch over and direct the settlements. (See *LONDON, CONFERENCES OF*.) The conference broke up on Feb. 1, 1913, as the result of Enver Pasha's *coup d'état* of Jan. 23 which led the Balkan States to denounce the armistice. But one thing it had accomplished. It had been agreed by the Powers that Albania should be erected into an independent principality, and that Scutari should be placed under its sovereignty. Thus, so long as Austria-Hungary held the Adriatic coast, Serbia would be effectually cut off from the Adriatic seaboard and forced into rivalry with Bulgaria and Greece for access to the coast of the Aegean at Salonika. This would lead to the breakup of the Balkan League, which threatened to be a barrier to the eastward pressure of the Central European Powers.

The Treaty of London, signed on May 30, 1913, under the mediation of the Powers, proved less a settlement than the cause of fresh dispute. Crete and all Turkey in Europe beyond the line Enos-Midia were ceded to the Balkan allies, the question of Albania and that of the islands were left to be settled by the Powers. It was inevitable that the victors should quarrel over the spoils, the more so as the creation of an autonomous Albania had profoundly modified the conditions under which the partition treaties between them had been concluded.

The quarrel was precipitated by the complete collapse of new Turkish efforts at resistance. Greece, Serbia and Bulgaria were

alike victorious, but Greece and Serbia by the chances of war, now held the territories which Bulgaria coveted and they showed no disposition to surrender them. Rumunians, too, now joined in the scramble, demanding a rectification of the frontier of the Dobruja, and though on May 7 Bulgaria signed an agreement conceding this demand Rumunians concluded a military convention with Serbia and Greece. The rupture came on the night of June 29, with a sudden attack by the Bulgarians on the Serbs.

The war was soon over, and Bulgaria, utterly defeated, had to submit to hard terms. By the Treaty of Bucharest (Aug. 10, 1912) she ceded Rumunian a considerable strip of the Dobruja, with the fortress of Silistra.

In the south Bulgaria received only a narrow strip to give her access to the Aegean at Didymoteich. She restored Adrianople, Demotika and Kilkis to Turkey. Serbia and Greece, on the other hand, received large accessions of territory. Serbia acquired central Macedonia, including Ohrida and Monastir, Kosovo, and the eastern half of Novi Pazar, the western half going to Montenegro.

Greece obtained Epirus, southern Macedonia, Salonika and the seaboard as far east as Mesiti, thus including the port of Kavala. Crete, too, was soon afterward assigned by the Powers to Greece, together with all the Turkish islands, except Imbros and Tenedos—which command the Dardanelles—and Rhodes and the Dodecanese archipelago, which were in the occupation of Italy.

The Crisis of 1914.—This settlement, as was inevitable, satisfied nobody. Greece desired to round off her territories to the north by acquiring southern Albania, she wished to complete her empire in the Aegean by adding to it Rhodes and the Dodecanese. This brought her into conflict with Italy, which held firmly to the islands, and regarded the new Albanian principality as her peculiar interest. Bulgaria, of course, was profoundly dissatisfied, and her sense of grievance at the settlement—especially the loss of Thrace to Turkey—was not mitigated by the consciousness that the fault was her own. The most fateful outcome of the settlement, however, was the simultaneous strengthening and discomfit of Serbia. Cut off from the Aegean by the Greek occupation of Salonika, it was inevitable that she should aspire to find an outlet to the Adriatic, which could only be done at the expense of the Habsburg monarchy. National irredentism—the vision of the oppressed Slavs of the dual monarchy united with their liberated brethren—combined with economic necessity to throw the Serbs into antagonism to Austria-Hungary. Hence the agitation which culminated in the crime of Sarajevo, the immediate occasion of World War I. Austrian statesmen now saw, or thought they saw, in the rise of the Serbian power, not only a bar to the expansion of the monarchy southwards, but an instant menace to its very existence, and so in July 1914 sent the fatal ultimatum to Belgrade.

The nightmare vision which for more than a century had tormented the cabinets of Europe was now to become a reality. Hitherto it had been possible for the powers to suppress or to isolate the perpetual fires due to the shrinkage of Turkey. Now, suddenly, they had sent out a flame which lighted conflagration in all the world.

With the end of World War I the Eastern Question, in the sense defined, also came to an end, for the Ottoman empire had ceased to exist. It left, however, a plentiful aftermath of questions, some of which—like that of Albania and the Adriatic coast generally—remained dangerous sources of unrest.

EAST GRINSTEAD, a market town and urban district in the East Grinstead parliamentary division of East Sussex, England, 30 mi SSE of London by road. Pop. (1951) 10,845. Area 10.3 sq. mi. East Grinstead stands on a hill in an agricultural and wooded area overlooking the Medway valley and Ashdown forest to the southeast.

The urban district contains East Grinstead and the villages of Ashurst Wood and Kingscote, with agriculture and timber as its

chief industries. The buildings are of all periods from Tudor timber framed houses onward, the loveliest being Sackville college, built for an almshouse in 1608 or 1609 by Robert, 2nd earl of Dorset, and still used for that purpose. St Swithun's church, on the site of St Edmund's (960), stands on the hilltop and contains unusual fluted, concave pillars (late Perpendicular) and iron grave-slabs (from 1570); it was rebuilt after the collapse of the tower in 1735.

The Queen Victoria hospital became a centre for plastic surgery in 1939, after World War II a large wing was erected and equipped by the Canadian government, and in 1946 the U.S. surgical centre was opened.

Originally built as a clearing in the great forest of Andredswold (see WEALD, THE), Grenestede ("green place") was granted a charter in 1121. Lying directly between London and Pevensy, William I included it among the royal domains that went with Pevensy castle. It was discovered early and at the time of the Conqueror there was an iron mine there. Furnaces for the ironworks were fed from the surrounding forests until Henry VIII and Elizabeth I passed laws to preserve the trees. East Grinstead is an ancient borough which from 1307 until 1832 returned two members to parliament. In 1785 the king ordered the market to be held on Saturday instead of Sunday, and in 1516 a yearly fair was granted.

EAST HAM, a municipal, county and parliamentary borough of Essex, England, 6 mi E by N of London bridge. Pop. (1951) 120,873. Area 51.9 sq. mi. East Ham is bounded north by Wanstead, east by Ilford and Barking (the other side of the River Roding), south by the Thames and west by West Ham. The borough includes all or part of the districts of Wanstead Park, Manor Park, Forest Gate, Little Ilford, North Woolwich, Upton Park and East Ham itself. The northern part is mainly residential but along the Thames are many industries including the Bechtel works of the North Thames Gas board; there too are the larger part of the Royal Albert dock and the King George V dock. East Ham is intersected by the two main highways out of east London—the Romford and the Barking roads, a by-pass road cuts off the southern angle of the borough nearer the river on the way to Grays and Tilbury. Its growth during the end of the 19th and beginning of the 20th century was very rapid, and it now forms, geographically, part of the eastward extension of London.

A town development plan (1952) visualized a reduction in population to 110,000 within 20 years. Movement of population would be to Basildon New Town and other towns in Essex scheduled for expansion (e.g., Brentwood where the corporation was developing an estate).

East Ham belonged before the Conquest to Waltham abbey, whose possession of it was confirmed by Edward the Confessor. The parish church of St Mary Magdalen contains Norman work in the chancel and also a monument to Edmund Nevill, who claimed the earldom of Westmorland in the 16th century. William Stukeley, the antiquary (d. 1765), is buried in the churchyard. East Ham was incorporated in 1904, became a county borough in 1915 and has been represented by two members of parliament (for East Ham North and East Ham South) since 1918.

EASTHAMPTON, a town of Hampshire county, Massachusetts, U.S., in the Connecticut river valley, 17 mi NW of Springfield at an altitude of 169 ft., just west of Mount Tom. It is served by the Boston and Maine and the New York, New Haven and Hartford railways.

Pop. (1950) 10,694, in 1940 it was 10,316. Manufactures include rubber products, fireproof doors, clothing, furniture, advertising novelties, mercerized yarns and print goods. The manufacture of cloth-covered buttons (long a leading industry but discontinued) was built up by Samuel Williston (1795-1874) and his wife Emily Graves Williston, who first did the work by hand, then (1827) experimented with machinery, and in 1848 built a factory, and who in 1841 founded Williston academy, one of the oldest preparatory schools in New England. Easthampton was formed from parts of Northampton and Southampton in 1785 and was incorporated as a town in 1809.

EAST HAMPTON, a town of Suffolk county, N.Y., occupying the peninsula of Montauk at the east end of Long Island,

served by the Long Island railroad. The population in 1950 was 6,383. The scenery is varied and picturesque, and there are many summer homes and hotels. Montauk lighthouse, on Turtle hill, was first built in 1795. At Montauk point a large military camp was established after the Spanish American War. The principal villages are Sag Harbor (partly in the adjoining town), East Hampton and Amagansett. Most of the town was bought from the Indians in 1648 for about £30 by nine men from Massachusetts, and about 20 other families settled there in 1649, and until 1664, when all Long Island passed to the duke of York, the settlement was practically independent. In 1683, Gardiner's Island, settled in 1639, was made a part of East Hampton township. There are many tales of treasure buried by Captain Kidd on Gardner's Island and Montauk point.

Sag Harbor (settled in 1730 and incorporated in 1803) was held by the British after the battle of Long Island as a strategic naval and shipping point. It was an important whaling centre from 1785 until the embargo ruined the fisheries, and again from 1830 to 1870. "Home Sweet Home," the childhood home of John Howard Payne, is at East Hampton, a summer resort.

EAST INDIA COMPANY, an incorporated company for exploiting the trade with India and the Far East. In the 17th and 18th centuries East India companies were established by England, Holland, France, Denmark, Scotland, Spain, Austria and Sweden. The English, the most important of these, survived until it handed over its functions to the British government in 1858. It was founded at the end of the 16th century in order to compete with the Dutch merchants, who had obtained a practical monopoly of the trade with the Spice islands and had raised the price of pepper from 3s to 8s per lb. Queen Elizabeth incorporated it by royal charter, dated Dec. 31, 1600, under the title of "The Governor and Company of Merchants of London, trading into the East Indies." This charter conferred the sole right of trading with the East Indies, i.e., with all countries lying beyond the Cape of Good Hope or the Straits of Magellan, upon the company for a term of 15 years. Unauthorized interlopers were liable to forfeiture of ships and cargo. There were 125 shareholders in the original East India Company, with a capital of £72,000. The first governor was Sir Thomas Smythe. The early voyages of the company, from 1601 to 1612, reached as far as Japan (see Purchas' narratives), and are distinguished

Meanwhile friction was arising between the English and Dutch companies. The Dutch traders considered that they had prior rights in the Far East, and then ascendancy in the Indian archipelago was indeed firmly established on the basis of territorial dominion and authority. In 1613 they made advances to the English company with a suggestion for co-operation, but the offer was declined, and the next few years were fertile in disputes between the armed traders of both nations. In 1619 was ratified a "treaty of defence" to prevent disputes between the English and Dutch companies. When it was proclaimed in the East, hostilities solemnly ceased for the space of an hour, while the Dutch and English fleets, dressed out in all their flags and with yards manned, saluted each other, but the treaty ended in the smoke of that stately salutation, and perpetual and fruitless contentions between the Dutch and English companies went on just as before. In 1623 these disputes culminated in the "massacre of Amboyna," where the Dutch governor tortured and executed the English residents on a charge of conspiring to seize the fort. Great and lasting indignation was aroused in England, but it was not until the time of Cromwell that some pecuniary reparation was exacted for the heirs of the victims. The immediate result was that the English company tacitly admitted the Dutch claims to a monopoly of the trade in the Far East and confined their operations to India and adjoining countries.

The need for good ships for the East Indian trade had led the company in 1609 to construct their dockyard at Deptford, from which, as Monson observes, dates "the increase of great ships in England." Down to the middle of the 18th century, the famous "East Indiamen" held unquestioned pre-eminence among the merchant vessels of the world. Throughout the 17th century they had to be prepared at any moment to fight not merely Malay pirates, but the armed trading vessels of their Dutch, French, and Portuguese rivals. Many such battles, usually with successful results, are recorded in the company's history.

It was not until it had been in existence for more than a century that the English East India Company obtained a practical monopoly of the Indian trade. In 1635, a year after the Great Mogul had granted it the liberty of trading throughout Bengal, Charles I. issued a licence to Courten's rival association, known as "the Assada merchants," on the ground that the company had neglected English interests. The practical methods of their rivals disgraced the company with the Mogul officials, and a *modus vivendi* was only reached in 1649. In 1657 Cromwell renewed the charter of 1609, providing that the Indian trade should be in the hands of a single joint stock company. The new company thus formed bought up the factories, forts, and privileges of the old one. It was further consolidated by the fostering care of Charles II., who granted it five important charters. From a simple trading company, it grew under his reign into a great chartered company—to use the modern term—with the right to acquire territory, coin money, command fortresses and troops, form alliances, make war and peace, and exercise both civil and criminal jurisdiction. It is accordingly in 1680, when the three presidencies of Bengal, Madras, and Bombay had lately been established, that the ruling career of the East India Company begins. From this moment the history of the transactions of the East India Company becomes the history of British India (see *India History*). Here we shall only trace the later changes in the constitution of the ruling body itself.

The great prosperity of the company under the Restoration and the immense profits of the Indian trade attracted a number of private traders, both outside merchants and dismissed or retired servants of the company, who came to be known as "interlopers." In 1683 the case of Thomas Sandys, an interloper, raised the whole question of the royal prerogative to create a monopoly of the Indian trade. The case was tried by Judge Jeffreys, who upheld the royal prerogative, but in spite of his decision the custom of interloping continued and laid the foundation of many great fortunes. By 1691 the interlopers had formed themselves into a new society, meeting at Dowgate, and rivaling the old company, the case was carried before the House of Commons, which declared in 1694 that "all the subjects of England have

BY COURTESY OF MESSRS. COLMAGNI, SALL AND COMPANY

EAST INDIA HOUSE THE LAST HOME OF THE EAST INDIA COMPANY

This building, on the site of the old house in 1726, was sold in 1859

as the "separate voyages," because the subscribers individually bore the cost of each voyage and reaped the whole profits, which seldom fell below 100%. After 1612 the voyages were conducted on the joint stock system for the benefit of the company as a whole. In 1610-11 Captain Hippon planted the first English factories on the mainland of India, at Masulipatam and at Patnapur in the Bay of Bengal. In 1609 James I. renewed the company's charter "for ever," though with a proviso that it might be revoked on three years' notice if the trade should not prove profitable to the realm.

equal right to trade to the East Indies unless prohibited by act of parliament." This decision led up to the act of 1698, which set up a new East India Company in consideration of a loan of two million to the state. The old company subscribed £315,000 and became the dominant factor in the new body, while at the same time it retained its charter for three years, its factories, forts, and assured position in India. The rivalry between the two companies continued both in England and in India, until they were finally amalgamated by a tripartite indenture between the companies and Queen Anne (1702), which was ratified under the Godolphin ward (1708). Under this award the company was to lend the nation £3,200,000, and its exclusive privileges were to cease at three years' notice after this amount had been repaid. But by this time the need for permanence in the Indian establishment began to be felt, while parliament would not relinquish its privilege of "milking" the company from time to time. In 1712 an act was passed continuing the privileges of the company even after their fund should be redeemed, in 1730 the charter was prolonged until 1766, and in 1742 the term was extended until 1783 in return for the loan of a million. This million was required for the war with France, which extended to India and involved the English and French companies there in long-drawn hostilities, in which Dupleix and Clive became prominent.

So long as the company's chief business was that of trade, it was left to manage its own affairs. The original charter of Elizabeth had placed its control in the hands of a governor and a committee of 24, the chairman and court of directors in London exercising unchecked control over their servants in India. But after Clive's brilliant victory at Plassey (1757) had made the company a ruling power in India, it was considered essential that the British government should have some control over the territories thus acquired. Lord North's Regulating act (1773) raised the governor of Bengal—Warren Hastings—to the rank of governor-general, and provided that his nomination, though made by a court of directors, should in future be subject to the approval of the crown, in conjunction with a council of four, he was entrusted with the power of peace and war, a supreme court of judicature was established, to which the judges were appointed by the crown, and legislative power was conferred on the governor-general and his council. In 1784 Pitt's India bill created a board of control, as a department of the English government, to exercise political, military, and financial superintendence over the British possessions in India. This bill first authorized the historic phrase "governor-general in council." From this date the direction of Indian policy passed definitely from the company to the governor-general in India and the ministry in London. In 1813 Lord Liverpool passed a bill which gave the board of control authority over the company's commercial transactions and abolished its monopoly of Indian trade. The monopoly of the valuable trade with China, chiefly in tea, was ended by Earl Grey's act of 1833. Its property was then secured on the Indian possessions, and its annual dividends of ten guineas per £100 stock were made a charge upon the Indian revenue. Henceforward the East India Company ceased to be a trading concern and exercised only administrative functions. Such a position could not, in the nature of things, be permanent, and the Indian Mutiny was followed by the entire transference of Indian administration to the crown on Aug. 2, 1858.

EASTLAKE, SIR CHARLES LOCK (1793-1865), English painter, art historian and museum director, was born at Plymouth, Devon, on Nov. 17, 1793. He went to Plympton Grammar school (concurrently learning drawing from Samuel Prout, q.v.) and briefly to the Chateaufort, London. But in 1809 a resolve, "unalterably fixed," to become a painter of "history" (i.e., of sculpture, allegory, antiquity or literature as opposed to everyday life or portraits) brought him as pupil to B. R. Haydon (q.v.) and to the Royal Academy schools. By 1812 he had finished his first commission, the "Raising of Jureus's Daughter," and in 1815 came the famous "Buonaparte on Board the Bellerophon," the proceeds of whose sale took him to Rome in 1816. There till 1830 he worked in a congenial society that included Sir Thomas Lawrence, J. M. W. Turner and William Lill, S. W. Humphrey Davy and Thomas Moore. Rome and the Campagna deflected him for a while from "history" to landscape, his skill in which appears in his later "banditti" pictures, now also were begun his copious notebooks, many of which are preserved in the National gallery, London. He was elected A.R.A. in 1817 and R.A. in 1830, in 1850 he succeeded Sir Martin Archer Shee as president of the Royal Academy and was knighted.

With his appointment in 1855 to the new directorship of the National gallery—whose keeper he was from 1843 till his resignation in 1847 in face of unjust criticisms—the artist was finally displaced by the writer, administrator and arbiter of national and court taste and Eastlake is best remembered for his part in raising the gallery to European status and for his books *Materials for a History of Oil Painting* (1847) and *Contributions to the Literature of the Fine Arts* (2 series, 1848-1870). He died at Pisa, Dec. 24, 1865.

In 1849 he had married Elizabeth Rigby, author of *Letters from the Baltic* (1841). Lady Eastlake (1809-93) was also a considerable diarist and translator of G. F. Waagen's *Treasures of Art in Great Britain* (1845-57). Their nephew CHARLES LOCK EASTLAKE (1835-1906) was keeper of the National gallery, 1878-98, and a writer on painting and industrial art.

BIBLIOGRAPHY—W. Cosmo Monkhouse, *Pictures by Sir Charles Eastlake* (London 1875), Lady Eastlake, *Memoir of Sir C. L. Eastlake*, in his *Contributions*, 2nd series (London, 1870), includes catalogue of his paintings, C. Eastlake Smith (ed.), *Journals and Correspondence of Lady Eastlake*, 2 vol. (London, 1895).

EASTLEIGH, a municipal borough in the Winchester parliamentary division of Hampshire, Eng., 4 mi. NNE of Southampton. Area is 9.9 sq. mi. Population in 1951 census was 30,557. Incorporated in 1936, it includes the districts of Chandler's Ford, Albury, Bishopstoke and parts of North Stoneham, Otterbourne, Fair Oak and Stoke Park. Lying in well-wooded country, it is in part residential and in part industrial, the chief industry being the works of the British Railways (Southern region).

The church of St. Nicolas at North Stoneham is one of the earliest ecclesiastical foundations in England, though it shows no trace of the old Saxon building. It contains the memorial to Sir Thomas Flemyngh, who sentenced Guy Fawkes to death, and for centuries a celebration took place every Nov. 5.

EAST LIVERPOOL, a city of Columbiana county, O, U.S., 40 mi. W by N of Pittsburgh, on the Ohio river, opposite Newell and Chester, W. Va. It is on federal highway 30 and is served by the Pennsylvania railroad and motorbuses and river steamboats. The population of East Liverpool was 24,217 in 1950, it was 23,555 in 1940 and 23,349 in 1930 by the federal census. It has large machine works, a drawn steel plant and several small machine plants, electric porcelain plants and other industries. There are pottery plants in this city and in Chester and Newell, the latter two cities are served with two large passenger and traffic bridges. The potteries employ 6,500 wage earners. The city is built on sloping ground, rising from the river bank, in the midst of beautiful scenery.

In 1798 Thomas Fawcett settled there, and in 1802 he laid out a town, which he named St. Clair but others persisted in calling Fawcettstown. The name Liverpool was adopted in 1816, and in 1834, when the town was incorporated, East was prefixed, to distinguish it from another settlement in the state. The dominating industry dates from 1839, when James Bennett, an English potter, reached the small town, and judged that the clays in the surrounding hills would make an excellent-quality yellow ware. The manufacture of white ware began in 1872, of semivitreous china about 1890, while the production of porcelain electrical fixtures

and supplies developed in the 20th century. Local clays are still used for yellow ware by one plant, but with this exception all the raw materials needed by the potteries come from a distance: the clays from Florida, North Carolina, Kentucky and England, other minerals from distant states, Canada and Italy. Labour-saving machinery displaced the potter's wheel in East Liverpool at an early date.

EAST LONDON, a city of the Union of South Africa, 33° 3' S, 27° 55' E. Its population, including that of the suburbs, such as Cambridge, 4 mi away, is (1953 est.) 91,707 including 43,780 Europeans, 40,457 natives, 5,877 "coloured" (i.e., mixed) and 1,593 Asiatics. The town is situated at the mouth of the Buffalo river, 566 mi by sea from Cape Town, 253 mi from Durban and 665 mi by rail from Johannesburg. The first settlement was a military post on the west bank of the river. It was established to serve as a base port in 1846 during the border wars and was then known as Port Rex. In 1848 it was renamed East London and in 1871 it was created a municipality, it was incorporated in 1880 and made a city in 1897. When the railway was constructed on the opposite bank in 1874, the business and commercial centre moved across the river. Buffalo bridge, a combined road and railway bridge, was completed in 1935. The main town, built on a plateau 150 to 200 ft high, is laid out in broad, straight streets, the principal ones being Oxford, Cambridge and Buffalo streets crossed by Fleet street.

The climate is influenced by the warm Mozambique current off the coast. The mean minimum temperature is 57° F and relative humidity about 87%. The mean annual rainfall is about 30 in, but the building of the Laing dam has ensured the water supply in times of drought.

Because of its equable climate, its facilities for surf bathing and the attraction of its river, East London is one of the principal holiday resorts of the South African coast. Along the shore to the northeast of the river a fine-weather esplanade was made, there are two parks, Queens park (about 60 ac) and James Pearce park (about 30 ac). There are also a zoo, a museum and an aquarium (both opened in 1931) and an art gallery.

The silting up of the river delayed the development of the port, but in 1886 a suction dredger was put to work. Extensive harbour improvements enabled the port to accommodate the larger boats serving South Africa. In 1947 the Princess Elizabeth graving dock was opened. East London ranks as the fourth port of South Africa and is its only river port. It takes a large part of the trade of the eastern part of Cape Province of the Transkei and native territories, of Basutoland and part of the Orange Free State. There is a railway line to Witwatersrand through the Orange Free State gold fields. Important exports are wool, pineapples, citrus fruits and hides; timber is the chief import. During 1950-51 853,020 harbour tons of traffic were handled. Wool is the city's main industry, but other important ones include sweets, furniture, textiles and paints and varnishes, some fishing is done.

Seven miles from the market square, at Collondale, West Bank, is the airport.

EAST LOTHIAN (or **HADDINGTONSHIRE**), a southeastern county of Scotland, bounded north by the Firth of Forth, northeast by the North sea, east and south by Berwickshire and southwest and west by Midlothian. Land area is 267.1 sq mi. The sea-

fronted part of the Saxon kingdom of Northumbria until 1018, when it was joined to Scotland by Malcolm II. It was comparatively prosperous till the wars of Bruce and Balaol, but from that period down to the union of the kingdoms it suffered from its nearness to the Border and from civil strife. The last battle fought in the county was that of Dunbar (1650) and Prestonpans (1745). Haddington (qv) is supposed to be the birthplace of John Knox (qv).

Agriculture and Industries—East Lothian has for centuries been famous for the fertility of its soil and the excellence of its agriculture. The Lammermuirs are given over largely to sheep, though the lower slopes are cultivated. In the centre of the shire occurs a belt of tenacious boulder clay on a tully subsoil not adapted for agriculture. The coast is sandy, but farther inland the rich loam is very fertile, and barley, wheat, hay, turnips, swedes and potatoes are grown extensively. The red soil about Dunbar yields a potato—the "Dunbar red"—highly esteemed in the markets. There are large and small holdings and much improved pasture. Some fishing is carried on at Dunbar, North Berwick and Port Seton. Fire clay is worked in association with coal mining, and limestone is quarried at Oxwellmans and East Saltoun. Industries include the manufacture of agricultural implements, bricks, woollens and felt, besides brewing and distilling, boat building and sawmilling. Only a limited part of the Carboniferous limestone area includes the coal measures, but coal is extensively worked at Tranent, Ormiston and near Prestonpans, the coal field having an area of about 10 sq mi.

Population and Government—The population in 1951 was 52,740, of whom 10 spoke Gaelic. The chief towns (pop. 1951) are Dunbar (4,115), Haddington, the county town (4,497), and North Berwick (4,001), the three royal burghs, and Prestonpans (1,907), Tranent (5,633), Cockenzie and Port Seton (3,180) and East Linton (990), all small burghs, of which there are seven. There are five county districts. The shire, which returns one member of parliament with Berwickshire, forms part of the shire of the Lothians and Peebles, and a sheriff substitute sits at Haddington.

EASTMAN, GEORGE (1854-1932), U.S. inventor, manufacturer and philanthropist, was born at Waterville, N.Y., on July 12, 1854. He was educated at Rochester and became interested in photography. In 1880 he began to manufacture dry plates and four years later produced the first practicable roll film. In 1888 he invented the "Kodak." He devoted the greater part of his fortune to the advancement of education, and had given by 1925 a total of more than \$8,000,000 for such purposes. Of this sum the University of Rochester received more than \$2,500,000, including about \$5,500,000 for the medical school and \$6,500,000 for the foundation and endowment of the Eastman school of music. He gave also \$15,500,000 to the Massachusetts Institute of Technology and about \$2,000,000 to the Hampton and Tuskegee institutes. He died March 14, 1932. (See PHOTOGRAPHY.)

EAST MOLINE, a city of Rock Island county, Ill., U.S., on the Mississippi river, adjoining Moline. It is served by the Burlington, the Chicago, Milwaukee, St. Paul and Pacific, the Rock Island and the Davenport, Rock Island and Northwestern railways. Pop. (1950) 13,913, (1940) 12,359 by federal census. It has important manufactures, similar to those of the neighbouring cities, including especially ploughs, scales, laundry machinery, harvesting machinery, steel playthings, pressed steel and voltage regulators. The city was incorporated in 1897.

EASTON, a city of eastern Pennsylvania, U.S., on the Delaware river, at the mouth of the Lehigh and Bushkill rivers, opposite Phillipsburg, N.J., 60 mi N of Philadelphia and 70 mi W of New York city, the county seat of Northampton county. It is on federal highways 22 and 611, is served by the Jersey Central, the Lehigh Valley, the Lehigh and Hudson River and (through Phillipsburg) the Lackawanna and the Pennsylvania railways, and is at the junction of the Delaware and the Lehigh canals. The population was 35,632 in 1950, 33,589 in 1940, and 34,468 in 1930 by the federal census. The city is beautifully situated on rolling ground, commanding fine views of hills and rivers. The total bank resources are approximately \$85,000,000 and building and loan resources \$5,000,000. On a hill overlooking the city is Lafayette college, an institution for men, opened in 1832, which has an enrolment of about 2,000. It was named after the marquis de la Fayette, who was on tour through the United States when the movement to establish the college was launched in 1824. Easton is the commercial centre of a region rich in mineral and agricultural resources. Abundant hydroelectric power is available, and the city has important and varied manufactures, with a total industrial pay roll of more than \$40,000,000.

History

—Of the early Celtic inhabitants, traces are found in a few place names and circular camps (in the parishes of Garvald and Whittingehame) and hill forts (in the parish of Bolton). Excavations at Traprain Law, carried on after 1914, gave evidence that this hill, a natural stronghold strengthened by earthworks, was in occupation nearly continuously from the Bronze Age to the beginning of the 5th century A.D. Most of the objects found are Celtic, but there was also a hoard of Roman silver plate of the 4th century, weighing more than 770 oz. and believed to have been pillaged from Gaul by Saxon pirates after the Roman occupation, of which few traces remain, the district

usually. Among the principal products are steel, cement, silk, hosiery, paper cups, flour and feed, rope and twine, pumps, machinery of many kinds, etc. Easton was settled by Thomas and John Penn, brothers of William Penn and was named after the family of Thomas Penn's wife. The land was acquired in 1757 from the Indians, who had had a trading post at that point, and several important treaties were negotiated with them there between 1756 and 1762, during the French and Indian War. The First Reformed church, built in 1776 and still standing, was used as a hospital during the Revolution. The bell rung to summon the people to the official reading of the Declaration of Independence on July 8, 1776, still hangs in the belfry of the courthouse, and the flag unfurled on that occasion is in the public library. The city of Easton was incorporated as a borough in 1789, as a city in 1887.

EAST ORANGE, a city of Essex county, N. J., U. S., 11 mi. W. of New York city, adjoining New York. It is served by the Erie and the Lackawanna railways, and by interurban trolley and motor coach lines. The population was 79,340 in 1950, 68,945 in 1940 and 68,020 in 1930 by federal census. East Orange and the adjoining municipalities of Orange, West Orange, South Orange and Maplewood (together known as "the Oranges") form a suburban community, with a population of 186,413 in 1950.

In East Orange is Upsala college (Lutheran, established 1893), and in South Orange, Seton Hall college (Roman Catholic, 1856). Its manufacturing industries are concentrated largely in the section called Amperre, and the principal products are sewer pipe, motors, dynamos, valves and pipe fittings and waterworks supplies. In 1865 the township of East Orange was separated from the township of Orange, which had been set off from Newark in 1806, and in 1899 the city was incorporated.

EAST PALESTINE, a city of Columbiana county, O., U. S., on the Pennsylvania railroad, near the eastern boundary of the state, 20 mi. S. by E. of Youngstown. Pop. (1950) 5,195, in 1940 it was 5,123 by the federal census. Coal, fire clay and oil shales abound, it has manufactures of building tile, furniture, milling machinery, kitchen cabinets, chinaware, electrical refractories, etc.

EAST PITTSBURGH, a borough of Allegheny county, Pa., U. S., on the Monongahela river, 12 mi. S. E. of Pittsburgh. It is served directly by the Pennsylvania railroad and, through the Union railroad, by the Bessemer and Lake Erie, the Baltimore and Ohio, the Pittsburgh and Lake Erie and the Pittsburgh and West Virginia railways. Pop. (1950) 5,259, (1940) 6,079. The principal manufactures are electrical products. The borough was settled about 1871 and incorporated in 1895.

EAST POINT, city of Fulton county, Ga., U. S., 4 mi. from the southern boundary of Atlanta, served by the Atlanta and West Point and the Central of Georgia railways. Pop. 21,080 in 1950 and 12,403 in 1940 by the federal census. It is a residential and industrial suburb, with a land area of 7.5 sq. mi.

EASTPORT, a city of Washington county, Me., occupying Moose Island, in Passamaquoddy bay, a port of entry and the most easterly city of the United States. It is served by the Maine Central railroad and by steamer lines and ferries. The population in 1950 was 3,123. It has a large sardine canning industry and is the centre for the manufacture of pearl essence from fish scales. Large reduction plants utilize the fish waste to manufacture fish meal and allied products. Eastport is the site of the immense hydroelectric tidal power development, having the highest rise and fall of tides in the United States. The largest whirlpool in the western hemisphere forms off its eastern shore. Eastport was settled by fishermen in 1782, became a port of entry in 1790, was incorporated as a town in 1798 and as a city in 1893. Under the Embargo acts of 1807 and 1808 it was a notorious place for smuggling. During the War of 1812 it was taken by the British (July 12, 1814), and after the close of the war was held under martial law until July 1818, when it was surrendered to the U. S. in accordance with the provisions of the treaty of Ghent.

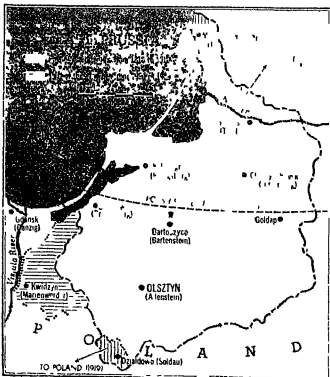

EAST PROVIDENCE, a town of Providence county, R. I., U. S., on the east side of the Seekonk and Providence rivers, opposite Providence. It is served by the New York and Haven and Hartford railroad. Pop. (1950) 35,871. There are four sections of the town. Watchemoket, the largest, Phillipsdale, contain-

ing most of the manufacturing, Rumford, which has a large chemical works, and River side with attractive summer resorts. Oysters are shipped, other products include petroleum, wire and cable and jewellery. Roger Williams established himself there in the spring of 1636 but left when he learned that he was within the jurisdiction of Plymouth colony. Permanent settlement dates from 1644. In 1861 it was decided that the territory belonged to Rhode Island. The town was incorporated in 1862.

EAST PRUSSIA (OSTPREUSSEN). A former German province bounded between World Wars I and II, north by the Baltic sea, east by Lithuania and south and west by Poland and the Free City of Danzig. The name "Prussia" is linguistically of Baltic origin, its ancient inhabitants, exterminated by the Knights of the Teutonic Order, called themselves *Prusai*. When the Knights conquered the Polish province of Pomerania in 1308 the name "Prussia" was extended westward covering the whole territory administered by the Teutonic Order. In 1466 Poland recovered Pomerania (and the region of Warmia, or Ermland, in the Old Prussia), and between that date and 1701 (when the elector of Brandenburg became "king in Prussia") the country held directly by the crown of Poland was called Royal Prussia to distinguish it from the land retained by the knights in Poland's vassals, which became a security duchy (Ducal Prussia) in 1525 and was freed from Polish suzerainty by the treaty of Wehlau (1607). From 1815 the name "East Prussia" was given to the easternmost province of the kingdom of Prussia. The boundaries of this province remained unchanged until World War I. Its area was then 14,284 sq. mi. and its population in 1910 amounted to 2,061,175.

As a result of the treaty of Versailles (1919) the Memel (Klaipeda) territory was taken from Germany (in 1924 it was incorporated into Lithuania), the district of Soldau (Działdowo) was given to Poland, while the regency of Marienwerder (Kwidzyn), formerly part of the province of West Prussia, joined East Prussia, now territorially separated from the rest of Germany. The new area of East Prussia (1920-19) was 14,304 sq. mi. and its population (according to the census of 1924) amounted to 2,756,349, of which total 83.8% were Lutheran and 15% Roman Catholic.

After World War II East Prussia was partitioned between Poland (the southern part) and the U. S. S. R. (the northern part), the frontier running north of Goldap, Bartenstein (Bartoszyce) and Braunsberg (Braniewo). The northern part was incorporated into the Russian federation and colonized by Russians. Königsberg became Kaliningrad, Insterburg, Chernyakhovsk, and Tilsit, Sovetsk. In the southern part about 400,000 indigenous Poles (whom the Germans had called *Masuren*) remained, and immigrants from pre-1939 Poland replaced the Germans, who either had fled in 1944 or were evacuated after 1945.

EAST SAINT LOUIS, a city of St. Clair county, Ill., U.S., on the Mississippi river, opposite St. Louis, with which it is connected by three great steel bridges, one of the great railway centres of the country and an important manufacturing city. It is the focus of 31 railroads from the east, north and south, including the Alton and Southern, the Baltimore & Ohio, the Illinois Central, the Illinois Terminal, the Burlington, the Chicago & Eastern Illinois, the New York Central, the Litchfield and Madison, the Louisville & Nashville, the Missouri Pacific, the Gulf Mobile and Ohio, the Frisco, the Nickel Plate, the Pennsylvania, the St. Louis Southwestern, the Southern, the Terminal and the Wabash, is on federal highways 40, 50, 66 and 67, and is served by many local and transcontinental bus lines. The population in 1930 was 82,295 and was 75,609 in 1940 according to the federal census.

The city occupies 13.4 sq mi of the Mississippi bottom land, not much above the high-water mark of the river, but adequately protected by strong levees.

The assessed valuation of property in 1950 was \$160,000,000. Coal is mined at its doors.

Meat packing houses employ approximately 5,000 men. Other leading manufactures are alumina, chemicals, glass bottles, paint pigments, railway equipment, roofing, brick, tile, pipe line valves and petroleum products. The stockyards are the second largest concentration point of livestock in the United States. Races are held regularly in the spring and fall.

East Saint Louis was laid out about 1808, and was chartered as a city in 1865. It grew most rapidly between 1900 and 1910, when the population almost doubled.

There is a famous prehistoric mound (Monk's mound) near the city. The village of Cahokia, at the southern edge of the city, was one of the earliest French settlements in the Mississippi valley.

EAST STROUDSBURG, a borough of Monroe county, Pa., U.S., adjoining Stroudsburg (qv) and 20 mi N of Easton, surrounded by the beautiful scenery of the Kittatinny range and the Pocono mountains.

It is on federal highway 611 and is served by the Lackawanna and the Pennsylvania railways. The population was 7,274 in 1950 and was 6,404 in 1940 and 6,099 in 1930 by the federal census. It is a resort centre.

The borough has sundry manufacturing industries, has a progressive education system and is the seat of a state teachers' college (opened 1893).

EATON, DORMAN BRIDGMAN (1823-1899), American lawyer, was born at Hardwick, Vt., June 27, 1823. He graduated at the University of Vermont in 1848 and at the Harvard law school in 1850, and in the same year was admitted to the bar in New York city. There he became associated in practice with William Kent, the son of the great chancellor. He was conspicuous in the fight against William Marcy (Boss) Tweed and his followers, by one of whom he was assaulted, he required a long period of rest, and went to Europe, where he studied the workings of the civil service in various countries. From 1873 to 1875 he was a member of the first United States civil service commission. In 1877, at the request of Pres. Rutherford B. Hayes, he made a careful study of the British civil service, and three years later published *Civil Service in Great Britain*. He drafted the Pendleton Civil Service act of 1883, and later became a member of the new commission established by it. He resigned in 1885, but was almost immediately reappointed by Pres. Grover Cleveland, and served till 1886, editing the third and fourth *Reports of the commission*. He was an organizer (1878) of the first society for the furtherance of civil service reform in New York, of the National Civil Service Reform association, and of the national conference of the Unitarian Church (1865). He died in New York city, Dec. 23, 1899. Among his publications were: *Should Judges Be Elected?* (1873), *The Spoils System and Civil Service Reform* (1882), *Problems of Police Legislation* (1895) and *The Government of Municipalities* (1899).

See the privately printed memorial volume, *Dorman B. Eaton, 1823-99* (1900).

EATON, MARGARET O'NEILL (1796-1879), better known as Fanny O'Neill, was the daughter of the keeper of a popular Washington tavern, and was noted for her beauty, wit and vivacity. About 1823, she married a purser in the United States navy, John B. Timberlake, who committed suicide while on service in the Mediterranean in 1828. In the following year she married John Henry Eaton (1790-1850), a Tennessee politician, at the time a member of the United States senate. Senator Eaton was a close personal friend of Pres. Andrew Jackson who in 1829 appointed him secretary of war. This sudden elevation of Mrs. Eaton into the cabinet social circle was resented by the wives of several of Jackson's secretaries, and charges were made against her of improper conduct with Eaton previous to her marriage to him. The refusal of the wives of the cabinet members to recognize the wife of his friend angered President Jackson, and he tried in vain to coerce them. Eventually, and partly for this reason, he almost completely reorganized his cabinet. The effect of the incident on the political fortunes of the vice president, John C. Calhoun, whose wife was one of the recalcitrants, was perhaps most important. Partly on this account, Jackson's favour was transferred from Calhoun to Martin Van Buren, the secretary of state, who had taken Jackson's side in the quarrel and had shown marked attention to Mrs. Eaton, and whose subsequent elevation to the vice-presidency and presidency through Jackson's favour is no doubt partly attributable to this incident. In 1836 Mrs. Eaton accompanied her husband to Spain, where he was United States minister in 1836-40. After the death of her husband she married a young Italian dancing master, Antonio Buchignani, but soon obtained a divorce from him. She died in Washington on Nov. 8, 1879.

See James Parton's *Life of Andrew Jackson* (1860).

EATON, THEOPHILUS (c. 1590-1658), English colonial governor in America, born at Stony Stratford, Buckinghamshire, about 1590, settled in London, where he joined the Puritan congregation of the Rev. John Davenport. The pressure upon the Puritans increasing, Eaton, who had been one of the original patentees of the Massachusetts Bay Colony in 1629, determined to use his influence and fortune to establish an independent colony of which his pastor should be the head. He emigrated with Davenport to Massachusetts, and in the following year (March 1638) he and Davenport founded New Haven. In Oct. 1639 a form of government was adopted, based on the Mosaic law, and Eaton was elected governor, a post which he continued to hold, first over New Haven alone, and after 1643 over the New Haven colony or jurisdiction, until his death at New Haven, Jan. 7, 1658. He was prominent in the affairs of the New England confederation, of which he was one of the founders (1643). In 1655 he and Davenport drew up the code of laws, popularly known as the "Connecticut blue laws".

A sketch of his life appears in Cotton Mather's *Magnalia* (London, 1702), see also J. B. Moore's "Memoir of Theophilus Eaton" in the *Collections of the New York Historical Society*, second series, vol. II (New York, 1849).

EATON, WILLIAM (1764-1811), American soldier, was born in Woodstock, Conn., on Feb. 23, 1764. He was a school teacher for several years, graduated at Dartmouth college in 1790, and in 1792 entered the army as a captain, later serving against the Indians in Ohio and Georgia. In 1797 he was appointed consul to Tunis, where he arrived in Feb. 1799. In March 1799, with the consuls to Tripoli and Algiers, he negotiated alterations in the treaty of 1797 with Tunis. He rendered great service to Danish merchantmen by buying on credit several Danish prizes in Tunis and turning them over to their original owners for the redemption of his notes. In 1803 he quarrelled with the bey, was ordered from the country and returned to the United States. In 1804 he returned to the Mediterranean as U.S. naval agent to the Barbary States with James Barron's fleet. On Feb. 23, 1805, he agreed with Ahmet that the United States should undertake to re-establish him in Tripoli, that the expenses of the expedition should be repaid to the United States by Ahmet and that Eaton should be general and commander in chief of the land forces in Ahmet's campaign. In making the arrangement Eaton far

exceeded his authority. On March 8 he started for Derna across the Libyan desert from the Arab's Tower 40 mi west of ALEXANDRIA, with a force of about 500 men, including a few Americans, about 40 Greeks and some Arab cavalry. In the march of nearly 600 mi the camel drivers and the Arab chiefs repeatedly mutinied, and Ahmet Pasha once put himself at the head of the Arabs and ordered them to attack Eaton. Ahmet more than once wished to give up the expedition. But on April 27, with the assistance of three bombarding cruisers, Eaton captured Derna—an exploit commemorated by Whittier's poem *Deine*. In May and again in June he successfully withstood the attacks of Tripolitan forces sent to dislodge him. On June 12 he abandoned the town upon orders from Commodore Rodgers, for peace had already been made (June 4) with Yussuf, the *de facto* pasha of Tripoli. Eaton returned to the United States and received a grant of 10,000 ac in Maine from the Massachusetts legislature. According to a deposition which he made in 1807 he was approached by Aaron Burr (q.v.), who attempted to enlist him in his "conspiracy." As he received from the government, soon after making this deposition, about \$10,000 to liquidate claims for his expense in Tripoli, which he had long pressed in vain, his good faith had been doubted. At Burr's trial at Richmond in 1807 Eaton was one of the witnesses but his testimony was unimportant. He died on June 1, 1811, in Brimfield, Mass.

See the anonymously published *Life of the Late Gen. William Eaton* (Brookfield, Mass., 1811) by Charles Prentiss, C. C. Felton, "Life of William Eaton" in Sparks's *Library of American Biography*, vol. 15 (Boston, 1838), Gardner W. Allen's *Our Navy and the Barbary Corsairs* (Boston, 1905), and William Abbott, "A Forgotten Hero, William Eaton," *Mag of Hist.*, vol. vi, pp. 1-11 (1907). See also E. A. Powell, *Gentlemen Rovers* (1913), and M. Minnigerode, *Lives and Times* (1914).

EATON, WYATT (1849-1896), American portrait and figure painter, was born at Philipsburg, Canada, on May 6, 1849. He was a pupil of the schools of the National Academy of Design, New York, and in 1872 went to Paris, where he studied in the Ecole des Beaux Arts under J. L. Gurome. He made the acquaintance of J. F. Millet at Barbizon, and was also influenced by his friend Jules Bastien-Leprieux. After his return to the United States in 1876 he became a teacher in Cooper Institute and opened a studio in New York city. He was one of the organizers (and the first secretary) of the Society of American Artists.

Among his portraits are those of William Cullen Bryant and Timothy Cole, the wood engraver ("The Man with the Violin"). Eaton died at Newport, R. I., on June 7, 1896.

EAU CLAIRE, a city of northwestern Wisconsin, U. S., 84 mi E of Saint Paul, on the Chippewa river at the mouth of the Eau Claire, the county seat of Eau Claire county. It is on federal highways 10, 12 and 53, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific and the Soo line railways.

The population was 36,038 in 1930 and 30,745 in 1940, by federal census. There is abundant water power, and the city has large and diversified manufacturing enterprises. It is the principal tooling center for the prosperous Chippewa valley. The city adopted and placed in effect the council manager form of government in 1939. It is one seat of a state teachers college, a county tuberculosis hospital and a county hospital for the insane. There are six municipal organizations and an auditorium seating 2,000. A state fish hatchery, several good fishing in the vicinity.

Eau Claire was settled about 1817, chartered as a city in 1873 and grew rapidly with the development of the northwestern lumber trade in the decade 1870-80.

A serious strike in 1881 necessitated the calling out of the state militia.

EAU DE COLOGNE, a perfume so named from the city of Cologne, where its manufacture was first established by its Italian, Johann (or Giovanni) Maria Farina (1685-1766), who settled at Cologne in 1709. The perfume gained a high reputation by 1766, and Farina associated himself with his nephew, to whose grandson the secret was ultimately imparted, the original perfume is still manufactured by members of this family under the name

of the founder. The manufacture is, however, carried on at Cologne, and also in Italy, by other firms bearing the name Farina, and the scent has become part of the regular output of perfumers. The discovery has also been ascribed to a Paul de Femins, who is supposed to have brought his recipe from Milan to Cologne, of which he became a citizen in 1660, and sold the perfume under the name *Eau admirable*, leaving the secret at his death to his nephew Johann Maria Farina. It was prepared from an alcoholic infusion of certain flowers, pot herbs, drugs and spices, distilling and then adding definite quantities of several vegetable essences. The purity and thorough blending of the ingredients are of the greatest importance. The original perfume is simulated and even excelled by artificial preparations. The oils of lemon, bergamot and orange are employed, together with the oils of neroli and rosemary in the better class. The common practice consists in dissolving the oils, in certain definite proportions based on experience, in pure alcohol and distilling, the distillate being diluted by rose water.

EAU DE VIE *see* BRANDY

EAUX-BONNES, a watering place of southwestern France, in the department of Basses-Pyrenees, $\frac{3}{4}$ mi S. E. of the small town of Laruns, the latter being 24 mi S. of Pau by rail. Population (1946) town, 253, commune, 570, (1952 est.) commune 500. Eaux Bonnes stands at a height of 2,460 ft. at the mouth of a fine gorge, at the confluence of two torrents, the Valentin and the Soudre. Its sulphurous and silice mineral waters (famous from the 14th century) are beneficial in affections of the throat and lungs. They vary between 50° and 90° C in temperature and are used for drinking and bathing. There are two thermal establishments, a casino and fine promenades.

The watering place of LES EAUX CHAUDES is 5 mi by road southwest of Les Eaux-Bonnes, in a wild gorge on the Gave d'Ossau. Population (1952 est.) 392. The springs are sulphurous, varying in temperature from 52° to 97° C, and are used in cases of rheumatism and for lung and skin complaints. There is fine mountain scenery in the neighbourhood of both places. The valley of Ossau is one of the most beautiful in the Pyrenees. Before the Revolution it comprised a community which, though dependent on Bearn, had its own legal organization, manners and costumes.

EAVES, in architecture, the projecting edge of a sloping roof, which overhangs the face of the wall so as to throw off the water.

EAVESDROP or **EAVESDROPPING**, that width of ground around a house or building which receives the rain water dropping from the eaves. By an ancient Saxon law, a landowner was forbidden to erect any building at less than two feet from the boundary of his land, and was thus prevented from injuring his neighbour's house or property by the dripping of water from his eaves. The law of eavesdropping has had its equivalent in the Roman *stillicidium*, which prohibited building up to the very edge of an estate. This prohibition has been adopted by some states which follow the Roman civil law. From the Saxon custom arose the term "eavesdropper", i.e., any one who stands within "the eaves-dropping" of a house, hence one who pries into other's business or listens to secrets. At common law an eavesdropper was regarded as a common nuisance and was presentable at the court leet and indictable at the sheriff's tourn and punishable by fine and imprisonment for good behavior. Though the offence of eavesdropping still exists at common law there is no modern instance of prosecution or indictment.

EBBINGHAUS, HERMAN (1850-1909), German psychologist, was born in Birmen, studied at Berlin and rose to assistant professor there in 1886. He was given the chair at Breslau in 1894, was called to Halle in 1905 and died there in 1909.

Ebbinghaus was an innovator in the development of methods for experimenting on memory or rote learning. His results were published in *Psychologie des Gedächtnisses* in 1885 (English translation, 1913). He used nonsense syllables and took as a measure the number of repetitions required to learn them to the first perfect repetition. Aside from means used to justify the method, some of the more valuable results were to show that forgetting varied as the logarithm of the time elapsed, that distributing repetitions over different days reduced the number of repetitions

required, that the number of repetitions required for learning increased rapidly as the number of syllables in a series was increased. These experiments initiated a large series that have earned for our knowledge of learning.

Ebbinghaus wrote a two-volume survey of psychology that afforded the clearest and most comprehensive statements of psychology of its time. He is known also for an ingenious method of intelligence testing. (W B Py)

EBBW VALE, an urban district in the Ebbw Vale parliamentary division of Monmouthshire, Wales, 28 mi by road W of Monmouth. Pop (1951) 29,205. Area 10.7 sq mi. The town lies near the head of the Ebbw valley, nearly 1,000 ft above sea level and, like other mining towns of South Wales built in the second half of the 19th century, it straggles untidily along the valley. Christ Church (1870) is its chief building. Its position on the northern outcrop of the South Wales coal field made it first an important iron-smelting area and later a coal mining centre.

The extended use of coal and new processes in smelting made Ebbw Vale one of the most important steel centres in South Wales, but distance from the coast and trade depression in the 1930s caused great decline and distress. In 1935, however, a vast new steelworks, covering approximately 2½ mi by 2½ mi, was established on an old but much smaller foundation. It started working in 1938-39 and after 1945 it was enlarged. Its capacity ten years later was about 600,000 tons of sheet steel and tin plate a year. Attached to the Ebbw Vale steelworks are limestone quarries, brickworks and an iron ore field in Northamptonshire. The industries of the district also include coal mining.

EBEL, HERMANN WILHELM (1820-1875), German Celtic scholar, studied at Berlin and Halle, and, after holding other professional posts, became professor of comparative philology at Berlin. He died at Misdray on Aug. 19, 1875. His most important contribution to Celtic philology was his revised edition (1871) of Kaspar Zeuss's *Grammatica Celtica*. A selection of his papers was published in English as *Celtic Studies*, edited by Sullivan (1863).

EBEL, JOHANN GOTTFRIED (1764-1830), author of the first real guidebook to Switzerland, was born at Züllichau in Prussia on Oct. 6, 1764. He first visited Switzerland in 1790. As a result of three years' study he published *Anleitung auf die nützlichste und genussvollste Art in der Schweiz zu reisen* (Zürich, 1793). This was the best Swiss guidebook till "Murray" (1838). In 1801 he was naturalized Swiss and settled in Zürich. He died on Oct. 8, 1830.

Ebel's other works include *Schilderungen der Gebirgsvölker der Schweiz*, 2 vol. (Leipzig, 1798-1802), *Über den Bau der Erde im Alpengebirge*, 2 vol. (Zürich, 1808).

EBENACEAE, a family of dicotyledonous trees and shrubs including the ebony (*q.v.*) and other valuable timber trees. It has seven genera, with about 320 species, chiefly tropical or subtropical, and especially abundant in Malaya. The fruit is usually a berry. Several tropical species are cultivated for their edible fruits, while the Chinese persimmon (*Diospyros kaki*) is one of the most important fruits of China and Japan and is also cultivated in various parts of North America.

The family is represented in the United States by two species of persimmon (*q.v.*).

EBERBACH, a town of Germany, in the *Land* of Württemberg, Baden, on the Neckar river at the foot of the Katzenbuckel, 19 mi E of Heidelberg by the railway to Würzburg. The population in 1949 was 10,264.

It manufactures barrel hoops, chemicals and cigars and carries on by water an active trade in timber and wine. Eberbach was founded in 1227 by the German king Henry VII, who acquired the castle (now ruined) from the bishop of Worms.

EBERBACH, a famous Cistercian monastery of Germany, in the *Land* of Hesse, situated near Hattenheim in the Rheingau, 20 mi NW of Wiesbaden. Founded in 1116 by Archbishop Adalbert of Mainz, as a house of Augustinian canons regular, it was bestowed by him in 1131 upon the Benedictines, but was shortly afterward repurchased and conferred upon the Cistercian order.

The Romanesque church (consecrated in 1186) was despoiled during the Thirty Years' War and secularized in 1803.

EBERHARD (?-939), duke of the Franks, brother of Conrad, duke of Franconia and German king (911-918). In 915 Eberhard supported his brother against the rebel, Henry the Fowler of Saxony, but was defeated, and when Conrad died (918), Eberhard, at his brother's wish, carried to Henry the royal crown and sceptre, obtaining, however, for his support, almost complete independence for his own dukedom of Franconia. In 938 Eberhard rebelled against the new king, Otto the Great. He was defeated and fined, and his rebels condemned to carry dogs through the streets of Magdeburg. In the following year Eberhard, allied with the king's brother Henry and Gilbert of Lorraine, rebelled again, but was surprised and slain at Andemach on the Rhine.

EBERHARD, surnamed IM BART (*Barbatus*) (1445-1496), count and afterward duke of Württemberg, was born on Dec. 11, 1445, the second son of Louis I, count of Württemberg-Urach (d. 1450), and succeeded his elder brother Louis II in 1457. In 1468 he made a pilgrimage to Jerusalem. He visited Italy, became acquainted with some famous scholars, and in 1474 married Barbara di Gonzaga, daughter of Lodovico III, marquis of Mantua. In 1482 he made with his cousin Eberhard VI, count of Württemberg-Stuttgart, the treaty of Münsingen, by which the districts of Urach and Stuttgart into which Württemberg had been divided in 1437 were again united. The country was declared indivisible, and the right of primogeniture established. (*See* WÜRTTEMBERG.) At the diet of Worms in 1495 the emperor Maximilian I guaranteed the treaty, and raised Eberhard to the rank of duke. Eberhard was one of the founders of the Swabian league in 1488. He gave charters to the towns of Stuttgart and Tübingen, and introduced order into the convents of his land, some of which he secularized. He took a keen interest in the new learning and founded the University of Tübingen in 1477. In 1482 he again visited Italy and received the Golden Rose from Pope Sixtus IV. He died at Tübingen on Feb. 25, 1496. The succession passed to his cousin Eberhard, who became Duke Eberhard II.

See Rossini, *Leben Eberhards im Barie* (Tübingen, 1793), Bossert, *Eberhard im Bart* (Stuttgart, 1884).

EBERHARD, CHRISTIAN AUGUST GOTTLÖB (1766-1845), a versatile German writer, was born at Belzig, near Wittenberg, on Jan. 12, 1769. His best works are *Hannchen und die Kuchlein* (1822), a narrative poem in ten parts, and an epic on the Creation, *Der erste Mensch und die Erde* (1828). He died at Dresden on May 13, 1845.

His collected works (*Gesammelte Schriften*) appeared in 50 volumes in 1830-31.

EBERHARD, JOHANN AUGUSTUS (1739-1809), German theologian and philosopher, was born at Halberstadt, Lower Saxony, where his father was singing master at the church of St. Martin's, and teacher of the school of the same name. He studied theology at the University of Halle, and took orders. At Berlin he formed a close friendship with Nicolai and Moses Mendelssohn. His *Neue Apologie des Sokrates* (1772) hindered his preferment, but in 1774 he was appointed to the living of Charlottenburg, and in 1778 became professor of philosophy at Halle. He died on Jan. 6, 1809.

His works include *Amyntor, eine Geschichte in Briefen* (Berlin, 1782), written to counteract the influence of those sceptical and Epicurean principles in religion and morals then so prevalent in France, and rapidly spreading in Germany, *Über die Zeichen der Aufklärung einer Nation*, etc. (Halle, 1783), *Theorie der schönen Künste und Wissenschaften*, etc. (Halle, 1783, 3rd ed., 1790), *Allgemeine Geschichte der Philosophie*, etc. (Halle, 1788, 2nd ed. with a continuation and chronological tables, 1796), *Versuch einer allgemeinen-deutschen Synonymik*, 6 vol. (Halle and Leipzig, 1795-1802, 4th ed., 1852-53), long reckoned the best work on the synonyms of the German language (abridged, 1 vol., Halle, 1802), *Handbuch der Aesthetik* (Halle, 1803-05, 2nd ed., 1807-20).

See F. Nicolai, *Gedächtnisschrift auf J. A. Eberhard* (Berlin and Stettin, 1810), K. H. Jordens, *Lexicon deutscher Dichter und Prosaisten*.

EBERLEIN, GUSTAV (1847-1926) A German sculptor born on July 14, 1847, at Spickershausen, Hanover. He studied

at the Academy of Nuremberg and at Berlin under Blaeser, a follower of the classicist Rude. After a visit to Rome in 1873 where he was attracted to the Baroque he joined the group of sculptors led by Reinhold Begas. In 1887 he became a member of the Berlin academy, in 1893 he was made professor and in 1897 he held an important exultation of his work at the Berlin academy. His reputation rests chiefly upon his numerous public monuments, such as those of the emperor William I (Mannheim, Elberfeld and Altona), Bismarck (Krefeld), Richard Wagner (Berlin), Goethe (Rome), Queen Luise (Tilsit). He also executed religious pieces such as the groups representing the life of Adam and Eve, and mythological pieces such as Pygmalion and Galathea. In 1898 he presented the Eberlein museum to Münden in his native Hanover which contains a representative collection of his work. In 1892 he published *Amicus Bildners Seelenleben, Plastik, Malerei und Poesie*.

EBERLIN, JOHANN ERNST (1702-1762), German musician and composer, was born in Jettingen, Bavaria on March 27, 1702, and became court organist to the prince archbishop of Salzburg, where he died on June 21, 1762. Most of his compositions were for the church (oratorios, etc.), but he also wrote some important fugues, sonatas and preludes, and his pieces were at one time highly valued by Mozart.

EBERS, GEORG MORITZ (1837-1898), German Egyptologist and novelist, was born in Berlin on March 1, 1837. At Göttingen he studied jurisprudence, and at Berlin oriental languages and archaeology. He became in 1865 *dozent* in Egyptian language and antiquities at Jena, and from 1870 to 1889 he was professor at Leipzig. He had made two scientific journeys to Egypt, and his first work of importance, *Ägypten und die Bucher Moses*, appeared in 1867-68. In 1874 he edited the medical papyrus ("Papyrus Ebers") which he had discovered in Thebes (tr. by H. Joachim, 1890). Ebers early conceived the idea of popularizing Egyptology by means of historical romances. *Ene ägyptische Königstochter* (1864) had a great success. His subsequent works of the same kind—*Uarda* (1877), *Homo sum* (1878), *Die Schwestern* (1880), *Der Kaiser* (1881), of which the scene is laid in Egypt at the time of Hadrian, *Serapis* (1885), *Die Nitkra* (1887) and *Kleopatra* (1894), were also popular. Ebers also turned his attention to other historical periods—especially the 16th century (*Die Frau Burgermeisterin*, 1882, *Die Gred*, 1887)—without, however, attaining the success of his Egyptian novels. His other writings include a descriptive work on Egypt (*Ägypten in Wort und Bild*, 2nd ed., 1880), a guide to Egypt (1886) and a life (1885) of his old teacher, the Egyptologist Karl Richard Lepsius. He died at Tutzing, Bavaria, on Aug. 7, 1898.

Ebers's *Gesammelte Werke* appeared in 25 vols. at Stuttgart (1893-1895). Many of his books have been translated into English. For his life see *Die Geschichte meines Lebens* (Stuttgart, 1893), also R. Gosche, *G. Ebers, der Forscher und Dichter* (2nd ed., Leipzig, 1897).

EBERSWALDE, a town of Germany in the *Bezirk* of Frankfurt, 28 mi. N.E. of Berlin by rail, on the Finow canal and on the Berlin-Stettin railway. Pop. (1949) 40,615. It received its municipal charter in 1237 but was sacked during the Thirty Years' War. In 1747 Thuringian cutlers came to the town, but the cutlery industry has died out.

About 4 mi. to the north lies the Cistercian monastery of Chorn. The town has a 14th-century church, and there are also a forestry college and experimental station and a railway repair workshop. Industries include ironfounding and the making of roofing material and bricks.

EBERT, ADOLF (1830-1890), German romance philologist, was born at Kassel on June 1, 1830. He was professor of romance languages in Marburg, and from 1865 onwards in Leipzig, where he died on July 1, 1890. He wrote a standard work on mediæval literature, which is still indispensable to the student and has been the basis of much subsequent work by later writers, *Allgemeine Geschichte der Literatur im Abendlande* (3 vols., 1884-87). From 1850-53 he edited, with F. Wolf, *das Jahrbuch für romanische und englische Literatur*.

EBERT, FRIEDRICH (1870-1925), German politician,

was born in Heidelberg on Nov. 4, 1870, the son of an impecunious tutor. He was in early recruit to the Socialist movement, becoming a fluent speaker and a first class trade union organizer, suffering persecution and boycott for the cause. He moved to Hanover, and later on to Bremen, where he joined the staff of the local paper of the party, and, having dropped his trade as a saddler, became labour secretary for Bremen. From 1905 Ebert played an important part in the direction of the Socialist party. He entered the reichstag in 1912. A year later he became chairman of the party, which at that time was torn between the Orthodox and Revisionists, his common sense was considered a guarantee for keeping the party together.

At the outbreak of World War I, Ebert, deeply impressed by the danger of Russian victory, led the bulk of the party who voted for war credits. His common sense repudiated the optimistic pacifism of Haase and his followers, who later became the Independent Socialist party. He continued to strive, however, at home and abroad, especially at the Stockholm conference in June 1917, for a just peace. He became leader of the Majority Socialists in 1916 and chairman of the budget commission of the reichstag in 1918. Though disapproving of the Peace of Brest-Litovsk, he opposed strikes to bring about peace. In Feb. 1918 he tried hard and fairly successfully to put an end to the Berlin strike, which threatened to become a national calamity. For the part he played at that time he was attacked later on by the Independents as well as by the representatives of the old order.

After Ludendorff's collapse in Sept. 1918 Prince Max of Baden formed the first parliamentary cabinet. Ebert induced his party to join at a time when Ludendorff's insistence on an immediate demand for an armistice was already known. The negotiations about the armistice continued over a month. The suffering working classes began to be restless. When the plans to force a great naval battle became known, a mutiny took place at Kiel. Acting on Ebert's advice, Prince Max sent Noske to Kiel who succeeded in re-establishing order.

Ebert, knowing the historical attachment of the German people to monarchy, wanted a democratic parliamentary government, on English lines, but no republic. When the organized working men began to follow the Independents, Scheidemann intimated to Prince Max (Nov. 7) that the Socialists must withdraw from the cabinet, and that if the emperor did not abdicate by the 9th one of his sons, not the crown prince, should take his place. The emperor vacillated. By the 9th the masses had got out of hand. The monarchy collapsed, but the knowledge of the abdication had not the desired effect. Scheidemann proclaimed the German republic, and Prince Max offered Ebert the chancellorship, which he accepted. He formed a provisional government consisting of three Independents and two Majority Socialists besides himself.

From Nov. 1918 to Feb. 1919 it was touch and go whether Germany would be a democratic country or a soviet republic. The small group of German Bolsheviks, the Spartacus Union, led by Karl Liebknecht and Rosa Luxemburg, insisted that Russia's example should be followed, while the Independents did lip service to democracy, but wanted to postpone the elections. Ebert insisted on early elections for a constituent assembly, to give Germany a Democratic constitution. For nearly two months the government had no power. The Spartacists had armed their adherents and repeatedly tried to imprison Ebert and his colleagues. Ebert called Noske to Berlin, who succeeded in quelling the December and the January risings by means of quickly organized volunteers. When the struggle was over, the elections to the national assembly took place quietly. Democracy had won the day, thanks to Ebert and the moderate Socialists. It was but fitting that the assembly elected him the first provisional president of the German republic. Ebert stuck to his post when the Treaty of Versailles had to be signed and later when (March 1920), a military rising, the Kapp Putsch, took place. He left Berlin with his government to return after the general strike had forced the leaders to surrender.

Ebert's appointment as president was provisional. He wanted to withdraw from office at the appointed time (1922) and to subject himself to a proper election. He bowed, probably un-

wisely from his point of view, to the wishes of the majority of the reichstag, including the People's party, who asked him to accept office for a second term from their hands until 1925. When that term drew near its end, reactionary and radical forces had gained strength in Germany. This was shown by the result of the general election of May 1924. But by 1925, after stabilization had done its work, the situation had improved considerably, there appeared to be quite a fair chance that Ebert, if he chose to stand, might be re-elected.

By that time Ebert had dropped the party leadership. He remained on friendly terms with his party, but he considered himself the representative of the German people as a whole. He wielded the great but rather veiled power of the German president with consummate tact. His attitude when forming cabinets, and when reaching decisions was correct, constitutional and wise. He had gained the confidence of all persons with whom he came in contact. He had made the office of the president influential, though not conspicuous. This artisan who had not had the academic training so greatly valued in Germany succeeded in getting a firm grasp on foreign affairs. He saw a point quickly and he knew how to deal with men. Singularly modest and unassuming, his was the dominant influence, nevertheless, in the many crises the German republic had to pass through in the years that followed the peace.

But the fact that a plan man of the people was the head of the state did not commend itself to the reactionary elements of German society. A campaign of calumny was organized against him, accusing him of having fomented sedition and broken the back of the German army. He was forced to bring an action for libel against Herr Rothard, who had published in the *Mitteldeutsche Zeitung* a letter and footnote accusing Ebert of treasonable conduct in connection with the munition workers' strike in Jan. 1918. Rothard was found technically guilty, but the judge's finding was unfavourable to Ebert. As the judge's political bias was scarcely denied, the public, including the cabinet sided with Ebert. The central government and many state governments passed votes of confidence, the public assured him of their sympathy, but the strain practically killed Ebert, who had been suffering from repeated attacks of appendicitis. He did not wish to be operated upon before the case was over, and then it was too late. He died on Feb. 28, 1925, at Charlottenburg.

Ebert was a very fortunate combination of the lighthearted spirituality and sober shrewdness of the south German. He had faith in ideas and ideals, but he believed in action and in organization as well. There was passion in him, but there was common sense, there was strength in him, and there was sober suavity. He was by no means a genius towering head and shoulders above his fellow men. He was rather one of them, sharing their feelings and their qualities so that they could trust him completely, being just far enough ahead of them to make them follow him, the true leader for an incipient democracy.

EBERT, FRIEDRICH ADOLF (1791-1834), German bibliographer, was born at Taucha, near Leipzig, on July 9, 1791, the son of a Lutheran pastor. In 1813 he was attached to the Leipzig university library, and in 1814 was appointed secretary

to the Royal library of Dresden and, in 1827, after a short period of absence, chief librarian. The rich resources open to him in the Dresden library enabled him to undertake the work on which his reputation chiefly rests, the *Allgemeines bibliographisches Lexikon* (2 vols. 1821-30). This was the first work of the kind produced in Germany, and the most scientific published anywhere. Ebert was a contributor to various journals and took part in the editing of Ersch and Gruber's great encyclopaedia. He died at Dresden on Nov. 13, 1834, in consequence of a fall from the ladder in his library.

See the article in *Ersch und Grubers Encyclopädie*, and that in the *Allg. deutsche Biog.* by his successor in the post of chief librarian at Dresden, Schnorr von Carolsfeld.

EBERTH, KARL JOSEPH (1835-1926), bacteriologist, was born in Würzburg where he studied under Albrecht von Kolliker and Rudolf Virchow (qq.v.). On Aug. 5, 1865, he was appointed extraordinarius of pathology to Zurich. In 1869 he became ordinarius and in 1874 ordinarius for pathology. During 1881-95 he was at Halle, where, in 1894-95, he was director of the anatomy institute.

See J. Page, *Biographisches Lexikon hervorragender Aerzte* (Vienna, 1901), *Centralbl. f. allg. Path. u. Path. Anat.*, vol. 39, p. 226 (1927).

EBERWEIN, TRAUGOTT MAXIMILIAN (1775-1831), German violinist and composer, was born at Weimar on Oct. 27, 1775. He became a member of the court orchestra at Rudolstadt in 1797 and, in 1817, was made *Kapellmeister*. He had a part in the inception of the music festivals in Germany. He composed operas, cantatas, concertos, quartets, a mass and a *symphonie concertante*, of which the two operas *Claudine von Villa Bella* and *Der Jahrmarkt von Plundersweil* were most widely known.

Eberwein died at Rudolstadt on Dec. 2, 1831.

EBINGEN, a town of Germany, in the *Land* of Württemberg-Hohenzollern, on the Schmecha, a left-hand tributary of the Danube, 37 mi. W. of Ulm by rail. It manufactures velvets, knitted goods and precision tools. Pop. (1940) 14,732. Ebingen became a town in 1228 and part of Württemberg in 1805.

EBIONITES (Heb. עֲבִיּוֹנִים "poor men"), a name given to the ultra-Jewish party in the early Christian church. It is first met with in Irenaeus (*Adv. Haer.* 1, 26, 2), who sheds no light on the origin of the Ebionites, but says that while they admit the world to have been made by the true God (in contrast to the Demurge of the Gnostics), they held that Christ was a miraculously endowed man, and rejected Paul as an apostate from the Mosaic law to the customs and ordinances of which, including circumcision, they steadily adhered. A similar account is given by Hippolytus (*Haer.* vii, 35), who invents a founder named Elion. Origen (*Contra Celsum*, v, 61, *In Matt.* tom. xvi, 12) divides the Ebionites into two classes according to their acceptance or rejection of the virgin birth of Jesus, but says that all alike reject the Pauline epistles. This is confirmed by Eusebius, who adds that even those who admitted the virgin birth did not accept the pre-existence of Jesus as Logos and Sophia. They kept both the Jewish Sabbath and the Christian Lord's day, and held extreme millenarian ideas in which Jerusalem figured as the centre of the coming Messianic kingdom. Epiphanius with his customary confusion makes two separate sects, Ebionites and Nazarenes, both names refer to the same people (the Jewish Christians of Syria), the latter going back to the designation of apostolic times (*Acts* xv, 5), and the former being the term usually applied to them in ecclesiastical literature of the 2nd and 3rd centuries.

The origin of the Nazarenes or Ebionites as a distinct sect is very obscure, but may be dated with much likelihood from the edict of Hadrian which in 135 finally scattered the old church of Jerusalem. While Christians of the type of Aristo of Pella and Hegesippus, on the snapping of the old ties, were gradually assimilated to the great church outside, the more conservative section became more and more isolated and exclusive. "It may have been then that they called themselves the Poor Men, probably as claiming to be the true representatives of those who had been blessed in the Sermon on the Mount, but possibly adding to the name other associations." Out of touch with the main

stream of the church they developed a new kind of pharisaism. Doctrinally they stood not so much for a theology as for a refusal of theology, and, rejecting the practical liberalism of Paul, became the natural heirs of those early Judaizers who had caused the apostle so much annoyance and trouble. Though there is insufficient justification for dividing the Ebionites into two separate and distinct communities, labelled respectively Ebionites and Nazarenes, we have good evidence, not only that there were grades of Christological thought among them, but that a considerable section, at the end of the 2nd century and the beginning of the 3rd, exchanged their simple Judaic creed for a strange blend of Essenism, Gnosticism—as in the Clementine literature (*q.v.*) of the 3rd century—and Christianity.

See W. Beveridge, art. "Ebionism" in Hastings *Encyclopaedia of Religion and Ethics*, with refs., articles "Ebionites," "Elkasaites," "Clementine," in *Heterog-Heurck, Realencyclopaedie* with refs., & J. A. Hort, *Judaistic Christianity* (still valuable), Harnack, *History of Dogma* (Lang tr., vol. 1), Lightfoot, "St Paul and the Three" in *Commentary on Galatians* Otliky, *Doctrine of the Incarnation*, pt III, § 2, and the general church histories.

EBNER-ESCHENBACH, MARIE, FREIFRAU VON (1830-1916), Austrian novelist, was born at Zdislavitz in Moravia, on Sept. 13, 1830, the daughter of a Count Dubsky. She lost her mother in early infancy, but received a careful intellectual training from two stepmothers. In 1848 she married the Austrian captain, and subsequent field marshal, Montz von Ebner-Eschenbach, and resided first at Vienna, then at Klosterbruck, where her husband had a military charge, and after 1860 again at Vienna. Her first essay was with the drama *Maria Stuart in Schottland*, which P. E. Devrient produced at the Karlsruhe theatre in 1860, but she found her true sphere in narrative. Commencing with *Die Prinzessin von Banahen* (1872), she graphically depicted in *Bacena* (1876, 4th ed 1890) and *Das Gemeindegeld* (1887, 4th ed 1900) the surroundings of her Moravian home, and in *Lotti, die Uhrmachern* (1883, 4th ed 1900), *Zwei Comtessen* (1885, 5th ed 1898, Eng trans 1893), *Unschuldig* (1890, 5th ed 1900) and *Glaube und Liebe* (1893) the life of the Austrian aristocracy in town and country. Later books are *Neue Erzählungen* (1881, 3rd ed 1894), *Aphorismen* (1880, 4th ed 1895), *Parabeln, Märchen und Gedichte* (2nd ed 1893), *Aus Spätherbsttagen* (1901) and *Agave* (1903). Frau von Ebner-Eschenbach's wit and masterly character-drawing give her a foremost place among the German writers of her time. She died in Vienna on March 12, 1916.

See A. Bettelheim, 'Marie von Ebner Eschenbach und Julius Rodenberg', *Deutsche Rundschau*, Jahrg 46, pp 6-23 (Berlin, 1920), A. Bettelheim, *Maria von Ebner Eschenbach's Wirken und Vermächtnis* (Leipzig, 1920).

EBONITE, a substance manufactured by over-vulcanizing rubber. Pure rubber is mixed with about 40% of sulphur by rolling, and the resulting mass heated for from six to ten hours at a temperature of 150°. The valuable material thus obtained is a non-conductor of electricity and resists many chemical reagents. (See RUBBER PRODUCTION AND MANUFACTURE.)

EBONY, the wood of trees of the genus *Diospyros* (family Ebenaceae), widely distributed in the tropical parts of the world. The best kinds are very heavy, deep black, and consist of heart-wood only. On account of its colour, durability, hardness and susceptibility of polish, ebony is much used for cabinet work and inlaying, pianoforte keys, knife handles and turned articles. The best Indian and Ceylon ebony is furnished by *D. Ebenum*, which grows in abundance throughout the flat country west of Trincomalee in Ceylon. The tree is distinguished by the inferior width of its trunk, and its jet-black, charred-looking bark, beneath which the wood is perfectly white until the heart is reached. The wood is stated to excel all other varieties in the fineness and intensity of its dark colour. Although the centre of the tree alone is employed, reduced logs 1 to 3 ft in diameter can readily be procured. Much of the East Indian ebony is yielded by *D. melanoxylon* (Coromandel ebony), a large tree attaining a height of 60 to 80 ft, and 8 to 10 ft in circumference, with irregular rigid branches and oblong or oblong lanceolate leaves. The wood of *D. tomentosa*, a native of north Bengal, is black hard and of great weight. *D. montana*, another Indian species, produces

a yellowish grey soft but durable wood. *D. quassaia* is the tree from which is obtained the wood known in Ceylon as *Calamander*. Its closeness of grain, great hardness and fine hazel brown colour, mottled and striped with black, render it valuable for veneering and furniture making. *D. dendo*, a native of Angola, is a valuable timber tree 25 to 35 ft high, with a trunk 1 to 2 ft in diameter. The heart-wood is very black and hard and is known as black ebony, also as billet-wood, Gabun, Lagos, Calabar or Niger ebony. What is termed Jamaica or American ebony, and the green ebony of commerce, is produced by *Brya Ebenus*, a leguminous tree or shrub having a trunk rarely more than 4 ft in diameter, flexible spiny branches, and orange yellow, sweet-scented flowers. The heart-wood is rich dark brown, heavier than water, exceedingly hard and capable of receiving a high polish.

Ebony was among the articles of merchandise brought to Tyre (Ezekiel xxvii, 15), and Herodotus states (iii, 97) that the Ethiopians every three years send a tribute of 200 logs of it to Persia. By the ancients it was esteemed of equal value for durability with the cypress and cedar (see Pliny, *Nat. Hist.* xii, 9, xvi, 79). According to Solinus (*Polyhistor*, Paris, 1621), it was employed by the kings of India for sceptres and images, also, on account of its supposed antagonism to poison, for drinking cups. The hardness and black colour of the wood appear to have given rise to the tradition, alluded to by Southey (*Thalaba*, i, 22), that the tree produced neither leaves nor fruit, and was never seen exposed to the sun.

EBRARD, JOHANNES HEINRICH AUGUST (1818-1888), German theologian, was born at Erlangen on Jan. 18, 1818. Educated in his native town and at Berlin, he became *Privatdozent* at Erlangen (1841) and then professor of theology at Zurich (1844). From 1847-61 he held a similar post at Erlangen, where in 1875 he became pastor of the French reformed church. His chief works were *Christliche Dogmatik* (2 vols, 1851), *Vorlesungen über praktische Theologie* (1864), *Handbuch der Christl. Kirchen- u. Dogmengesch.* (4 vols 1865-66), *Apologetik* (1874-75, Eng trans 1886). He also edited and completed H. Olshausen's commentary, himself writing on the Epistle to the Hebrews, the Johannine Epistles and Revelation. He died at Erlangen on July 23, 1888.

EBRO (anc. IBERUS or HIBERUS), the only one of the five great rivers of the Iberian peninsula which flows into the Mediterranean. The Ebro, approximately 575 mi in length, rises at Fontibre, a hamlet among the Cantabrian mountains, in the province of Santander, at Reinoso, 4 mi E, it is joined on the right by the Hija, and then gains considerably in volume. It flows generally east by south through a tortuous valley as far as Miranda de Ebro. The chief cities on its banks are Logroño, Calahorra, Tudela, Saragossa and Caspe. Near Mora in Catalonia it forces a way through the coastal mountains and, passing Tortosa, falls into the Mediterranean about 80 mi SW of Barcelona. It drains an area of nearly 32,000 sq mi. Its principal tributaries are—(right) the Jalón with its affluent the Giloca, the Huerva, Aguas, Martín, Guadalope and Matafusa, (left) the Ega, Aragón, Nela, Gallego and the Segre with its system of confluent rivers. The Ebro and its tributaries have been utilized for irrigation since the Moorish conquest, the main stream becomes navigable by small boats about Tudela, but seafaring vessels cannot proceed farther than Tortosa. The great Imperial canal begun under the emperor Charles V, proceeds along the right bank from a point about 3 mi below Tudela, to El Buzo de Ebro, 5 mi below Saragossa, the irrigation canal of Fauste skirts the opposite bank for a shorter distance, and the San Carlos or New canal affords direct communication between Amposta at the head of the delta and the harbour of Los Alfaques.

EBROIN (d. 681), Frankish "mayor of the palace," was a Neustrian and wished to impose the authority of Neustria over Burgundy and Austrasia. In 656, at the moment of his accession to power, Siegfert III, the king of Austrasia, had just died, and the Austrasian mayor of the palace, Grimoald, was attempting to usurp the authority. The great nobles, however, appealed to the king of Neustria, Clovis II, and unity was re-established. But in spite of a very firm policy Ebrouin was unable to maintain

this unity, and while Clotaire III, son of Clovis II, reigned in Neustria and Burgundy, he was obliged in 660 to give the Austrasians a special king, Childeric II, brother of Clotaire III, and a special mayor of the palace, Wulfoald. His efforts to maintain the union of Neustria and Burgundy were opposed by the great Burgundian nobles, who rose under St Leger (Leodegar), bishop of Autun, defeated Ebriorn, and interned him in the monastery of Luxeuil (670). Soon, however, Leger was defeated by Wulfoald and the Austrasians, and was himself confined at Luxeuil in 673. Ebriorn and Leger then left the cloister. Each looked for support to a different Merovingian king, Ebriorn even proclaiming a false Merovingian as sovereign. Leger was besieged in Autun, was forced to surrender and had his eyes put out, and, on Oct. 12, 678, he was put to death after undergoing prolonged tortures. The church honours him as a saint. After his death Ebriorn became sole and absolute ruler of the Franks, imposing his authority over Burgundy and subduing the Austrasians, whom he defeated in 678 at Bois du-Fay, near Laon. He was assassinated in 681.

See *Liber historiae Francorum*, edit by B. Krusch, in *Mon Germ hist script* ser. Merov. vol. II, *Vita sancti Leodegarii*, by Ursinus, a monk of St. Maixent (Migne, *Patr. Latina*, vol. xcvi), "Vita metrica" in *Poetas Latini aevi Carolini*, vol. II (*Mon Germ hist*), J. B. Pitra, *Historie de Saint Leger* (1846), and J. Friedrich "Zur Gesch. des Hausmeiers Ebriorn," in the *Proceedings of the Academy of Munich* (1887, pp. 42-61).

EBURACUM or **EBORACUM** (probably a later variant), Roman name of York (*q.v.*) in England. Established about 75-80 as fortress of the Ninth legion and garrisoned (after the annihilation of that legion about A.D. 118) by the Sixth legion, it developed outside its walls a town of civil life, which later obtained Roman municipal rank and in the 4th century was the seat of a Christian bishop. The fortress and town were separated by the Ouse. On the left bank, where the minster stands, was the fortress, of which the walls can be partly traced. At the west corner a bastion of the 4th century type (the so-called Multangular Tower) survives, while at the east corner an internal tower of earlier date has been uncovered. The municipality occupied the right bank near the present railway station. The place was important for its garrison and as an administrative centre. The name is preserved in the abbreviated form *Ebor* in the official name of the archbishop of York, but the philological connexion between *Eboracum* and the modern name *York* is doubtful and has probably been complicated by Danish influence (S. N. M.).

ÊÇA DE QUEIROZ, JOSE MARIA (1843-1900), Portuguese novelist, was born at Villa do Conde, his father being a retired judge. Entering the consular service in 1872, he went to Havana, and, after a tour in the United States, was transferred two years later to Newcastle-on-Tyne and in 1876 to Bristol. In 1888 he became Portuguese consul-general in Paris and died there in 1900.

Queiroz in 1870, in collaboration with Ramalho Ortigão, wrote a sensational story, *The Mystery of the Centre Road*, but the first publication which brought him fame was *The Farpas*, a series of satirical and humorous sketches of various phases of social life. At this period French literature and French politics interested Queiroz profoundly, while he ignored the *belles-lettres* of his own country and its public affairs. He founded the Portuguese Realist-Naturalist school, of which he remained for the rest of his life the chief exponent, by a powerful romance, *The Crime of Father Amaro*, written in 1871 at Leiria but only issued in 1875. During a stay in England he produced two masterpieces, *Cousin Basil* and *The Moura*, but they show no traces of English influence, nor again are they French in tone, for his disillusionment progressed and was complete when he went to Paris and had to live under the regime of the Third Republic. Seeking in *Nullus*, the novelist became chronicler, critic and letter writer as well as in all these capacities Queiroz displayed a spontaneity, power and artistic finish unequalled in the literature of his country since the death of Garrett. Many of his pages descriptive of natural scenery such as the episode of the return of Torres in *The City and the Mountains*, are classic examples of Portuguese prose. He manifested a predilection for middle-class type-

conditions.

Queiroz also wrote a number of short stories, some of which have been printed in a volume under the title of *Contos*. The gems of this remarkable collection are perhaps *The Peculiarities of a Fair-haired Girl*, *A Lyric Poet*, *José Mathias* and *The Corpse*.

One of Queiroz's romances and two of his short stories have been published in English. An unsatisfactory version of *Cousin Basil*, under the title *Dragon's Teeth*, appeared at Boston, U.S.A., in 1880, while *Sweet Miracle* has had three editions in England and one in America, and there is also a translation of *O Defunto* (*The Corpse*), under the name of *Our Lady of the Pillar*. See J. Pereira de Sampaio *A Geração Nova—Os Novellistas* (Oporto, 1886), and Senhor Batalha Reis's preface to some prose fragments of Queiroz edited by him and named *Prosas Barbaras* (Oporto, 1903).

ÉCARTÉ (Fr. "separated," "discarded"), a game of cards, invariably played for a stake. It was probably first played in Paris, in the first quarter of the 19th century. It is one of a family of "short" games developed from *trionphe* or *trump* (also called *French-ruff*), and is related to the American *exche*, the British *Napoleon*.

The play is two hand, though three players frequently participate by *chouette* (*q.v.*). The pack of 32 cards is used, the cards of each suit ranking K (high), Q, J, A, 10, 9, 8, 7. Five cards are dealt to each player, in rounds of two and three at a time or vice versa. The 11th card is turned up for trump. If it is a king, dealer scores one point. After looking at his hand, non-dealer either *stands* or *proposes*. If he stands, the cards are played forthwith. If he proposes, dealer may *refuse*, equivalent to standing, or *accept*. In the latter event, each player discards as many cards as he wishes (nondealer must discard at least one, dealer may discard none) and the dealer then gives each in turn enough cards from the pack to restore his hand to five. Repeated proposals and acceptances may be made, but when the pack is exhausted the hands must be played. The card turned for trump is never changed, it fixes the trump for that deal. Either player holding the king of trumps may score one point by showing it before the opening lead.

Nondealer invariably makes the first lead. Each lead requires the other hand to follow suit if able, and also to win, if able. A trick is won by the higher trump if any is played, otherwise by the higher card of the suit led. The winner of a trick leads to the next. The object of play is to win three or four tricks, counting one point, or all five tricks (*vole*), counting two. If the original hands are played, and the one who stood fails to take three tricks, his opponent scores two points (for three, four, or five tricks). Game is five points.

Skill at *Écarté* consists chiefly in (a) judgment when to play, (b) inferences as to the adverse cards after a proposal has been accepted. The first matter has been reduced to a complete calculation of the *jeux de règle* (regulation hands) that have at least a 2:1 chance to win three tricks. The following table is condensed from *Traité de L'Écarté*, by Émile Dormoy.

JEUX DE RÈGLE (for nondealer)

Plan	suits	1st	2nd	3rd
A	Hands with no trumps	K, A	• K	K
		Q, J	K	K
		Q, J	Q, J	K
		K, Q	K	Q
		K, J	K, J	Q
B	Hands with one trump	K, Q, 7	K	
		K, 8, 7	K	
		Q, J, A	J	
		K, A	K, 7	
		Q, J	K, 7	
		Q, J	Q, A	
		K, Q	Q	7
		K, A	K	7
		K, 7	K	A
		K	K	9, 8
		Q, T	T	7

C Hands with two trumps	K,	7	9		
	J,	10	10		
	A,	10	A		
	J		J	J	
		7	Q	Q	
D Hands with three trumps		8,	7		
			9		
E Any hand with four or five trumps					

The first card listed in each hand is the correct opening lead. See Ch. Van-Tenre and Louis Delanoue, *Traité du jeu de l'écarte* (Paris, 1845), translated in Bohn's *Handbook of Games* (1850) ("Cavendish," *The Laws of Ecarte, adopted by the Turf Club, with a Treatise on the Game* (London, 1878); *Pocket Guide to Ecarte* (1887); and Emile Dormoy, *Traité de l'Ecarte* (Paris).

ECBATANA (Old Persian *Hammatana*) situated at the foot of Mount Orontes (Alwand), was the capital of Media and the summer residence of the Achaemenian kings, being afterwards also the Parthian capital. According to the Greeks (e.g., Herodotus, i, 96 ff.), it was founded by Deioces the Mede, but it appears to be mentioned in an inscription of Tiglath-Pileser I, who was much earlier. Though surrounded by seven walls and possessing a citadel that was at the same time a treasure house, it was captured by Cyrus from Astivages in 550 B.C. and was taken from the last Achaemenian by Alexander in 330 B.C. Among the Achaemenian relics found in the city in recent times is a trilingual inscription in which Artaxerxes Mnemon celebrated the building of a palace. The Ecbatani at which, according to Herodotus (iii, 64), Cambyses died, is probably a blunder for Hamath.

See Perrot and Chippiez, *History of Art in Persia* (Eng. trans. 1892), M. Druart, *L'Art antique de la Perse*, pt. 1 (1884), J. de Morgan, *Mission scientifique en Perse*, ii (1894), W. Guger and E. Kuhn *Grundriss der iranischen Philologie*, ii (1896-1901). See also HAMADAN and PERSIA. *History*. (R. LEV)

ECCARD, JOHANN (1553-1611), German composer of church music, was born at Mühlhausen, Thuringia, in 1553. He studied at Munich under Orlando Lasso in whose company he is said to have visited Paris. In 1581, he became assistant conductor, and in 1599 conductor, at Königsberg, to Georg Friedrich, margrave of Brandenburg-Anspach, and in 1608 he was called by the elector Joachim Friedrich to Berlin as chief conductor. He died at Königsberg in 1611. Eccard's works consist exclusively of vocal compositions, such as songs, sacred cantatas and chorales for four or five and sometimes for seven, eight, or even nine voices. Their polyphonic structure is remarkable. At the same time his works are instinct with a spirit of true religious feeling. Eccard and his school are connected with the history of the Reformation and "Ein feste Burg" is only one of many Lutheran hymns for which he provided memorable settings.

See K. G. A. von Winterfeld, *Der Evangelische Kirchengesang* (1843), and G. Reichmann, *Joh. Eccards weltliche Werke* (Hadelberg, 1922).

ECCELINO DA ROMANO (1104-1250), Ghibelline leader, and supporter of the emperor Frederick II, was born on April 25, 1104, of a German family settled in Italy in the first half of the 11th century. They were lords of Romano, near Padua. In 1236, at the head of a band of Ghibellines, Eccelino seized Verona and became *podestà* of the city. He lost Verona, but regained it in 1240, and in 1242 Frederick II ordered a charter confirming him in his possessions. In 1247 the emperor gave him the government of Vicenza, Padua and Treviso, and on Nov. 27, 1257, he shared in the victory over the Lombards at Corbassio. In 1258 he married Frederick's natural daughter, St. Elizabeth, and in the same year was crowned as king of the church of Treviso, but in the same year was excommunicated by Pope Gregory IX. After Frederick's death in 1250 he supported his son, the German king Conrad IV. His cruelties had however aroused general disgust, and in 1254 he was again excommunicated. In 1256 Pope Alexander IV proclaimed a crusade against him, which was led by Philip archbishop of Ravenna. Eccelino lost Padua, but on

Sept. 1, 1258, he defeated his enemies at Torricella. At Cassano on Sept. 27, 1259, Eccelino was wounded and taken prisoner. Enraged at his capture, he tore the bandages from his wounds, refused to take food and died at Soncino on Oct. 7, 1259. In the following year his brother Albert was put to death, and the Romano family became extinct. Eccelino, sometimes called the *tyrant*, acquired a reputation for cruelty that gained him a place in Dante's *Inferno*, but his unswerving loyalty to Frederick II contrasts favourably with many of his contemporaries. Eccelino is the subject of a novel by Cesare Cantu and of a drama by J. Eichendorff.

See J. M. Gittermänn, *Ezzelino da Romano* (Freiburg, 1890), S. Mitis, *Storia d'Ezzelino IV da Romano* (Maddaloni, 1891), and F. Steve, *Ezzelino von Romano* (Leipzig, 1909). See also HAMPE, *Mittelalt. Geschichte* (1922).

ECCENTRIC, from two Greek words, meaning literally "out from the centre," and thus used to connote generally any deviation from the normal. In ancient astronomy the word denotes a circle round which a body revolves, but whose centre is displaced from the visible centre of motion. In early times the ellipses in which the planets revolve around the sun as focus could not be distinguished from circles, but the unequal angular motion due to ellipticity was observed. A point, however, can be

DIAGRAM OF AN ECCENTRIC USED IN STEAM ENGINES SHOWING PARTS. The eccentric converts rotary into reciprocating motion and moves the valve controlling the flow of steam and the exhaust to and from the cylinder.

found on the major axis of the ellipse (namely the empty focus) such that the angular velocity of the planet about it is nearly constant. It was therefore supposed that the deferent of the epicycle of the planet moved uniformly in a circle about this point. For eccentric angle see ELLIPSE.

In engineering, an eccentric is a disc mounted out of centre on a shaft, to give reciprocating movement to a lever, it is an agent much used in steam engines and other mechanisms. It is fixed with a key or screw on to the crankshaft and moves the valve rod to and fro to control the flow of steam and the exhaust. Using two eccentrics with link-motion, the engine can be reversed, and the steam used expansively, e.g., in locomotives, when a good rate of speed has been reached. A reversing eccentric is one with a slotted fitting whereby it can be moved in relation to the shaft, thus reversing the action of the valve to run the engine in the opposite direction. This is but little used, however, the link motion having preference. Eccentrics are also fitted on the poppet valve steam engines, being located then on a shaft running parallel with the cylinder. An eccentric is often employed to work a pump and operate the slides of certain machines, such as the oil-shutter, and punching. Eccentrics are used to work the valves of powerful rock and stone crushers, and to close quick-acting clamps in lifting mechanisms and in check shipping.

ECCHELLENIS (ECCHELLENIS) ABRAHAM (c. 1600-1664), a learned Maronite was born at Ibel, Syria. Founded at Rome, he became professor of Arabic and Syriac in the college of the Propaganda at Rome and in 1626 professor at the College de France. Invited to take part in the preparation of an Arabic version of the Bible, Echellensis returned in 1652 to Rome where he died. Of his Latin translations of Arabic works, the most important was the *Chronicon Orientale* of Ibn al-Rahbi.

(Paris, 1653), a history of the patriarchs of Alexandria. With Giovanni Borelli he wrote a Latin translation of the 5th, 6th and 7th books of the *Comics* of Apollonius of Perga (1661). He also published *Eutychius vindicatus, sive Responso ad Saldem Origines* (Rome, 1661). To Le Jay's polyglot Bible he contributed the Arabic and Latin version of Ruth and the Arabic version of the third book of Maccabees.

ECCLES, JOHN (1650–1735), English composer, son of Solomon Eccles, from whom he learned music. Beginning about 1681, he wrote music for the theatre for two decades, contributing music to more than 40 plays during that period. He became a member of the king's band in 1694 and master in 1700. He won second prize in a competition for the best composition to Congreve's "Judgment of Paris," wrote music for Queen Anne's coronation and published a collection of his own widely popular songs. He died on Jan. 12, 1735, at Kingston in Surrey.

ECCLES, SOLOMON (1618–1683), English musician and Quaker, was born in London in 1618. Beginning about 1647 he taught and composed music. He became a Quaker about 1660, and, because music was considered inconsistent with the tenets of Quakerism, publicly burned all his instruments and music books on Tower Hill. Taking up the trade of shoemaking, he began a somewhat spectacular personal crusade against what he considered to be the evils of his time. His extravagant course of action, which included violent protests in "popish" churches and walks through the streets unclothed with a brazer of burning brimstone on his head, indicated an unbalanced mind and led to numerous floggings and periods of imprisonment. In 1671 he went to the West Indies with a missionary group of Friends led by George Fox. The following year he travelled to New England and was reportedly banished after his arrest in Boston. In Barbadoes in 1680, he was prosecuted for sedition and blasphemy and later expelled from the colony. He is believed to have returned to his musical interests in later years and is credited with certain contributions to the "Division Violin." He died on Feb. 11, 1683, and was buried at Spitalfields.

ECCLES, a municipal and parliamentary borough of Lancashire, Eng., 4 mi W of Manchester, of which it forms practically a suburb. Pop. (1951) 43,927. Area 5.3 sq mi. It lies on the north bank of the Manchester Ship canal.

Before the Reformation the monks of Whalley abbey had a grange there at what is still called Monks' hall, and in 1864 many thousands of silver pennies of Henry III and John of England and William I of Scotland were discovered near the spot. From early times "wakes" were held at Eccles, and bullbaiting, bearbaiting and cockfighting were carried on. Under Elizabeth I these festivals were abolished but were revived under James I and maintained until late in the 19th century. The church of St. Mary, believed to date from the 12th century, has been much restored. There are several modern churches and chapels and a town hall. Among a variety of industries the chief are engineering and metalworking. Eccles cakes, made of pastry with currants, have a wide reputation. The town was incorporated in 1892. Eccles and the borough of Swinton and Pendlebury form the borough constituency of Eccles, which returns one member.

ECCLESFIELD, township, Wortley rural district, Penistone parliamentary division, West Riding of Yorkshire, Eng., 5 mi N of Sheffield. Pop. (1954 est.) 30,150. The church of St. Mary is Perpendicular on a Norman foundation, it contains excellent woodwork and formerly bore the familiar title of the "Minster of the Moors." Ecclesfield was the seat of a Benedictine priory in the 12th century which passed to the Carthusians in 1386. There are coal mines, paper mills and iron foundries, fire and tool factories and brick and flowered clay works.

ECCLESHALL, a market town in the Stafford and Stone parliamentary division of Staffordshire, Eng., 7 mi NW of Stafford by road. Pop. (1951) of town 13,010, of parish 14,740. Holy Trinity church is principally Early English and has fine stained glass. Several shops on Lichfield are situated there is Eccleshall castle was the episcopal residence from the 13th century until 1867. Of the old castle only the walls enclosing the moat remain the main buildings being relatively modern. Eccle hill though chiefly

residential and agricultural with a livestock market, has a few light industries including the manufacture of clothing and agricultural implements.

ECCLESIA, the general assembly of freemen in Athens (*ἐκκλησία*). In the primitive state the king was absolute, though his great nobles in council (*see* Boule) were able to influence him considerably. In the earliest times the free people, *i.e.*, the fighting force of the state were called together to ratify the decisions of the king. In Athens, as in Rome, where the Plebs obtained the codification of the laws (the Twelve Tables), it was owing to the growing power of the people meeting in the agora that Dracon was entrusted with the task of publishing a code of law.

The precise powers which Solon gave the people are not known. The executive power (*see* Archon) was still vested in the Eupatrid class (*see* Eupatridae). It seems that, though the officials of the state were still Eupatrid, the Ecclesia elected those of the Eupatrids whom they could trust, and had the right of criticizing their official actions. Solon admitted the Thetes (*see* Solon) to the Ecclesia, thus recognizing them as citizens. Under Cleisthenes (*qv*) the Ecclesia remained the sovereign power. The relation of Boule and Ecclesia in the Cleisthenic democracy was of the greatest importance. The Ecclesia alone, a heterogeneous body of untrained citizens, could not have drawn up intelligible measures, the preliminary drafting was done by the Boule (*qv*). In the 5th century the functions of the Ecclesia and the popular courts of justice were increased by the exigencies of empire. At the beginning of the 4th century B.C. the system of payment was introduced (*see* below). Under Roman rule the powers of the Ecclesia and the popular courts were much diminished. They still assembled to elect *strategoi*, and, under Hadrian, had some small judicial duties, but as a governing body the Ecclesia died when Athens became a *civitas libera* under Roman protection.

Constitution and Functions—Throughout the period of Athenian greatness the Ecclesia was the sovereign power. The regular place of meeting was the Pnyx. From the 5th century it met sometimes in the theatre, which in the 3rd century was the regular place. Special meetings were held at times at Paeonia. Certain meetings, however, for voting ostracism (*qv*) and on questions affecting individual status took place in the agora. Meetings were (1) ordinary, (2) extraordinary, and (3) convened by special messengers (*kuriai sunklētoi* and *kataklētoi*), these last being called when it was desirable that the country people should attend. At ordinary meetings the attendance was practically confined to Athenian residents. According to Aristotle there were four meetings in each of the prytanies, probably only the first of these was called *kuria*. In the *kuria ekklesia* of each month took place the *Epekeirotoma* (monthly inquiry) of the state officials, and if it proved unsatisfactory a trial before the Heliaea (supreme court) was arranged, the council reported on the general security and the corn supply. In the sixth prytany of each year at the *kuria ekklesia* the question whether ostracism should take place that year was put to the vote. On occasions of sudden importance the herald of the council summoned the people with a trumpet, and sometimes special messengers were despatched to "bring in" the country people (*kataklētoi*).

All Athenians over the age of 18 years were eligible to attend the assembly, save those who for some reason had suffered *atimia* (loss of civil rights). The introduction of pay, which belongs to the early years of the 4th century, was a device to secure a larger attendance. The rate rose from one to two obols and then to three obols, while at the time of Aristotle it was one and a half drachmas for the *kuria ekklesia* and one drachma for other meetings.

Procedure—The proceedings opened with formalities the purification, the curse against all who should deceive the people, the report as to the weather omens. The assembly was always dismissed if there were thunder, rain or an eclipse. These formalities over the Praxinos commenced the *probouleuma* of the council, without which the Ecclesia could not debate. This recommendation either submitted definite proposals or merely brought the agenda before the assembly. It *examinated* the business

in hand, which otherwise must often have been beyond the grasp of a miscellaneous assembly. After the reading, a preliminary vote was taken on the question whether the council's report should be accepted *en bloc*. If it was decided to discuss, the herald called upon people to speak. Any person, without distinction of age or position, might obtain leave to speak, any member of the assembly (1) might propose an amendment, (2) might draw up a new resolution founded on the principal motion, (3) might move the rejection of the motion and the substitution of another, (4) might bring in a motion asking the council for a recommendation on a particular matter, (5) might petition the council for leave to speak on a given matter to the assembly. Voting usually was by show of hands and the decision of the assembly had absolute validity. These decisions were deposited in the *Métroon* where state documents were preserved, peculiarly important decrees were inscribed also on a column (*stelē*) erected on the Acropolis. The power of the council was far from sufficient. The real check on the vagaries of amateur legislators was the *graphē paranómōn*. Any man was at liberty to give notice that he would proceed against the mover of a given resolution. A trial in a Hellenic court was then arranged, and the plaintiff had to prove that the resolution in question contravened an existing law. If this contention was upheld by the court, the resolution was annulled and the defendant had to appear in a new trial for the assessment of the penalty, which was usually a fine. Three convictions under this law involved a certain loss of rights, the loser could no longer move a resolution in the Ecclesia. After the lapse of a year the mover of a resolution could not be attacked in the 4th century the *graphē paranómōn* took the place of *Ostracism*.

Revision of Laws—In the 4th century the assembly annually took a general vote on the laws, to decide whether revision was necessary. If the decision was in favour of alteration, any private citizen might put up notice of amendments. The *nomothetai*, a panel selected by the *prytanes* from the *Hehaea*, heard arguments for and against the changes proposed and voted accordingly, new laws so passed were liable to the *graphē paranómōn*.

Judicial Functions—The Ecclesia heard cases of *probolē* and *eisangelia* (impeachment—see *Greek Law*). The *probolē* was an action against sycophants and persons who had not kept their promises to the people or had disturbed a public festival. The verdict went by show of hands, but no legal consequences ensued, if the plaintiff demanded punishment he had to go to the *Hehaea*, which was not bound by the previous vote in the Ecclesia. Cases of *eisangelia* in which the penalty exceeded the legal competence of the council came before the Ecclesia in the form of a *probolēuma*. To prevent vexatious accusations, the accuser who failed to obtain one fifth of the votes was fined 1,000 drachmas (£40).

Summary—The Ecclesia had absolute power save for the *graphē paranómōn*, which constituted the *dicasteries* (jurymen) in one sense the sovereign power in the state. It dealt with all matters, home and foreign. It was in practice by no means a representative assembly. The phrase used to describe a special assembly (*kataklitos ekklēsia*) shows that ordinarily the country members did not attend. Thucydides says that 5,000 was the maximum attendance, though he is referring to the time when the number of citizens was reduced owing to the plague and the Sicilian expedition. The Ecclesia did not exercise the power of law-making (*nomothētia*) in the strict sense but passed *psephismata*, which would in many cases be regarded as law in the modern sense. The Ecclesia also was concerned with the supervision of administration.

Whibley, *Companion to Greek Studies* (1925), with useful bibliography.

ECCLESIASTES, one of the Wisdom Books of the Old Testament (see *WISDOM LITERATURE*). The book, as it stands, is a collection of discourses, observations and aphorisms. The

precise meaning of the Hebrew title is not certain. The Greek *ecclesiastes* means one who takes part in the deliberations of an assembly (*ecclesia*), a debater or speaker in an assembly (Plato, *Gorgias*, 452 D), and this is the general sense of the Hebrew word *Kohleth* is employed in the book as the name of a sage. It is intended to represent him as a member of an assembly (*Kahal*)—not the Jewish congregation, but a body of students or inquirers, such as is referred to in *vu* 9-11, a sort of collegium, of which he was the head, and as instructor of this body he gives his criticism of life. The author begins, indeed, by identifying his sage with King Solomon (1: 1, 2, 11, 12), but he soon abandons this literary device, and speaks in his own name. The rendering "preacher" has a misleading connotation.

Contents—In the book as we have it there is no orderly exposition of a theory, it rather has the appearance of a collection of extracts from a sage's notebook. It is, however, characterized throughout (except in some later additions) by a definite thought, and pervaded by a definite tone of feeling. The keynote is given in the classic phrase with which the discussion opens and with which it closes "Vanity of vanities (i.e., absolute vanity), all is vanity!" Life, says the author, has nothing of permanent value to offer. His attitude is not one of bitterness but of calm hopelessness, with an occasional tinge of disgust or contempt. He fancies that he has tried or observed everything in human experience, and his deliberate conclusion is that nothing is worth doing. He believes in an all-powerful but indifferent God, and is himself an observer of society, standing aloof from its passions and ambitions, and interested only in pointing out their emptiness.

This general view is set forth in a number of particular observations.

1 His fundamental proposition is that there is a fixed, unchangeable order in the world, a reign of inflexible law (1: 4-11, 11: 1-11, 14, 15, 17: 13, 18: 5-9), natural phenomena, such as sunrise and sunset, recur regularly, for everything in human experience a time has been set, all its phenomena are to be regarded not as utterances of a living, self-directing world, but as incidents in the work of a vast machine that rolls on for ever, there is an endless repetition—nothing is new, nothing is lost, God, the author of all, seeks out the past in order to make it once more present, it is impossible to add to or take from the contents of the world, impossible to change the nature of things, the result is unspeakable weariness—a depressing series of sights and sounds. No goal or purpose is discoverable in this eternal round. To what end was the world created? It is impossible to say. Such is Kohleth's view of life, and it is obvious that such a conception of an aimless cosmos is thoroughly non-Jewish, if we may judge Jewish thought by the great body of the extant literature.

2 Further, says Kohleth, man is impelled to study the world, but under the condition that he shall never comprehend it (*vu* 11, 17: 23, 24, 18: 16, 17). God has made the world an object of man's thought, yet so that man can never find out the work that God has done (*vu* 11). The reference seems to be not so much to the variety and complexity of phenomena as to the impossibility of construing them rationally or in such a way that man may foresee and provide for his future. Man is in the clutches of fate (*vu* 11, 12), there is no observable relation between exertion and result in life, the race is not to the swift nor the battle to the strong.

3 Human life, Kohleth declares, is unsatisfying. He inquired, he says, into everything that is done by men under the sun (1: 12-17), God has inflicted on men a restless desire for movement and work, yet life is but a catalogue of fruitless struggles. He gives a number of illustrations. In his character of king he tried all the bodily pleasures of life (*vu* 2-11), all these he set himself to enjoy in a rational way, but, when all was done, he surveyed it only to see that it was weary and unprofitable. Dropping the role of Solomon and speaking as an observer of life, the author declares (*vu* 4) that the struggle for success is the result of rivalry among men, which has no worthy outcome. The securing of riches is a fallacious achievement—naked man comes into the world, naked he goes out.

If wealth be thus a vain thing, yet a sage might be supposed to find satisfaction in wisdom, that is, practical good sense and sagacity, but this also the author puts aside as bringing no lasting advantage, since a wise man must finally give up the fruit of his wisdom to someone else, who may be a fool, and in any case the final result for both fools and wise men is the same—both are forgotten (i 12-23). The whole constitution of society, in fact, seems to the sage a lamentable thing, the poor are oppressed, the earth is full of their cries, and there is no helper (iv 1), strange social upheavals may be seen, the poor set in high places, the rich cast down, slaves on horseback, princes on foot (x 5-7). He permits himself a sweeping generalization (vii 25-28), human beings as a rule are bad, one may occasionally find a good man, never a good woman—woman is a snare and a curse.

4 The natural outcome of these experiences of the author is that he cannot recognize a moral government of the world. He finds, like Job, that there are good men who die prematurely notwithstanding their goodness, and bad men who live long notwithstanding their badness (vii 15), and in general there is no moral discrimination in the fortunes of men (viii 14, x 2).

5 There is no sacredness or dignity in man or in human life, man has no pre-eminence over beasts, seeing that he and they have the same final fate, die and pass into the dust, and no one knows what becomes of the spirit, whether in man's case it goes up to heaven, and in the case of beasts goes down into Sheol—death is practically the end all, and so poor a thing is life that the dead are to be considered more fortunate than the living, and more to be envied than either class is he who never came into existence (iv 2, 3). It is a special grievance that the wicked when they die are buried with pomp and ceremony, while men who have acted well are forgotten in the city (vii 10).

6 That the author does not believe in a happy or active future life appears in the passage (iv 2, 3) quoted above. The old Hebrew view of the future excluded from Sheol the common activities of life and also the worship of the national god (Isa xxxviii 18), he goes even beyond this in his conception of the blankness of existence in the underworld. The living, he says, at least know that they shall die, but the dead know nothing—the memory of them, their love, hate, envy, perishes, they have no reward, no part in earthly life (ix 5, 6), there is absolutely no knowledge and no work in Sheol (ix 10). His conclusion is that men should do now with all their might what they have to do, the future of man's vital part, the spirit, is wholly uncertain.

7 His conception of God is in accord with these views. God for him is the creator and ruler of the world, but hardly more, he is the master of a vast machine that grinds out human destinies without sympathy with man and without visible regard for what man deems justice—a being to be acknowledged as lord, not one to be loved. There can thus be no social contact between man and God, no communion of soul, no enthusiasm of service. Moral conduct is to be regulated not by divine law (of this nothing is said) but by human experience. The author's theism is cold, spiritless, without influence on life.

If now the question be asked what purpose or aim a man can have, seeing that there is nothing of permanent value in human work, an answer is given which recurs, like a refrain, from the beginning to the end of the book, and appears to be from the hand of the original author, after every description of the vanity of things comes the injunction to enjoy such pleasures as may fall to one's lot (i 24, 25, ii 12, 13, 22, v 18, 19, viii 15, ix 7-10, xi 7, xii 7). The opportunity and the power to enjoy are represented as being the gift of God, but this statement is not out of accord with the author's general position, which is distinctly theistic.

There are many sayings in the book that appear to be at variance with its fundamental thought. For example, wisdom is praised in a number of passages (iv 13, vii 5, 11, 12, 19, viii 1, ix 16, 17, x 2, 3), though it is elsewhere denounced as worthless. It may be said that the author, while denying that wisdom (practical sagacity and level headedness) can give permanent satisfaction, yet admits its practical value in the conduct of life. This

may be so, but it would be strange if a writer who could say "in much wisdom is much grief" should deliberately laud wisdom. It may be added that there are in the book a number of aphorisms about fools (v 3 [4], vii 5, 6, x 1-3, 12-15) quite in the style of the book of Proverbs, some of them contrasting the wise man and the fool, these appear to be the insertions of an editor. Further, it may be concluded with reasonable certainty that the passages that affirm a moral government of the world are additions by pious editors who wished to bring the book into harmony with the orthodox thought of the time.

Many practical admonitions and homely aphorisms are scattered through the book. iv 5, quiet is a blessing, iv 9-12, two are better than one, iv 17 (Eng v 1), be reverent in visiting the house of God (the temple and the connected buildings)—to listen (to the service of song or the reading of Scripture) is better than to offer a foolish (thoughtless) sacrifice, v 1 (2), be sparing of words in addressing God, v 1-5 (2-6), pay your vows—do not say to the priest's messenger that you made a mistake, vii 2-4, sorrow is better than mirth, vii 16-18, be not over-righteous (over-attentive to details of ritual and convention) or over-wicked (flagrantly neglectful of established beliefs and customs), here "righteous" and "wicked" appear to be technical terms designating two parties in the Jewish world of the 2nd and 1st centuries B.C., the observers and the non observers of the Jewish ritual law, these parties represent in a general way the Pharisees and the Sadducees, viii 2-4, x 20, it is well to obey kings and to be cautious in speaking about them, for there are talebearers everywhere, vii 20, no man is free from sin, vii 21, do not listen to all that you may overhear, lest you hear yourself ill spoken of, ix 4, a living dog is better than a dead lion, xi 2-6, show prudence, and decision in business, do not sell all your goods on one venture, act promptly and hope for the best.

Composition of the Book.—If the analysis given above is correct, the book is not a unit, it contains passages mutually contradictory and not harmonizable. Various attempts have been made to establish its unity. Other of the biblical Wisdom books (Job, Proverbs) are compilations—why not this? It is not necessary to multiply authors, as is done, for example, by Siegfried, who supposes four principal writers (a pessimistic philosopher, an Epicurean glossator, a sage who upholds the value of wisdom, and an orthodox editor) besides a number of annotators. Nor is it worth while to attempt a logical or symmetrical arrangement of the material.

A simple and adequate view of the growth of the book has been formulated by A. H. McNeile and followed by Barton. Its essence may be briefly stated. The original Koheleth, as has been indicated, was a very heretical work, nevertheless it was so brilliant and so in keeping with the mind of the Greek period that it obtained a firm hold upon the intelligence of the age. Orthodoxy, however, could not allow it to continue unchallenged or unopposed. Two sets of additions, therefore, were attached to it. One of them consists of a series of conventional aphorisms of the sages inserted to give the work a more Hebraic tone and colouring. Examples of this sort are seen in iv 5b, 6, vii 1-14. The second series is more positively and directly orthodox. It is in flat contradiction to the cold lifeless scepticism of Koheleth. It sets forth the traditional, positive and constructive view of life. It may be seen in such passages, for example, as iii 17, iv 17, xi 9d, xi 10, 13. Had it not been for the mollifying effect of such additions, it is hardly conceivable that Koheleth would ever have entered the Canon, or held its place there long if it had found entry.

Date.—As to the date of the book, there is a gradual approach to a consensus of opinion. The Solomonic authorship has long since been given up, the historical setting of the work and its atmosphere—the silent assumption of monotheism and monogamy, the non national tone, the attitude towards kings and people, the picture of a complicated social life, the strain of philosophic reflection—are wholly at variance with what is known of the 10th century B.C. and with the Hebrew literature down to the 5th or 4th century B.C. The introduction of Solomon, the ideal of wisdom, is a literary device of the later time and probably

derived nobody. The decision on considerations for the determination of the date in the language, the historical background and the thought. The language belongs to the post classical period of Hebrew. More than this there is much resemblance between the dialect of Kohleleth and that of the Mishna. Not only are new words employed, and old words in new significations, but the grammatical structure has a modern stamp—some phrases have the appearance of having been transcribed out of Aramaic into Hebrew. It is improbable that such Hebrew is that of Kohleleth would have been written earlier than the 2nd century B.C. (for details see Driver's *Introduction*). The general historical situation, also, presupposed or reflected to us that of the period from the year 200 B.C. to the beginning of our era, in particular the familiar references to kings is a part of the social system, and to social dislocations (servants and princes changing places, x 7), suggest the troublous times of the Hittor Greek and Maccabean rulers, of which the history of Josephus gives a good picture.

The conception of the world and of human life as controlled by natural law, a naturalistic cosmos, is alien not only to the prophetic and liturgical Hebrew literature but also to Hebrew thought in general. Whether borrowed or not, it must be late, and its resemblance to Greek ideas suggests Greek influence. The general air of Greek reflection seems unmistakable. The scepticism of Kohleleth differs from that of Job in quality and scope, it is deliberate and calm, not wrung out by personal suffering, and it relates to the whole course and constitution of nature, not merely to the injustice of fortune. Such a conception has a Greek tinge, and would be found in Jewish circles, probably, not before the 2nd century B.C.

A precise indication of date has been sought in certain supposed references or allusions to historical facts. The mention of persons who do not sacrifice or take oaths (ix 2) is held by some to point to the Essenes, if this be so, it is not chronologically precise, since we have not the means of determining the beginning of the movement of thought that issued in Essenism. So also the coincidences of thought with *Ben-Sira* (*Ecclesiastes*) are not decisive. *cf.* ix 14 with *BS* xvi 6, 2-6 (3-7) with *BS* xxxiv 1-7, vi 19 with *BS* xxxvii 14, x 8 with *BS* xxvii 26a, xi 10 with *BS* xxi 21, xi 10, 11 with *BS* xxxix 2 ff, xi 13 with *BS* xlii 27, if there be borrowing in these passages it is not clear on which side it lies, and it is not certain that there is borrowing—the thoughts may have been taken independently by the two authors. The conclusion that the book is of the 2nd century B.C. is based on the fact that the language and thought are of that period. The book is a mixture of prose and poetry, in about equal proportions. The fortunes of the book are not known in detail, but it is clear that its merciless criticism of life and its literary charm

made it popular, while its scepticism excited the apprehensions of pious conservatives. Possibly the *Wisdom of Solomon* (c. 50 B.C.) was written partly as a reply to it. The claim of sacredness made for it was warmly contested by some Jewish scholars. In spite of the relief afforded by orthodox additions, it was urged that its Epicurean sentiments contradicted the Torah and favoured heresy. Finally, by some process of reasoning not fully recorded, the difficulties were set aside, and the book was received into the sacred canon, but not until the synod of Jabneh in A.D. 90 was its right to remain in the canon officially and finally allowed. Jerome (on *Ecl.* xi 10, 14) declares that the decisive fact was the orthodox statement at the end of the book, the one important thing is to fear God and keep His commandments. It is not certain that it is quoted in the New Testament, but it appears to be included in Josephus' list of sacred books.

McNicoll, *Introduction to Ecclesiastes* (1904), G. A. Barton in the *Internal Crit.* Comm. (1908), M. Jastrow, *A Gentle Criticism* (1910), H. Rastson, *Ecclesiastes and the Early Greek Wisdom Literature* (1925). (C. H. T. J. M. P. S.)

ECCLIASTICAL COMMISSIONERS, in England, a body corporate, whose full title is "Ecclesiastical and Church Estates Commissioners for England," invested with very important powers, under the operation of which extensive changes have been made in the distribution of the revenues of the established church.

Their appointment was one of the results of the vigorous movements for the reform of public institutions which followed the Reform act of 1832. In 1835 two commissions were appointed "to consider the state of the several dioceses of England and Wales, with reference to the amount of their revenues and the more equal distribution of episcopal duties, and the prevention of the necessity of attaching by commendam to bishoprics certain benefices with cure of souls, and to consider also the state of the several cathedral and collegiate churches in England and Wales, with a view to the suggestion of such measures as might render them conducive to the efficiency of the established church, and to provide for the best mode of providing for the cure of souls, with special reference to the residence of the clergy on their

constituted a corporation with power to purchase and hold lands for the purposes of the act, notwithstanding the statutes of mortmain.

The first members of the commission were the two archbishops and three bishops, the lord chancellor and the principal officers of state, and three laymen named in the act.

The constitution of the commission was amended by the Ecclesiastical Commissioners acts, 1840-41, and 1868. The commission consists of the two archbishops, all the bishops, the deans of Canterbury, St. Paul's and Westminster, the lord chancellor, the lord president of the council, the first lord of the treasury, the chancellor of the exchequer, one of the principal secretaries of state, the lord chief justice, the master of the rolls, and certain lay members of the Church of England appointed by the crown and by the archbishop of Canterbury. The crown also appoints two lay members of the church estates commissioners and the archbishop of Canterbury one.

These three are the joint treasurers of the commission and form, with two members appointed by the commission, the church estate committee.

The substitution of one central corporation for the many local and independent corporations of the church so far at least as the management of property is concerned, was a constitutional

change of great importance, and the effect of it undoubtedly was to correct the anomalous distribution of ecclesiastical revenues by equalizing incomes and abolishing sinecures. At the same time it was regarded as having made a serious breach in the legal theory of ecclesiastical property.

"The important principle," said Clippes in *Law Relating to the Church and Clergy*, "on which the inviolability of the church establishment depends, that the church generally possesses no property as a corporation, or which is applicable to general purposes, but that such particular ecclesiastical corporation, whether aggregate or sole, has its property separate distinct and inalienable, according to the intention of the original endowment, was given up without an effort to defend it."

The commission presents an annual report to parliament in which full information is given as to its activities.

The main function of the commission is the management of the estates of the church in order to augment or endow benefices, etc.

ECCLESIASTICAL JURISDICTION The jurisdiction exercised by ecclesiastics, in taking cognizance of and deciding causes, over other ecclesiastics and over the laity. Before its union with the State, the power of the Church in this direction, as in others, was only spiritual. Coercive authority over their bodies or estates could only be given by concession from the secular power.

The fundamental principle of ecclesiastical jurisdiction with its "sanction" of excommunication will be found in the words attributed to Christ in Matt. xviii. 15-18. These injunctions indicate the customs of the Christian Churches at an early stage in their history. After the time of the Apostles, we find this criminal jurisdiction exercised by bishops individually over their respective "subjects"—doubtless with the advice of their presbyters according to the precept of St. Ignatius (*c.* 110). As neighbouring dioceses coalesced into "provinces" and provinces into larger districts (corresponding to the civil "dioceses" of the later Roman Empire), the provincial synods of bishops and the synods of the larger districts acquired a criminal jurisdiction, still purely spiritual, of their own. The theory, as expressed in legal phrase by Cyprian in the 3rd century, was that the apostolic power of delegated sovereignty from the Lord, alike legislative and judicial, was held in joint-tenancy by the whole body of Catholic bishops.

Even before the edict of Milan, at least as early as the latter half of the 3rd century, the spiritual sentences of deposition from office had sometimes indirect temporal consequences recognized by the secular courts. The classical example is the case of Paul of Samosata, bishop of Antioch. It would seem that, in the intervals of persecution, some rights of property were recognized in the Christian Church and its officers, although the Church was an illegal society. After some previous abortive trials, Paul of Samosata was deposed and excommunicated, in 269, by a great synod of the Antiochene district. Paul, notwithstanding his deposition, kept possession of the episcopal residence. The local church sought recovery of it before the tribunals of the Empire. The judicial authorities requested a rescript from the emperor Aurelian for the decision of the cause. Aurelian referred the matter to the bishop of Rome and the bishops of Italy, who gave their award in favour of the Antiochene Church.

Roman Empire from Constantine—With the "Nicene period" came a great development on the criminal side. A system begins to be formed, and the secular arm supports the decrees of the Church. The first trace of system is in the limited right of appeal given by the first oecumenical council of Nicaea and its provision that episcopal sentences or those of provincial synods on appeal were to be recognized throughout the world. Still examination must be had whether persons have been expelled from the congregation by any episcopal small-mindedness (*μικροψυχία*), or contentious spirit, or such-like harshness (*ἀνδρία*). That this may be conveniently inquired into, synods are to be held every year, in each province, and questions of this kind examined. And as regards the secular arm, the practice arose of superadding banishment by the emperor to synodical condemnation. The dogmatic

decrees of Nicaea I. were at once enforced in this manner. On the other hand, the Arian reaction it courted worked its objects by using the criminal spiritual jurisdiction of synods against the Catholics—often picking the synod to the purpose. The acts of councils of this age are full of the trials of bishops not only for heresy, but for immorality and common law crimes. The accusations are frequently unfounded, but the trials are already conducted in a certain regular forensic form. The secular authorities follow the precedent of Nicaea I. and intervene to supplement the spiritual sentence by administrative penalties. Sometimes an imperial officer of high rank is present at the synod, as an assessor to maintain order and advise upon points of procedure.

The trial of Athanasius shows a further stage in the development of ecclesiastical jurisdiction. Its significance is seen in the council of Sardica (347), a council of practically the whole West save Africa, which acquitted Athanasius after a full judicial inquiry. This council endeavoured to set up a system of appeals in the case of bishops, in which the see of Rome was made to play a great part. "Out of honour to the memory of St. Peter," a condemned bishop may ask the intervention of Rome. If the bishop of Rome thinks the cause should be heard again, he is to appoint judges, if otherwise, the original judgment is to be confirmed. Pending appeal, the appellant's see is not to be filled up.

The tendency to give pre-eminence to Rome appears again in an imperial letter to St. Flavian, who, in the judgment of the East, was bishop of Antioch, but who was rejected by the West and Egypt, summoning him to Rome to be there judged by the bishops of the imperial city—a summons which St. Flavian did not obey.

The story of the administrative development of the Church in the 5th century is mainly the story of the final emergence and constitution of the great "patriarchates," as authorities superior to metropolitans and provincial synods. In consequence of the occupants of the thrones of Constantinople and Alexandria falling successively into opposite heresies, the question arose how "patriarchs" were to be judged. In both cases, as it seems, an attempt was made by the bishop of Rome to depose the erring patriarch by his authority as primate of Christendom, acting in concert with a Western synod. In both cases, apparently, an oecumenical synod ignored the Roman deposition and judged the alleged offences of the respective patriarchs in first and last instance. The third and fourth oecumenical synods (Ephesus, 431, Chalcedon, 451) were primarily tribunals for the trials of Nestorius and Dioscorus; it was secondarily that they became organs of the universal episcopate for the definition of the faith, or legislative assemblies for the enactment of canon. Nothing is more remarkable than their minute care as to observance of rules of procedure. In both cases, imperial assessors were appointed. At Chalcedon, on the other hand, the imperial commissioners decided points of order, kept the synod to the question, took the votes and adjourned the court. The fifth oecumenical council came near to sitting in judgment over the pope. Vigilius, although in Constantinople, refused to attend the sittings of the council. He was cited three times, in the canonical manner, and upon not appearing was threatened in the third session with anathema (*Hefele, Councils*, §§ 263 ff.). After the council, Justinian banished the pope, until he accepted the council, which he ultimately did.

The constitution of the patriarchal system resulted in the recognition of a certain right of appeal to Rome from the larger part of the West. Britain remained outside that jurisdiction, the Celtic churches of the British islands, after those islands were abandoned by the Empire, pursuing a course of their own. In the East, Constantinople, from its pre-eminence, acquired special administrative pre-eminence, naturally followed, as in the case of Rome, by judicial pre-eminence. An example of this is found in the ninth canon of Chalcedon, which also illustrates the enforcement upon a clerical plaintiff in dispute with a brother cleric of recourse to the arbitration of their ecclesiastical superior. The canon provides that any cleric having a complaint against another cleric must not pass by his own bishop and turn to secular tribunals, but first lay bare his cause before him, so that by the sentence of the bishop himself the dispute may be settled by

arbitrators acceptable to both parties. In the next century Justinian put the other patriarchates on the same footing as Constantinople. But the growth of a special original jurisdiction at Constantinople, which perhaps developed earlier than the corresponding institution at Rome, may be traced to the fact that bishops from all parts were constantly in Constantinople. The bishop of Constantinople, even before he became properly "patriarch," would often assemble a synod from these visiting bishops, which acquired the technical name of *synodus evangelica*, the synod of sojourners. This synod frequently decided questions belonging to other patriarchates.

Theodosius I began the system of giving secular authority to Church tribunals. But it appears definitely in 475 when a constitution of Theodosius II provides that a recent decree of the usurper John should be disregarded and that clerk, whom he had brought before secular judges, should be reserved for the episcopal jurisdiction: "since it is not lawful to subject the ministers of the divine office to the arbitrament of temporal powers." Justinian has a clearer perception of the demarcation between the spheres of spiritual and temporal law. His system is based on the principle that if the offence be ecclesiastical, needing ecclesiastical correction the bishop shall take cognizance of it, but if a cleric be accused of a secular crime he shall be first accused before his bishop, who may depose him from his office and order, and then the competent judge may take him and deal with him according to the laws.

Certain enactments of later Saxon times in England have been sometimes spoken of as though they united together the temporal and spiritual jurisdictions into one mixed tribunal deriving its authority from the State. In the latter part of the 10th century, laws of Edgar provided that the bishop should be at the county court and also the alderman, and that there each of them should put in use both God's laws and the world's law (Johnson's *English Canons*, i. 411). This probably was, as Johnson suggests, that the bishop might enforce secular laws by ecclesiastical censure and the alderman ecclesiastical laws with secular punishment. But the two jurisdictions were kept separate, for by another law of Edgar it was provided that "in the most august assembly the bishop and alderman should be present, and the one should interpret to the people the law of God, the other the laws of men." In the meantime, however, on the Continent Charlemagne under the mistaken belief that he was following the authority of Constantine I and Theodosius I, had taken the serious step of empowering bishops to act as feudal judges, and causes could be taken from lay cognizance and transferred to the bishop's tribunal.

The Mediaeval System—With the latter 9th century we enter upon a new epoch, and by the time of Gregory VII, in the 11th century, the tribunals have fallen into the hands of a regular class of canonists who are in fact professional church lawyers in orders (see CANON LAW). The changes due to the adoption of the False Decretals by Nicholas I and the Application of their principles by Hildebrand (afterwards Gregory VII) are discussed elsewhere (see GREGORY VII, INVESTITURE, and kindred articles). The mediaeval system, thus inaugurated, may be considered (1) in its hierarchy, (2) in the subject matter of its jurisdiction, (3) in its penalties.

(1) It is a system of courts. Much that had been done by bishops is now done in the course of regular judicial procedure, the court takes the place of the synod, which ceases to have judicial work. The court of the metropolitan takes the place of the provincial synod, except possibly for the trial of bishops and even this becomes doubtful.

At first the bishop was the only judge in the diocesan court and he always remains a judge. But just as the king appoints judges to hear *placita coram rege* 1910, and the feudal lord appoints his seneschal or steward, so the bishop appoints his official, the "vicar-general" or "chancellor" (see CHANCELLOR). It was gradually established that as a king should not hear causes but commit them to his judges, so a bishop should not hear causes but appoint an official to hear them. In France the parlements were constantly insisting on the independence and irremovability of the official.

The ecclesiastical and secular courts are kept distinct. The charter of William the Conqueror abrogated the laws of Edgar. No bishop or archdeacon "shall any longer hold pleas in the Hundred concerning episcopal law nor draw a cause which concerns the rule of such to the judgment of men of the world" (Stubbs, *Select Charters*, part iii). In France, where the bishop was a temporal baron, his feudal and his spiritual courts were kept by distinct officers. From the bishop, or his official, appeal lay to the metropolitan, who again could hear causes by his official. The Constitutions of Clarendon recognize this appeal (c. viii). An appeal lay from the court of the metropolitan to that of the primate. There were many disputes as to the existence of these pumates (see Matland, *Canon Law in the Church of England*, p. 121). In England the dispute between Canterbury and York was settled by making them both primates giving Canterbury the further honour of being primate of all England. In France the primate sees and the course of appeals to them were well established.

In England the Constitutions of Clarendon added a provision for appeal to the king, "and if the archbishop shall have failed in doing justice recourse is to be had in the last resort (*postremo*) to our lord the king, that by his writ the controversy may be ended in the court of the archbishop, because there must be no further process without the assent of our lord the king." The last words were an attempt to limit further appeal to Rome. It will be observed that the king does not hear the cause or adjudicate upon it. He merely corrects slackness or lack of doing justice (*Si archiepiscopus defecerit in iustitia evadenda*) and by his writ (*precepto*) directs the controversy to be determined in the metropolitan court. As Bishop Stubbs says (*Report of Eccl. Comm. vol. i. Hist. App. 1*) "The appeal to the king is merely a provision for a rehearing before the archbishop, such failure to do justice being not so much applicable to an unfair decision as to the delays or refusal to proceed common at that time" (cf. Joyce, *The Sword and the Keys*, 2nd ed., pp. 19-20). The *recursus ad principem*, in some form or other of appeal or application to the sovereign or his lay judges, was at the end of the middle ages well known over western Europe. This recourse in England sometimes took the form of the appeal to the king given by the Constitutions of Clarendon, just mentioned, and later by the acts of Henry VIII, sometimes that of suing for writs of *prohibition* or *mandamus*, which were granted by the king's judges, either to restrain excess of jurisdiction, or to compel the spiritual judge to exercise jurisdiction in cases where it seemed to the temporal court that he was failing in his duty. The *appellatio tanquam ab abusu* (appel comme d'abus) in France was an application of a like nature.

Lastly there was the appeal to the patriarchs, &c. in the West to Rome. The distinguishing feature of this appeal was that the rule of the other appeals did not apply to it. In the regular course of those appeals an appellant could not leap the intermediate stages, but he could at any stage go to this final appeal, *omisso medio*, as it was technically called. Van Espen says "The whole right of appeal to the Roman pontiff *omisso medio* had undoubtedly its origin in this principle, that the Roman pontiff is ordinary of ordinaries, or, in other words, has immediate episcopal authority in all particular churches, and this principle had its own beginning from the False Decretals." There was an alleged original jurisdiction of the pope, which he exercised sometimes by permanent legates, whom Gregory VII and his successors established in the chief countries of Europe, and to whom were committed the legislative, executive and judicial powers of the spiritual "prince" in the districts assigned to them. After legates came special delegates appointed by the pope to hear a particular cause. It was the general practice to appoint two or three to sit together (Van Espen, *pars iii. tit. v. c. 37*). These might sub delegate the whole cause or any part of it as they pleased (*ibid.* 9-18). These courts were convenient since it was the custom to appoint delegates resident in the neighbourhood, and the power of sub delegation, general or limited, simplified questions of distance. In Belgium causes appealed to Rome had to be committed to local delegates (Van Espen, *pars iii. tit. v. c. 3, tit. x. c. 2*).

There could be an appeal from these delegates to the pope and from the pope himself to the pope "better informed" (Van Espen, pars iii tit v c 2, 13). So personal had the system of jurisdiction become that even the trials of bishops ceased to be necessarily conciliar. Generally they were referred to the pope (Van Espen, pars iii tit iii c 5, 17-19), but in England the archbishop, either in synod, or with some of his comprovincial bishops concurring, tried and deposed bishops (see case of Bishop Peacock and the other cases cited in *Read v Bishop of Lincoln*, 14 P D 148, and Phillimore, *EccL Law*, pp 66 et seq). The matrimonial cause between Henry VIII and Catharine of Aragon was the most famous English case tried by delegates under the "original" jurisdiction of the pope, and was ultimately "evoked" to Rome. The foreseen adverse termination of this long drawn cause led to Henry's legislation

When the temporal courts interfered to prevent excess of jurisdiction, they did so by prohibiting the ecclesiastical court from trying and the suitor from suing in that court. The pope could not be effectively prohibited, and no instance is recorded of a prohibition to papal delegates. But suitors have been prohibited from appealing to the pope (see per Willes, J., in *Mayor of London v Cox*, L.R. 2 H.L. 386). Whether, may have been the law, it is certain that, notwithstanding the statutes of Edw. III and Rich. II, appeals to Rome and original trials by papal delegates did go on, perhaps with the King's licence, for the statute 24 Hen. VIII c. 12 recites that the hearing of appeals was an usurpation by the pope and a grievous abuse, and proceeds to take away the appeal in matrimonial, testamentary and tithe causes, and to hinder, by forbidding citation and process from Rome, all original hearings also. The statute 25 Hen. VIII c. 19 follows this up by taking away appeals in all other subjects of ecclesiastical jurisdiction.

In 1438 the council of Basel took away all papal original jurisdiction (save in certain reserved cases), evocation of causes to Rome, appeals to Rome *omisso medio*, and appeals to Rome altogether in many causes. Such appeals when permissible, except the "greater," were to be tried by delegates on the spot (31st Session, Mansi, *Concilia*, in *loco*). These proceedings at Basel were regarded at Rome as of no effect. Nevertheless this decree and others were adopted by a French national council at Bourges and promulgated by the king as a "Pragmatic Sanction" (*gv*). The parlements registered the Sanction and the effect was permanent in France. Louis XI and Charles VIII sought to revoke it, but both parlements and states-general refused to recognize the revoking decrees. In 1490 Louis XII ordered the Pragmatic to be inviolably observed. The parlements thereupon condemned several private persons for obtaining bulls from Rome. In 1516 a Concordat between Leo X and Francis I settled all these questions in the sense of the Pragmatic, substantially according to the Basel canon. By this Concordat, by an ordinance of Francis I in 1539, by two or three other royal edicts, and (above all) by the practice of the parlements, explanatory of this legislation, and their *arrêts*, the conflict of secular and ecclesiastical jurisdictions was settled until the Revolution.

[illegible]

to the king in chancery. Thence a commission was to issue to persons named therein to determine the appeal definitely. Henry VIII exercised his jurisdiction as Supreme Head through a vicar-general. Edward VI exercised original jurisdiction in spiritual causes by delegated commissions (*see* Archdeacon Hile, *Precedents in Criminal Cases*, p. xlviii). Unless the king was to be regarded as an ecclesiastical person, they were not properly ecclesiastical courts, although spiritual persons might sit in them, for they sat only as royal commissioners. The same point has been taken by large bodies of clergy and laity in regard to the court of final appeal created by 25 Hen VIII c. 19 and its present successor, the judicial committee of Privy Council. At any rate the "original" jurisdiction claimed for the monarch personally and his delegates, under Henry VIII and Edward VI, has not permanently remained. In theory, Hooker's contentions have been conceded that "kings cannot in their own proper persons decide questions about matters of faith and Christian religion" and that "they have not ordinary spiritual power" (*Ecc Pol* viii 8, 1, 6, cf. xxxv Articles, Art. 37). In the case of an "established" church, and in particular, of the Church of England as by law established, Hooker's theory meets with important qualifications (*see* article ECCLESIASTICAL LAW).

The legal position of the clergy of the Church of England has been affected by a series of enactments of which the most important are the following: the "Church Discipline Act" (3 and 4 Vict c. 86) creating the "consistory court", the "Public Worship Regulation Act" (37 and 38 Vict c. 85), and the "Clergy Discipline Act" (55 and 56 Vict c. 32). The last remains of the old powers of ecclesiastical jurisdiction in reference to secular causes, have been removed during the 19th century. (1) All matrimonial, testamentary and *ab intestate* jurisdiction has been taken away by 20 & 21 Vict. c. 77 (testamentary, etc., England), c. 79 (testamentary, etc., Ireland), c. 85 (matrimonial, England), 33 & 34 Vict. c. 110 (matrimonial, Ireland). Matrimonial jurisdiction was taken from the bishop of Sodor and Man in 1884. (2) Since 6 & 7 Will IV c. 71, tithes have become, except in a few rare cases, tithes rent charge, and its recovery has been entirely an operation of secular law. Most kinds of offerings are now recoverable in secular courts. (3) Administration of pious gifts has passed to the court of chancery. (4) The enforcement of contractual promises has long been abandoned by the courts. Christian themselves. (5) Church rates can no longer be enforced by suit (35 & 36 Vict c. 109). (6) Disturbance was taken away in England by 18 & 19 Vict c. 41, and in Ireland by 23 & 24 Vict c. 32. (7) Laymen can no longer be tried in the spiritual courts for offences against clerics. (8) The jurisdiction of the bishop in church and state taken away by 23 & 24 Vict c. 31, in his civil capacity (*see* A. J. Stephens, *Feudal History*, vol. i, p. 136). On the other hand the "Church of England Assembly (Powers) Act, 1919," defined the powers of the Church in reference to internal affairs and facilitated Parliamentary action which this is required (*see* ENGLAND, CHURCH, 1).

The position of a disestablished or an unestablished church is comparatively modern, and has given rise to a number of complications. These Churches are *collegia laici* and come within the liberty of association so freely conceded in modern times. The relations of their bishops, priests or other ministers and lay office-bearers *inter se* and to their lay folk depend upon contract, and these contracts will be enforced by the ordinary courts of law. A consensual ecclesiastical jurisdiction is thus created, which has to this extent temporal sanction (*see* ECCLESIASTICAL LAW).

The case of Scotland presents special features. The church had the same jurisdiction in Scotland and exercised it through similar courts to those which she had in England and France, till about 1750. As late as 1566 Archbishop Hamilton of Glasgow, upon his appointment, had restitution of his jurisdiction by the prohibition of testaments and other matters (Keith, *History of the Scottish Bishops*, Edinburgh, 1824, p. 38). There was an interval of uncertainty with any rate of bishops till 1750. Then parliament enacted a new system of Church courts which, though to some extent in its turn superseded by the revival of episcopacy under James VI, was revived or ratified by the act of 1690, c. 7

and stands to this day. It is a Presbyterian system, and the Scottish Episcopal Church is a disestablished and voluntary body since 1690.

(*See* PRESBYTERIAN, SCOTLAND, CHURCH OF.)

Protestant Continental European States.—With the Reformation in the 16th century, Church courts properly speaking disappeared from the non-episcopal religious communities which were established in Holland, in the Protestant states of Switzerland and of Germany, and in the then non-episcopal countries of Denmark and Norway.

Discipline over ministers and other office bearers was exercised by administrative methods in the form of trials before consistory or synods. To this extent ecclesiastical jurisdiction is still exercised in these countries. Consistories and synods have exercised discipline of a penitential kind over their lay members, but in later times their censures have generally ceased to carry temporal consequences. Ecclesiastical jurisdiction on the civil side for the trial of causes soon disappeared.

The matter is now determined for all countries which have adopted codes, whether after the pattern of the Code Napoléon or otherwise. These countries have created a hierarchy of temporal courts competent to deal with every matter of which law takes cognizance, and a penal code which embraces and deals with all crimes or delicts which the state recognizes as offences. Hence, even in countries where the Roman Church is established, such as Belgium and Italy, the most of the Latin republics of America, and the province of Quebec, and a *fortiori* where this Church is not established, there is now no discipline over the laity, except penitential, and no jurisdiction exercised in civil suits, except possibly the matrimonial questions of princes (of which there was an example in the case of the late prince of Monaco). In Spain causes of nullity and divorce *a thoro*, in Portugal causes of nullity between Catholics are still for the court Christian (non-secular).

BYZANTINISM.—The subject of ecclesiastical jurisdiction in modern times inevitably links itself onto the ecclesiastical and civil history of the countries concerned. On the general subject, *see* ECCLESIASTICAL LAW, and, for further references, articles "Law, Christian" in *Hastings' Encyclopedia of Religion and Ethics*, vol. viii, "Roman Catholic" and "Eastern" by Adrian Fortescue, and "Anglican" by A. J. Maclean. For the history of the principal codes *see* Canon Law. On the development of ecclesiastical jurisdiction in the Church of Rome *see* ROMAN CATHOLIC CHURCH, and (from other points of view) TRENT, COUNCIL OF, VATICAN COUNCIL, and ULTRAMONTANISM. With reference to the Eastern church, *see* ORTHODOX EASTERN CHURCH, also Landon, *Manual of Councils* (1893), s.v. "Constantinople" and "Rome"; Mouravieff, *History of the Russian Church*, Eng. tr. 1842; Hackett, *Orthodox Church in Cyprus* (1901); Milasch, *Das Kirchenrecht der morgenländischen Kirche* (1905). With reference to the Anglican Church, *see* Blunt, Phillimore and Jones, *Book of Church Law*, 1899; W. E. Collins *Nature and Force of the Canon Law* (Church Historical Society, no. xxvii, 1908), and the classical statement of Hooker, *Ecclesiastical Polity*, bk. viii. With reference to the middle ages, *see* the relative parts of the *Cambridge Mediaeval History* and the classical works of van Espen (Louvain, 1720) *Jus ecclesiasticum universum, Observationes in Concilio Lateranense vi, De recurso ad Principem*. *See* also other works mentioned in the course of the foregoing article (X).

ECCLESIASTICAL LAW, in its broadest sense, the sum of the authoritative rules governing the Christian Church, whether in its internal polity or in its relations with the secular power. Since there are various churches, widely differing both in their principles and practice, it follows that a like difference exists in their ecclesiastical law, which is the outcome of their corporate consciousness as modified by their special relations to the secular authority. At the outset, a distinction must be made between those which are established and those that are "free." The ecclesiastical laws of the latter are, like the rules of a private society or club, the concern of the members of the church only, and come under the purview of the State only in so far as they come in conflict with the secular law (*see*, *polity* among the "Morris" or violation of the trust deeds under which the property of a church is held). In the case of "established" churches, on the other hand, wherever the principle on which the system is based or the doctrine in its practical application, the essential conditions are that the ecclesiastical law is also the law of the land, the decisions of the church courts being enforced by the

civil power. This holds good both of the Roman Catholic church, wherever this is recognized as the "State religion," of the Oriental churches whether closely identified with the State itself, or endowed with powers over particular nationalities within the State, and of the various Protestant churches established in Great Britain and on the Continent of Europe.

Writers on the theory of ecclesiastical law, moreover, draw a fundamental distinction between that of the church of Rome and that of the Protestant national or territorial churches. This distinction is due to the claim of the Roman Catholic church to be the *only* church, her laws being thus of universal obligation, whereas the laws of the various established Protestant churches are valid—at least so far as legal obligation is concerned—only within the limits of the countries in which they are established. The practical effects of this distinction have been, and still are, of enormous importance. The Roman Catholic church, even when recognized as the State religion, is nowhere "established" in the sense of being identified with the State, but is rather an *imperium in imperio* which negotiates on equal terms with the State, the results being embodied in concordats (*q.v.*) between the State and the pope as head of the church. The concordats are of the nature of truces in the perennial conflict between the spiritual and secular powers, and imply in principle no surrender of the claims of the one to those of the other.

Protestant ecclesiastical law, then, is distinguished from that of the Roman Catholic church (1) by being more limited in its scope, (2) by having for its authoritative source, not the church only or even mainly, but the church in more or less complete union with or subordination to the State, the latter being considered, equally with the church, as an organ of the will of God. The ecclesiastical law of the church of Rome, on the other hand, what ever its origin, is now valid only in so far as it has the sanction of the authority of the Holy See. And it must be noted that the "canon law" in its old sense is not identical with the "ecclesiastical law" of the Roman Catholic church. By the canon law used to be meant the contents of the *Corpus iuris canonici*, which have been largely superseded or added to by, e.g., the canons of the Council of Trent and the Vatican decrees. The long projected codification of the whole of the ecclesiastical law of the church of Rome, was completed in 1917 in the form of the *Code of Canon Law* (1917).

The ecclesiastical law of the church of Rome, as it is now, is a complex of laws, customs, and decrees, which have been largely superseded or added to by, e.g., the canons of the Council of Trent and the Vatican decrees. The long projected codification of the whole of the ecclesiastical law of the church of Rome, was completed in 1917 in the form of the *Code of Canon Law* (1917).

by parliament in the ordinary course of legislation, and in point of fact a very large portion of the existing ecclesiastical law consists of acts of parliament.

The first principle of the ecclesiastical law in England is the assertion of the supremacy of the Crown, which in the present state of the constitution means the same thing as the supremacy of parliament. This principle has been maintained ever since the Reformation. Before the Reformation the ecclesiastical supremacy of the pope was recognized, with certain limitations, in England, and the church itself had some pretensions to ecclesiastical freedom. The freedom of the church is, in fact, one of the standing provisions of those charters on which the English constitution was based. The first provision of Magna Carta is *quod ecclesia Anglicana libera sit*. By the various enactments of the period of the Reformation the whole constitutional position of the church, not merely with reference to the pope but with reference to the State, was definitely fixed. The legislative power of

convocation was held to extend to the clergy only, and even to that extent required the sanction and assent of the Crown. The common law courts controlled the jurisdiction of the ecclesiastical courts, claiming to have "the expungition of such statutes or acts of parliament is concern either the extent of the jurisdiction of these courts or the matters depending before them. And therefore if these courts, either refuse to allow these acts of parliament, or expound them in any other sense than is truly and properly the exposition of them, the king's great courts of common law may prohibit and control them."

The design of constructing a code of ecclesiastical laws was entertained during the period of the Reformation but never carried into effect. It is alluded to in various statutes of the reign of Henry VIII, who obtained power to appoint a commission to examine the old ecclesiastical laws, with a view of deciding which ought to be kept and which ought to be abolished, and in the meantime it was enacted that "such canons, institutions, ordinances, synodals or provincial, or other ecclesiastical laws or jurisdictions spiritual as be yet accustomed and used here in the church of England, which necessarily and conveniently are requisite to be put in use and execution for the time, not being repugnant, contrariant, or derogatory to the laws or statutes of the realm, nor to the prerogatives of the royal crown of the same, or any of them, shall be occupied, exercised, and put in use for the time with this realm" (25 Henry VIII c. 19, 35 c. 16).

The work was actually undertaken and finished in the reign of Edward VI by a subcommittee of eight persons, under the name of the *Reformatio legum ecclesiasticarum*, which, however, never obtained the royal assent. Although the powers of the 25 Henry VIII c. 19, were revived by the 1 Elizabeth c. 1, the scheme was never executed, and the ecclesiastical laws remained on the footing assigned to them in that statute—so much of the old ecclesiastical laws might be used as had been actually in use, and was not repugnant to the laws of the realm.

The statement is, indeed, made by Sir R. Phillimore (*Ecclesiastical Law*, 2nd ed., 1895) that the "Church of England has at all times, before and since the Reformation, claimed the right of an independent church in an independent kingdom, to be governed by the laws which she has deemed it expedient to adopt." This position can only be accepted if it is confined, as the authorities cited for it are confined, to the resistance of interference from abroad. If it mean that the church, as distinguished from the kingdom, has claimed to be governed by laws of her own making, all that can be said is that the claim has been singularly unsuccessful. From the time of the Reformation no change has been made in the law of the church which has not been made by the king and parliament, sometimes indirectly, as by confirming the resolutions of convocation, but for the most part by statute. The list of statutes cited in Sir R. Phillimore's *Ecclesiastical Law* fills 11 pages. It is only by a kind of legal fiction that the church can be said to have deemed it expedient to adopt these laws.

The terms on which the church establishment of Ireland was abolished, by the Irish Church Act of 1869, may be mentioned. By s. 20 the present ecclesiastical law was made binding on the members for the time being of the church, "as if they had mutually contracted and agreed to abide by and observe the same," and by s. 21 it was enacted that the ecclesiastical courts should cease after Jan. 1, 1871, and that the ecclesiastical laws of Ireland, except so far as relates to matrimonial causes and matters, should cease to exist as law. (See also ENGLAND, THE CHURCH OF.)

BIBLIOGRAPHY.—The number of works on ecclesiastical law is very great, and it must suffice here to mention a few of the more conspicuous modern ones. Ferdinand Walter, *Lehrbuch des Kirchenrechts aller christlichen Konfessionen* (14th ed., Bonn, 1871), G. Phillips, *Kirchenrecht*, Bde 1-10 (Regensburg, 1845-72), incomplete, the text-book by Cardinal Hergenrother (*q.v.*), P. Hinschius, *Kirchenrecht der Katholiken und Protestanten in Deutschland*, 6 Bde (1869 sqq.), only the Catholic part, a masterly and detailed survey of the ecclesiastical law, finished, Sir Robert Phillimore, *Ecc. Law of the Church of England* (2nd ed., ed. by Sir Walter Phillimore, 1895). For further references see CANON LAW, and the article "Kirchenrecht" in Herzog-Hauck, *Realencyklopädie* (ed. Leipzig, 1901), C. F. S. Zollman, *Amer. Civil Church Law* (1917), P. Gillet, *La personnalité juridique en droit ecclésiastique* (Malines, 1927).

berctum (ed. Plummer, 1896), *Chronicle*, sub ann. 734, 735, 738, 766 (ed. Earle and Plummer, 1899), Hadden and Stubbs, *Councils and Ecclesiastical Documents* (1869-78), II, 403-431, *Proceedings of Surtees Society* (Dulham, 1853).

ECGBERT or **ECGBERTH** (d. 839), king of the West Saxons, son of Ealhmund, succeeded to the throne in 802 on the death of Beorhtic. It is said that at an earlier period in his life he had been driven out for three years by Offa and Beorhtic. In 815 Ecgbert ravaged the whole of the territories of the West Welsh, which probably at this time did not include much more than Cornwall. In 825 he joined the men of Devon against the West Welsh, who were again defeated at Camelford. The next important occurrence in the reign was the defeat of Beornwulf of Mercia at Ellendun, probably near Winchester, in 825. Ecgbert sent his son Aethelwulf against Kent, he drove Baldred, king of Kent, across the Thames, and Kent, Surrey, Sussex and Essex submitted to Wessex, while the East Angles, who slew Beornwulf shortly afterwards, acknowledged Ecgbert as overlord. In 829 the king finally conquered Mercia, and Northumbria, which accepted him as overlord. Ecgbert was the first king to hold the whole of England under his overlordship. He also increased his power by reversing the Mercian policy of resisting the authority of the archbishops, and by making an agreement of perpetual alliance with the church of Canterbury. In 830 he led a successful expedition against the Welsh. In 836 he was defeated by the Danes, but in 838 he entirely routed them and their allies the West Welsh at Hingston Down (Hengist dune) in Cornwall. Ecgbert died in 839, after a reign of 37 years, and was succeeded by his son Aethelwulf.

See *Anglo-Saxon Chronicle* (ed. Earle and Plummer, 1899), W. de G. Birch, *Cartularium Saxonicum* (1885-93). Also a paper by Sir H. H. Howorth in *Numismatic Chronicle*, 3rd series, vol. xx pp. 66-87 (reprinted separately, 1900), where attention is called to the peculiar dating of several of Ecgbert's charters, and the view is put forward that he remained abroad considerably later than the date given by the *Chronicle* for his accession. On the other hand a charter in Birch, *Cart Sax.*, purporting to date from 799, contains the curious statement that peace was made between Coenwulf and Ecgbert in that year.

ECGONINE, a white crystalline alkaloid of the tropane group, is chiefly of interest because of its relation to cocaine. Ecgonine is a tropane carboxylic acid $C_{15}H_{21}NO_3$, and cocaine is its benzoyl methyl ester.

l-Ecgonine results from the alkaline hydrolysis of *l*-cocaine (the naturally occurring form), it melts at 205°C when anhydrous α -Ecgonine is an isomeride, having its CO_2H group attached to the same carbon atom as the OH group.

ECHEGARAY Y EIZAGUIRRE, JOSÉ (1832-1916), Spanish mathematician, statesman and dramatist, passed out at the head of the list of engineers in the Escuela de Caminos at Madrid, and, after a brief practical experience at Almería and Granada, was appointed professor of pure and applied mathematics in the school where he had lately been a pupil. Between 1867 and 1874 he acted as minister of education and of finance, upon the restoration of the Bourbon dynasty he withdrew from politics and under the pseudonym of Jorge Hayaseca won a new reputation as a dramatist with *El Libro talarario*, which was played at the Teatro de Apolo on Feb. 18, 1874. Later in the same year Echeagaray achieved a popular triumph with *La Esposa del vengador*, in which the good and bad qualities—the clever stagecraft and unbridled extravagance—of his later work are clearly noticeable. From 1874 onwards he wrote, with varying success, a prodigious number of plays. Among the most favourable specimens of his talent may be mentioned *En el puño de la espada* (1875), *O locura o santidad* (1877) and *En el seno de la muerte* (1879). *El gran Galeoto* (1881), perhaps the best of Echeagaray's plays in conception and execution, has been translated into several languages. The humorous proverb, *¿Pues*

mal y acertaras? exemplifies the author's limitations, but the attempt is interesting as an instance of ambitious versatility. His susceptibility to new ideas is illustrated in such pieces as *Moruna* (1892), *Mancha que limp* (1895), *El Hijo de Don Juan* (1892), and *El Loco Dios* (1900), these indicate a close study of Ibsen, and *El Loco Dios* more especially might be taken for an unintentional parody of Ibsen's symbolism.

Echeagaray enjoyed exceptional popularity for over 30 years, but his vogue is now over. He had valuable gifts in a ritual construction, in the arrangement of dramatic scenes, in mere theatrical technique, in the focusing of attention on his chief personages, few writers excel him. He had, moreover, a powerful, gloomy imagination, which is momentarily impressive. But in the drawing of character, in the invention of felicitous phrase, in the contrivance of verbal music, he is deficient. He alternates between the use of verse and prose, and his hesitancy in choosing a medium of expression is amply justified, for the writer's prose is not more distinguished than his verse.

See L. Anton del Olmet and A. García Canalis, *Echeagaray* (1912). **ECHOLON**, in military tactics and drill, a formation of troops composed of successive and parallel units facing in the same direction, each on a flank, and to the rear of, the unit in front of it (Fr. from échelle, ladder). The disposition of the whole thus resembles the steps of a staircase. To form echelon from line, the units forming the line move off, each direct to its front, in succession, so that when the formation is completed the rightmost body, for example, is farthest advanced, the one originally next on its left is to the left rear, a third is to the left rear of the second, and so on. The word is also used more loosely in tactics and strategy to express the successive parts of a unit or force, e.g. forward, reserve or rear echelon, irrespective of distances and relative positions, and in military organization to indicate parts of the headquarters organization which are left in rear of the fighting zone.

ECHIDNA or **SPINY ANTEATER** (*Tachyglossus*), one of the Monotremata (*q.v.*) the lowest subclass of Mammalia. It is a native of Australia, burrowing in sand, or hiding in rock crevices. In size and appearance it resembles a hedgehog, its upper surface being covered over with strong spines directed backwards and inwards, so as to cross each other on the middle line. The tail is very small. It has a long tubular snout with a small mouth, its tongue is long and slender, lubricated with a viscous secretion, by means of which it seizes the insects on which it feeds. It has no teeth. Its legs are short and strong and form powerful burrowing organs. The male echidna has its heel provided with a sharp hollow spur, connected with a gland. It is a nocturnal animal. When attacked it seeks to escape either by rolling itself into a ball or by burrowing rapidly into the sand. Two eggs are laid and these are carried, as are the young at an early stage, in an abdominal pouch, into which open the mammary glands. The echidnas are restless in confinement and constantly endeavour to effect their escape by burrowing. There are two varieties: the Port Moresby echidna of southeastern New Guinea with longer beak and shorter spines, and the hairy echidna of Tasmania. In all, the spines are mixed with hair, in the Tasmanian race they are nearly hidden by the long harsh fur. Of the curved-beaked echidnas (*Zaglossus*) confined to New Guinea there are several races, about 30 in all in length.

ECHINODERMA (Echinoderms), a group of animals that live in the sea and constitute one of the great branches (phyla) of the animal kingdom. Familiar examples are the sea-urchin (Echinoid), the sea-star or starfish (Asteroid) and the brittle-star (Ophiuroid). Less familiar are the feather star and sea lily (unstalked and stalked Crinoid), and the sea-cucumber (Holothurian) (figs. 1-5). These forms represent the five classes into which the Echinoderms now living are usually divided. In the older periods of the world's history there were other classes, none of which have survived.

The living forms are of such diverse appearance, and for the most part so unfamiliar, that there is no vernacular English name for the group. "Echinoderma" is a Greek word and means "prickle-skinned" ("animals" being understood). The Greeks gave

the name "Echinus" to two animals of very different nature, but both protected by a coat of prickles: one the hedgehog or urchin of the Ind, the other the sea urchin, which the French call *oursin*. Both urchin and *oursin* are connected with the French *herisson*, to bristle. The name *Echinus* has been continued in use for a kind of sea urchin. The name "Echinodermata," often applied to the whole branch means "sea urchin skins," and was

FIG 1—SEA STAR OR ASTEROID

invented in 1734 by J. T. Klein to denote only the empty shells or tests of sea urchins.

CHARACTERS AND RELATIONS

Diverse though living echinoderms are, all possess certain characters, some of which they hold in common with other types of animals, while others are distinctive of the group. The common characters may be mentioned briefly. The substance of an echinoderm is built of many cells, the animals are multicellular (Metazoa, as opposed to Protozoa). An echinoderm differs from

FROM "THE CAMBRIDGE NATURAL HISTORY" (BRITANNICA)

FIG 2—BRITTLE STAR OR OPHIUROID

such animals as sea anemones and jelly-fish, which are little more than sacs (Coelentera=hollow guts), in having the inside of the sac divided into a gut or digestive tube and a body-cavity or coelom (=hollow), in this it resembles molluscs, annelids, arthropods and vertebrates. Such animals are called Coelomata. The fundamental plan of an echinoderm, as in all Coelomata, is bilateral, and any appearance of radial symmetry is secondary

Radial Arrangement—Living echinoderms are distinguished from the other Coelomata by the following characters—All show a division of most of the body structures into five sectors, commonly produced as rays or "arms." These rays may branch, may increase in number, or may be partly suppressed, but the number five is fundamental. The middle line of each ray is termed a radius, a line drawn midway between two adjoining radii is termed an interradius. Thus the body surface may be

FROM "BOTANICAL HISTORY" BY PERMISSION OF F. WARNE & CO

FIG 3—SEA URCHIN OR ECHINOID

mapped into five radial areas alternating with five interradial areas. In living echinoderms the organs that show the radial arrangement most clearly are numerous sacs, canals and tubes which carry water through the body and constitute a hydraulic apparatus (water-vascular system). In its most typical form

FIG 4—FEATHER STAR OR UNSTALKED CRINOID

(fig 6) this consists of a ring canal round the mouth, indirectly connected with the water outside, and sending a canal down each of the radii. From each side of this radial water-vessel small branches are given off, and their ends project from the surface of the animal as closed tubes with muscular walls, since

FIG 5—SEA CUCUMBER OR HOLOTHURIAN

in the second class they are called "tentacles" or "tentacles." The part is the wind-up of the tube or the tentacles look like those of a sea cucumber. The "tentacles" hence that radial area or the test is called an ambulacrum, and the interradial areas are called interambulacra.

In the older and more primitive classes of Echinodermata, the hydraulic ambulacral system did not subserve locomotion, but only sensation and respiration. The five-rayed structure did not originate in this system, but was due to the extension from the

mouth of five grooves lined with minute lashes (cilia), which by constant whipping drive a stream of water with food particles towards the mouth. The food collecting area was increased by the elongation or branching of the grooves, as in crinoids and sea stars, and the water-vessels followed the food grooves. In crinoids and sea stars the food grooves are open and in use, but in brittle stars, sea-urchins, and holothurians they have become

mans of molluscs, corals, arthropods and other animals. Other Common Characters.—The following characters of less obvious nature are also common to all living echinoderms.—The egg develops first into an elongate, two sided larva (figs 21 and 22), with an uncoiled gut, and with the body cavity essentially arising as three pairs of pouches (coeloms), all or part

FROM MONTENEGRO. PIONIERE. SAHARA'S FAUNA (G. C. 535)

FIG 6—HYDRAULIC APPARATUS OF SEA STAR

closed over, while the ambulacral system continues to send out its podia (fig 7)

Spicular Structure of Skin—The name Echinodermata expresses one of the chief characters of the branch. Prickles, it is true, are not so extensively developed in the other classes as they are in sea-urchins, though they are present in considerable numbers in most of them. The essential feature is the presence in the deeper layers of the skin of minute spicules of crystalline carbonate of lime (calcite), which usually grow together into plates, or small bones, or prickles, all so interpenetrated with the connecting fibres of the body wall that they constitute a beam and rafter work (fig 8). Under the microscope a thin section of this looks like a net. Wherever the mid layer or mesoderm occurs in the body, and not only in the body-wall, its cells have this power of depositing lime, they can also reabsorb it and redeposit it, so that the shape and structure of the skeleton change as the animal grows. In all these respects the skeletal tissue of Echinodermata is paralleled only by the bone of Vertebrata, but it differs from

FROM LANKESTER. TREATISE ON ZOOLOGY (A B C BLACK)

FIG 8—SKELETAL SUBSTANCE OF ECHINODERMA

of this is somewhat abruptly changed into a radial creature with coiled gut. This characteristic metamorphosis is described later. The nervous systems are three: (1) the outer oral sensory system, chiefly composed of a ring round the mouth, and radial nerves lying outside the water vessels, and derived from the superficial epithelium, (2) the deeper oral motor system, lying just below the former, supplying the muscles in the oral side of the body wall, (3) the apical motor system, most highly developed in crinoids, its centre is where the stem originates, and its cords pass down the stem and the rays to work their muscles, it is in all classes except holothurians. The blood system consists of a number of spaces rather than definite vessels, without heart or regular circulation, its contents differ from the general fluid of the body-cavity only in containing more albumen. In all the internal fluids float various bodies some are red with haemoglobin (like human blood corpuscles) and aid respiration, others are white, wandering, amoebalike cells, which serve many purposes, some eating the various waste products and then squeezing their way to the exterior, for there is no definite excretory system.

Relationships—The Echinodermata as we have seen, differ from other radial animals, but agree with many other branches, in the separation of a body cavity (coelom) from the primitive hollow, which persists as the gut. The various branches of the

FIG 7—CROSS SECTIONS OF RADIAL GROOVE

bone in chemical composition, in the formation of the spicules within the cells and not outside them, and in the retention of a crystalline character so that each plate acts as an individual crystal. By the cleaved surface characteristic of calcite and the netlike appearance, even minute fragments of echinoderm skeleton embedded in the rocks can be distinguished from the

FROM LANKESTER. TREATISE ON ZOOLOGY (A B C BLACK)

FIG 9—SIMPLIFIED DIAGRAM OF THE DIPLEURULA

Coelomata may have sprung independently from the Coelentera, and if there was any connection between them it must have been through forms whose existence we can only infer from a study of the oldest fossils and of the earliest stages in the life history of their living descendants. Thus we find the mode of origin of the coelom and its early division into three pairs of sacs paralleled only in that great branch of the Coelomata which includes all animals with a backbone or with its cartilaginous precursor termed "notochord." The lower Chordata (as the branch is named) comprise the lancelet (*Amphioxus*), the sea-squirts or

ascidians, and some less known, often worm shaped creatures named Enteropneusta. All (Chordata, except sea squirts, show traces of this triple division of the coelom, and the growth of its middle division into lobes and tentacles is seen also in some Enteropneusta. The larva of one of the Enteropneusta (*Balanus glossus*) was originally described as an independent animal (*Tornaria*) and supposed to be related to the Echinoderm larval forms—the presence of a wider pore accentuates the outer similarity. The mouth of the developing cladonidium, when it shifts from the original median position, invariably moves to the left not to the right, in the hinged mouth opens up first on the left side. The central nervous system of Chordata, like the other nervous system of Echinoderm is derived from the outer epidermis and sinks below the surface in the same manner, this indicates that the ancestral forms responded to certain outer stimuli by a similar mechanism. The resemblances and differences between echinodermal and vertebrate skeletal tissue have already been emphasized. All these facts suggest that the Echinoderm and the Chordata were derived from a common ancestor, differing from the ancestors of other Coelomata, but itself not yet either an echinoderm or a chordate.

CLASSIFICATION

The five classes into which, as said at the outset, Echinoderm now living are usually divided, are not of equal value, for the Asteroidea and Ophiuroidea diverged in a comparatively late geological period, so that the differences between them are not so profound as those that distinguish the other classes, the difficulty is met by merging them in a super class, Stelliformia. In early Palaeozoic times there existed other classes, all of which became extinct before the Mesozoic era began. Most of these creatures resembled most crinoids in being attached to the sea floor and in feeding on minute organisms, which they swept along chitinous grooves into their usually upturned mouths. They have therefore been grouped with the crinoids as Palaeozoic (stalk animals), while the remaining classes, which are free moving and generally feed with down turned mouth on larger organisms have been opposed to them under the name Eleutherozoa (free animals). These names conveniently connote definite facts of structure and habit, but do not imply any closer relationship between the classes included under them. The classification here adopted embodies a few recent advances. Certain Palaeozoic, that, in editions of the *Encyclopaedia Britannica* after 1900, have been placed under Cystoidea as an order Carpoidea are now distinguished as a class. On the other hand the Blastoidea, though numerous and rather sharply defined, are a relatively late offshoot from the Cystoidea, and it they are retained here as a class, it is only because authorities disagree upon their point of origin. W. J. Sollas has proposed a class Ophiocystis for a few rare Silurian fossils, of which the structure was long misunderstood though correctly given in the *Encyclopaedia Britannica* (1911), they may be modified Stelliformia or Echinoderm but cannot be maintained as a separate class. Recently some Palaeozoic fossils, usually regarded as Cirripedia, have been identified by T. H. Withers (1926) to the Echinoderm, and F. A. Bather has accepted that view, while keeping them apart as a sub-branch, Machaeridia. The larger divisions of the Echinoderm here accepted may be tabulated, without implication as to their mutual affinity, thus—

- With no trace of Radial structure
 - † Machaeridia
 - † Carpoidea
- With more or less Radial structure
 - † Cystoidea
 - † Blastoidea
 - † Cystoidea
 - † Echinosteroidea

Asteroidea } Stelliformia } Eleutherozoa
 Ophiuroidea }
 Echinoderm }
 Holothuroidea }
 The † denotes that the group became extinct before the Mesozoic.

COMPARATIVE ANATOMY AND PHYSIOLOGY

Machaeridia—Of the Machaeridia only one skeleton is known, and it is mainly because its plates have shown the crystalline cleavage characteristic of echinoderms that they have been placed in this branch. In the simpler forms the plates are in two rows, hinged down the back, and opening on the other side (fig. 10), scars on their inner face indicate the presence of muscles that would pull the two sides together. One infers that the animal was elongate, flexible, symmetrically two sided, with a mouth and some sensory organ at the fore end, and a vent at or near the hind end, it may have been such a creature as study of recent larvae has led several authors to imagine as a probable ancestor under the name *Dipleuralia* (little two-sided) (fig. 9). In that the two front pairs of coeloms would have opened to the exterior by a pore apiece, but no trace of such a pore has yet been seen in machaeridian plates. More advanced forms had four rows of plates, two on each side. At one end a plate was often modified in a way that suggests temporary fixation.

Carpoidea—All Carpoidea bear traces of a stem by which the body was attached to some object on or near the sea-floor (fig. 11). In most the skeleton shows some two sided symmetry, if only in a part of the stem, this may have originated in the symmetry of the *Dipleuralia*, but its gradual increase in various series of the class is due to adaptation. Nearly all Carpoidea are flattened in a plane parallel to the sea-floor, and either the whole body-wall is flexible or one side remains flexible, so that it could expand and contract as the animal drew in or expelled water for food or aeration. The positions of intake and vent relative to the stem and to each other vary according to the particular habitat and mode of life of each genus, originally, perhaps, they were at

BY COURTESY OF THE ROYAL SOCIETY OF EDINBURGH FROM BATHER CARPOIDEA CYSTOIDEA DENTROCYSTIS

FIG. 12—THE SYMMETRIES OF THE CHIEF CLASSES

opposite ends of the body and the stem arose between them, in any case the arrangement differed from that of all other Palaeozoic. In the apparent absence of water-pore, genital pore and any trace of radial symmetry, the Carpoidea and Machaeridia differ from all other classes.

Cystoidea—The Cystoidea, like all other echinoderms, have a

two sided symmetry, but in them we see the rise of radial symmetry. Study of this enables one to draw a plan by which the symmetries in other classes can be compared (fig 12). Normally the cystoids are attached to the sea floor by one pole of the body and take in food through a mouth at the opposite, upper pole. Near the mouth is a water pore, and close to it, but further from the mouth, is a genital pore, the vent is usually in the same line,

AFTER JAECKEL IN STAMMERDRECHTIGHEIT DER
PELMATOZOEN (JULIUS SPRINGER, BERLIN)
FIG 13—A RHOMBIFEROUS CYSTOID
CHIROCRINUS NAT SIZE

at the side of the body. Thus the body can be divided into similar halves by a plane passing through the mouth or oral pole, the apical hole, and the water pore. This plane is termed the *M* plane (because in other classes the water pore is broken up into many, and the perforated plate is called a *madreporite*) and it can always be identified. The rays originate by the extension of the ciliated lining of the gullet over the body-surface, it stretches out in the form of grooves, the first, naturally, away from the vent, towards the front or anterior part of the body, the second and third towards the free space on each side, later, these three grooves become five by the forking of the right and left grooves. The food-collecting surface was usually increased by the extension of the grooves on little jointed appendages (brachioles), which did not contain prolongations of the body cavity or of the generative system (fig 13). The water system may have sent branches through the mouth opening along the food grooves, but did not subservise locomotion. Aeration of the body-fluids was effected through thinner portions of the test, and according to the structure of these the Cystoidea may be grouped in two subclasses—(1) Rhombifera or Dichopora, in which the breathing organs are folds of the test-wall, crossing the sutures of the plates (fig 13), (2) Diploporita, in which the breathing organs are canals of U-shape within the test wall and not crossing the sutures (fig 14). There are other differences between these subclasses.

Blastoidea.—The Blastoidea proper (fig 15) have a body-skeleton of 13 main plates arranged in three circlets, according to a marked five rayed symmetry, viz., five

FIG 14—A DIPLOPORITE CYSTOID

radials, which support the five main food-grooves, five orals, which surround the mouth and lie between the food-grooves, the basals, which lie beneath the radials and form a facet for the stem. The vent lies in one of the interradial, either adjoining, or enclosed by, an oral, the water pore and genital pore are probably associated with it. Respiration was effected through thin portions of the test wall, strongly folded so as to increase the surface, these *hydrospires* cross the sutures between the radial and oral plates. Each food-groove, after passing between the orals, lies not on the radial plate, but on a special plate in the radial line called, from its shape, the *lanet-plate*, this is bordered by small side-plates, to which brachioles are attached.

Crinoida.—The body of the Crinoida (fig 16) is normally borne on a stem, has the food-collecting system upwards, and the vent in the *M* plane at the side or raised away from the intake on a sort of chimney (anal tube). The food-grooves are extended on five arms or brachia, which are not, like brachioles, mere ap-

pendages to the test, but actual outgrowths of the body (fig 7) containing throughout extensions of the body cavities, the generative organs, and the apical nervous system, as well as bearing the usual water vessels with their side branches and podia, and nerves from the two oral systems.

FIG 15—A BLASTOID OROPHOCRINUS FUSIFORMIS

(primatively) five infrabasals, beneath the radials and alternating with them, and often the (primatively) five infrabasals, beneath the radials and alternating with them, are wanting in some groups (monocyclic), present in others (dicyclic), but may be overgrown by the basals or may atrophy in the adult (cryptocyclic). The cup may be enlarged

by the incorporation of the lower parts of the arms, between which other plates (interbrachials) often arise, to make room for the vent, or to support it, special anal plates may be added, or it may be reduced to a small platform as in most feather-stars. The gut, as viewed from the oral surface, is coiled in a clockwise direction (solar).

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

FIG 16—BOTRYOCRINUS DECADACTYLUS OF SILURIAN AGE

floor plates, and that it gave off branches, each of which ended in a podium stretching outwards and a swelling (ampulla) stretching inwards between the floor-plates to form a reservoir, no other Palaeozoan show such a structure. There were no brachioles. The gut seems to have had a solar coil, its vent and madreporite lay

Edrioasteroidea.—The Edrioasteroidea (fig 17) had a circular test composed of an indefinite number of irregular plates. They were either permanently attached to the sea-floor, or adhered like a limpet with some power of movement. From the upturned mouth five food-grooves stretched over the upper face, these were usually borne on a series of alternating floor-plates and protected by hinged cover plates. From the structure of the fossils (fig 7) it is inferred that a water-canal passed from a ring canal round the mouth, beneath each groove but outside the floor plates, and that it gave off branches, each of which ended in a podium stretching outwards and a swelling (ampulla) stretching inwards between the floor-plates to form a reservoir, no other Palaeozoan show such a structure. There were no brachioles. The gut seems to have had a solar coil, its vent and madreporite lay

on the same side as the mouth. In some genera the depth of the food grooves impressed a five rayed symmetry on the generative organs.

Stelliformia.—The Stelliformia (sea stars, brittle star, *et al*) live as a rule with the mouth downwards from it radiate five ciliated grooves with a superficial mucous tract, as in *Pelmatozoa*. the structure of these grooves and of their associated

FIG 17 — EDRIOASTER (SESSILE STAR) COMBINE* ASTEROID STRUCTURE WITH GRINOID HABIT. A UPPER D UNDER SURFACE

your system is just described for *Edistoasteroides* (fig. 7). The creature indeed resembles in *Edistoasteroides* turned down, but differs in that the vent (when present) is on the apical face, which is now uppermost, the vent and siphon pore are no longer both in the same interradius while the madreporite is shown in fig. 12, still marks interradius C/D of the apical plane, the vent has moved into B/C. In correlation with the apical, food collecting by dilated grooves has given place to active search for and ingestion of animal food, alive or dead in liquid portions, this again has led to modification of plates round the mouth into jaws, and to prolongation of the ambulacra on rigid extensions of the body, giving the animal first the star shape (fig. 1) then the form of a disc with five arms (fig. 2). The terminal plate of each arm is separated from the apical pole by a stretch of plated intersegment, the grooves never bend round on to the upper surface. Since each terminal plate bears an organ sensitive to light it is also called an ocellus. According as the move by crawling or wriggling recent *Stelleroidea* fall into two classes, *Asteroida* and *Ophuroidea*. In the *Asteroida* (fig. 2) the ambulacral grooves remain open and the nodal change into tube feet, with or without

face. Podia and papulae are protected by thorns or spikes, which are sometimes clumped (paxillae), sometimes branched and bearing a membrane, sometimes modified into small grasping organs (pedicellariae). Many sea stars have more than five arms, but the arms never fork.

The Ophiuroidea (the name means snake tail forms) owe their name to the long, thin, flexible arms, which spring abruptly from the central disc (fig. 2). The arm groove is covered, the podia cease to act as solid feet, the floor plates are thickened and joined by pairs into tube bones shaped like vertebrae and connected by strong muscles. In a few types genital glands but not digestive caeca, extend into the arms. The outer plates of both disc and arms in broad shields without interspaces for papulae. Some times aeration is through clefts in the basals of the arms. The spines remain small and usually of simple structure. Few ophiuroids have more than five arms, but in one order including the basket fish the arms may fork from a few to very many times.

Echinoida—The Echinoida (see *Urchins*, figs. 1, 19) also lie roughly downwards. A simple regular echinoid may be compared to an asteroid in which the vent is at the apical pole, and the grooves have grown round on to that face of the test (fig. 18). So that their terminal oral plate (anure the vent and are commonly separated from it by five other plates of rather larger size, each pierced by an opening for the extrusion of the genital products (hence called genital plates), and one also pierced by numerous water pores (madropore). The test having become rigid as well as globular, the soft structures of the grooves have sunk beneath it, and the podia emerge through the plates (fig. 7). The absence of papillae from the close built test throws most of its purratory work on the podia, and to aid this the canal of each is divided, and cilia sweep a current up one half and down the other, thus the pores for the podia are double, like the diplopores of cystoids. The plates through which the podia pass are called 'ambulacral', new evidence suggests that they correspond to the floor-plates of Asteroidea and Echinozoidea, not to the cover-plates or to any structure in Crinoidea, Cystoidea or Blastoidea. The genital glands are much branched, and here remain interradial. In a regular echinoid (fig. 3) the madreporic and vertical axis mark the M plane, the vent is not precisely at the apical pole, but is shifted in the direction of radius B (fig. 12). According to S. Loven, the plates of the five interradia are symmetrical with regard to the plane B/D/E, which therefore is called the echinoid plane. In a large number of later sea-urchins the vent moves towards the underside of the test, whence such forms are called irregular echinoids (fig. 10). In most the vent passes along interradia B/A, while the mouth moves in the other direction along radius D, the plane thus marked is known as Loven's plane. In such urchins the groove D is termed anterior, and, with the adjacent C and E, forms the trivium, while grooves A and B form the bivium. These are not the same rays as form the so called trivium and bivium in the other classes. The change to irregular is connected with a change in the mode of feeding. Regular echinoids have five teeth, interradially placed and held in a frame of 20 pieces, which Aristotle compared to a ship's lantern. In those later forms that take to feeding on ooze or minute food, this structure is gradually lost.

a sucker at the end by which the set star clings to objects or pulls itself along, a podium can be withdrawn into the groove by its muscles, when its fluid contents pass into the ampulla, contraction of the ampulla squeezes the fluid up into the podium, swelling it out for use. The arms are 10, as a rule, sharply distinguished from the body, and they contain both genital glands and blind extensions of the digestive system (coeca). The body-fluids are aerated through thin-walled outgrowths of the body-cavity (papulae) which pass between the plates or the under sur-

are always present and are of five different types

Holothuroidea—The Holothuroidea (holothurians, sea cucumbers) resemble the Echinoidea in that the outer skin covers the grooves, podia may or may not be present. But, whereas a sea urchin moves sideways in any direction, a normal holothurian (fig. 5) moves only in the direction of its mouth, with the body stretched along the sea-floor, and the vent at the other end. The surface turned to the sea floor is always the same, and is usually flattened down its middle line is one of the radii (A), with radius B to its right and E to its left (fig. 12), the podia of these radii serve as sucking feet, but those of radii C and D, on the upper surface, are used only for feeling and aeration. Near the front or mouth end of the middle upper interradius C/D opens the duct from the usually single genital gland, while the water pore opens just in front of it in the larva and in the adult too in some species, in others the pore closes and the water system obtains its fluid from the body cavity through openings in the stone canal. There is no apical system of plates, and no terminal plate or special tentacle at the end of each ray. In these respects and in the symmetry of the rays the holothurians depart from other Eleutherozoa and approach such early Pelmatozoa as *Echinoaster*.

The following special features are found in most holothurians (fig. 20). The mouth is surrounded by the 8–30 (usually 10–20) front podia, which have become prominent tentacles. Outside these is a rim, which can close over both mouth and tentacles. The body wall has two sets of muscles: a transverse, circular layer, which, on contraction, compresses the contained fluids and thus elongates the body, five pairs of longitudinal muscles, along side the radii, which on contraction shorten the body (it is hard to hold a holothurian). The gut passes from the mouth, below interradius C/D to the hinder end of the body, then forward along interradius D/E, then downward along A/B to the vent, thus it has a solar coil as in ctenoids and edinooids. Most holothurians suck in water through the vent for aeration, to accommodate this the rectum is enlarged and, in numerous species, gives

FROM SEDGWICK, STUDENT'S TEXT BOOK OF ZOOLOGY* (ALLAN & UNWIN LTD.)
FIG. 20—A HOLOTHURIAN OPENED ALONG THE BACK

off two many-branched tubes with blind ends, termed the respiratory trees. In most holothurians the skeleton is greatly reduced. Round the gullet is usually a ring of five radial and five interradial pieces, which may correspond to the mouth frame of echinoderms. There are no regular plates in the body-wall, but throughout the skin and the connective tissue are scattered minute spicules, which have different shapes characteristic of the various genera and species; in one or two genera some of these are enlarged to form irregular plates, and in one or two they are absent altogether.

REPRODUCTION AND DEVELOPMENT

In most echinoderms the sexes are separate, but not distinguished by any external characters. The gametic products are discharged into the water, where the eggs are fertilized by the sperm. The egg then divides into a number of cells, which form a hollow ball. One end of this grows inward, and the result is an open mouthed larva with a double wall. This stage corresponds to the

FROM NORTON, NORDISCHES PLANKTON (PREUSSISCHE AKADEMIE DER WISSENSCHAFTEN)
FIG. 21—THE EARLY STAGES OF LARVAE OF VARIOUS ECHINODERMS

structure of the jelly fish, etc. (Coelentera). From the walls cells migrate into the space between, forming a middle layer. The body cavity arises from the hollow of the sac as a single pouch growing out into the loose middle layer. By repeated division of this pouch arise the three pairs of coeloms shown in the diagram of the dipleurula (fig. 9). Meanwhile the sac lengthens and is flattened on one side, toward which the original cavity bends down and breaks through to form the larval mouth, leaving the original opening as the larval vent.

The larvae are free swimming, and are modified from this ground plan in five directions according to the class to which each belongs. They used to be regarded as distinct animals, and so received special names. Of the four types of pelagic larvae of Eleutherozoa the simplest is the holothurian, of which an early stage is shown in fig. 21. The primitive mouth is surrounded at a little distance by a band of cilia, which by their vibration move

FROM NORTON, NORDISCHES PLANKTON (PREUSSISCHE AKADEMIE DER WISSENSCHAFTEN)
FIG. 22—LARVA FIXED TO SEA FLOOR AND YOUNG STAR

the larva. A smaller ciliated band immediately round the mouth sweeps in food. The oral field, within the main band, is shaped like a broad Π , in later stages the two side portions are folded on their borders and look like a pair of human ears, whence this larva has been called *Auricularia*. The vent lies in the middle below the crosspiece of the Π , and the gut runs through the curved body to it, swelling on its way into a stomach but showing no twist. This larva has no skeleton, only some wheel-shaped spicules scattered through its substance. The larvae of brittle-stars and sea urchins have a skeleton, in which long rods push out the side folds and so increase the length of the ciliated band, early stages are shown in fig. 21. A fancied resemblance of later stages to a painter's easel led J. Muller to call the larva *Pluteus* (easel). In the arrangement of the rods the *Ophiopluteus* differs somewhat from the *Echinopluteus*. The asterooid larva has no skeleton. It differs from the auricularia in the meeting of the two upper limbs of the Π , so that the oral field is like an Λ , and there are two complete ciliated bands (fig. 21), their apices are drawn out into long prae oral lobes, and their margins are folded into narrower lobes or pinnae, whence the larva was called *Bipinnaria*. In the recent unstalked ctenoids and some other echinoderms with large yolky eggs, the larva grows within the egg till it emerges as

a barrel shaped form with five bands of cilia like the hoops of the barrel, the primitive mouth, being unused, closes

Between the larva and the adult is a series of complicated changes, during which the larval skeleton is absorbed and re-deposited as the permanent skeleton, while portions of the creature are often cast aside as worn out trappings. Such a marked change is called metamorphosis (*gry*). It is best known in some of the sea stars, where it takes about 15 days. The larva sinks and attaches itself to the sea floor by a portion of the pre-oral lobe (fig. 22) thus is pulled out into a stall, and the future star developed within the body of the larva. The essential change is the curving of the left hydrocoel and the left hinder coelom round the gut, till each becomes a ring. In the asteroid the oral face of the star bends downwards towards the stalk and the floor, and the water ring closes round the stalk which then disappears (fig. 24). In the ctenoid the oral face is bent upwards, so that the water ring does not enclose the stalk (fig. 23). As shown in fig. 12 the water ring closes in a different interradial with reference to the M plane in each class, this is connected with the torsions that occur during metamorphosis. The later stages of growth are often of interest to the evolutionist as suggesting the ancestry of the present form and the origin of its special structures. The classical instance is the rosy feather star (*Antedon bifida*). This was thought to be an asteroid, but in 1823 J. V. Thompson, a Cor. surgeon, discovered that when quite young it was fixed by a stalk like a ctenoid, the growing animal breaks away from the root, and the upper part of the stalk is condensed into a knob bearing numerous stem (indusils or cirri). This process recapitulates the race history traced in Jurassic fossils.

Protection of the Brood.—Although most echinoderms have free swimming larvae, about 60 keep their young with them until they are large enough to shift for themselves. These brood protecting species are found in all the groups, but are most numerous in the holothurians, starfishes and brittle-stars. Especially characteristic of sub antarctic regions, there are less than a third as many in the arctic, and only a few in tropical and temperate seas. The young may be carried on the outside of the body, generally distributed, or segregated in special areas, as in the deeply sunken

brittle-stars snap the arms when seized and disintegrate before the distressed naturalist, some holothurians, when attacked, eject portions of their viscera and to this habit the cotton-spinner owes its name. The discarded portions can be grown again, it has even been claimed that in some cases they can themselves grow fresh bodies and become complete individuals. A sea star (*Lucina*)

FIG. 23.—DIAGRAM SHOWING CHANGE FROM FIXED ECHINODERM TO FREE

commonly avails itself of this faculty, and ope may find small arms with a small body at one end, and four little buds growing out of it, these are known as comet-forms. The power of regeneration is probably due to the extension of all the systems of the body into the arms, but it seems that in general a portion of the central disc must also be present. A development of this power is reproduction by spontaneous division, as practised by many sea-stars, brittle stars and holothurians, it is indeed the usual method in a number of small six armed tropical brittle stars which when young commonly have three larger and three smaller arms

GEOGRAPHICAL DISTRIBUTION

Echinoderms are confined to the sea and differ in this from all but one or two branches of the animal kingdom. The limitation is probably connected with the density of the water, since echinoderms depend largely on their hydraulic system, and there is besides a constant interchange between the internal fluids and the outer water through the thin membranes. Any sudden change would be particularly fatal to the larval stages, which transport the species to other localities. Some species tolerate a change better than others, but few are found even in brackish water. Within the sea, however, echinoderms may occur from anywhere between tidemarks down to 6,000 metres (34 miles). Those between tidemarks are often buried in moist sand, some urchins bore holes in rock, and these retain a little water, few can stand being left high and dry. In littoral waters examples of all classes are numerous, but the greatest abundance and variety occur between 1,000 and 2,000 metres, in the greater depths both species and individuals are fewer. Most species have a limited range of depth, but a few have considerable extension, thus, the brittle-star *Opheocephala bifida* ranges from 5 to 4,450 metres. No order and few families are exclusively either littoral or abyssal, but two highly modified kinds of holothurians occur only floating in the open sea.

Since the depths of the sea are connected and their conditions more or less uniform, abyssal species are much alike in all the oceans. The conditions of coastal waters are varied, and so, consequently, are the species, few having a really wide distribution, the chief exceptions are circumpolar species, which may stretch

FIG. 24.—DIAGRAM SHOWING THE INTERNAL STRUCTURE OF THE PRIMITIVE PELMATOZOON, PRODUCED WHEN THE BIPIEURULA FIXED ITSELF BY THE HEAD CAUSING THE MOUTH TO MOVE UPWARDS AND SO THROW THE GUT INTO A COIL AND BEND THE BODY CAVITIES

ambulacra of certain irregular echinoids, or clustered about the mouth, as in certain starfishes, or in the feather stars attached to the cirri or pinules. Often they develop in special pouches which may be on the upper surface as in some holothurians and starfishes, in the interradial areas as in some brittle stars, or on the pinules in some feather-stars. In some cases they are developed internally, escaping through rents in the body-wall of the adult.

Self-division and Regeneration.—Many echinoderms can break off portions of themselves, generally under the stimulus of danger or to get out of a difficult situation. The stem and arms of some of the later ctenoids have special breaking-planes, some

GEOLOGICAL HISTORY AND EVOLUTION

Geology gives only a succession of fossil forms, the relation of these to one another is interpreted through facts of anatomy and development, and seen to be an evolution. In its main lines the race-history is now thought to have been as follows. We start with a dipleurula larva (fig 9), still free floating and with none of the peculiarities of the modern adult echinoderm. The event that originated the branch was the discovery of the sea floor, on which followed the adoption of a stationary life and the deposition of lime spicules in the skin. The three-rayed spicules grew into star shaped plates loosely joined, such as are scattered in Lower and Middle Cambrian rocks. As the plates grew, they were more firmly united, and complete skeletons were preserved. These, at the outset, show a divergence. The *Machaeridia* (fig 10) may represent the elongate stage before fixation. If the elongate form became fixed by the middle of its body, the mouth and the vent would be on the two sides of the base of attachment, and from such a creature all the nonradiate *Carpoeida* (fig 11) may have descended. They are found only from Middle Cambrian to Devonian.

Origin of Radiate Forms—Radiate forms had a different origin. The dipleurula, apprehending the floor by its sensory front end, fixed itself, not by the ciliated pole, but a little to one side, the right side being chosen for a reason we cannot yet fathom. The result was the passage of the mouth to the upper surface (fig 23). As it passed up along the left side, the gut caught hold of the left water-sac and pulled it upwards, curving it in the process. Since this was attached to the left duct from the front body cavity, that structure was also pulled up and its pore came to lie between mouth and vent, while the stretched part of the front cavity formed a canal lying along the outer wall. The gut, as it coiled, drew the left hinder coelom also upwards in a curve, while the stomach pressed the right hinder coelom down to the fixed end, where it was involved in the elongation of that region. Not only can these changes be traced in the developing *Antedon* today, but several of the older cystoids had the structure of such a primitive pelmatozoan. Notably they retain the pore by which the genital products, formed from the canal alongside the body-wall, were extruded. At this stage no radiate structure was visible, but, unlike *Carpoeida* and *Machaeridia*, these forms had the fundamental plan on which the radiate types were built.

Radiation arose from the mode of feeding combined with the effect of gravity. Fixed to the sea-floor, with its mouth upturned to the food-bearing waters, which it swept inwards by the cilia of the gullet, the primitive pelmatozoan extended its food collecting surface by the outgrowth of ciliated channels from its mouth

FIG 25.—SUPPOSED ANCIENT ECHINODERM BOTHRIODICARIS SHOWING (RIGHT) ARRANGEMENT OF PLATES AROUND THE VENT

as already described under *Cystoidea*. A limit was set to this increase by the size of the body itself.

Crinoids and Feather stars—Another class, based on a better plan, appeared first at the close of Cambrian time, and by the close of Devonian time had taken the place of the cystoids, this class was the Crinoidea. Here the length of the food grooves was increased by the actual outgrowth of the body wall in the direction of the five rays but upward, the outgrowths became jointed, and repetition of the process led eventually to the long and many-branched arms of the crinoids, in which the grooves sometimes reach the combined length of a quarter of a mile. The

Crinoidea early blossomed into some half dozen orders and became adapted to every habitat which the sea provides. A single instance may be taken from certain shore dwellers which in Jurassic times found safety by shortening their stem while retaining the whorls of crin, with these, when torn away by the waves, they could grasp the nearest object. Eventually the stem was fused with the lower part of the cup into a hemisphere covered with crin. Acquiring some power of free locomotion, this type expanded into the group of Comatulida (feather stars), which today comprises about 600 species, divided among 140 genera (fig 4).

Sea stars and Brittle stars—Among the oldest known echinoderms is a genus of Echinozoa, a class in which radiation had affected not only the food-grooves but the hydraulic system. Though clearly Pelmatozoa, they provide a starting point for all classes of Eleutherozoa. Most adhered by a sucking action of the flexible under side to smooth surfaces. Through the thin skin of that side, the genital products, it is suggested, were extruded. At that time, if at no other, the creatures were liable to be overturned, and those that could use their podia for locomotion would have an advantage. A sea star is little more than an overturned *Edrioaster*, and some even now retain the power of feeding in the pelmatozoan way. The anatomical changes in adaptation to the new mode of life have been explained under *Stelliforma* (fig 24). Fossils of the crawling asteroid type are known from the top of the Cambrian, but are rare until the Upper Silurian and Lower Devonian, when some adopted a wriggling habit and a structure tending towards the ophiroid type. Genera with arm grooves completely closed and with all their floor-plates turned into "vertebrae" are of doubtful occurrence earlier than the Carboniferous. Ophiroids with elaborate vertebrae of modern type appear first in the Trias.

Sea urchins—The first echinoids may also have been derived from overturned edrioasteroids, the vent, as it passed up, was dragged a little farther back, leaving room for the madreporite, with which it became closely associated at the apical pole. The earliest known are from the top of the Ordovician. For half-a-century *Bothriodicaris* (fig 25), a small fossil from Esthonia, has been regarded as an ancestral echinoid, but T. Mortensen, after fresh examination, refuses to accept it. This leaves in the Ordovician and Silurian only many-plated forms with flexible test, they cannot be derived immediately from *Edrioaster* since they already have well developed jaws. The family *Lepidodictidae*, to which they belong, continues to the Carboniferous. Nearly all Palaeozoic echinoids have more than the 20 columns of plates found in later genera, among them the *Archaeocidaridae*, apparently existing in the Devonian, are nearest the simple cidarid type, which has a solitary representative in the Carboniferous and another in the Permian. The early cidarids retained some flexibility in the union between ambulacral and interambulacral areas, in the Triassic period this gradually gave place to a rigid union, and at the same time appeared the diademoid type, with external gills, close set podia, and more numerous radioles. *Cidaroida* and *Diademoida* have persisted to our own day, the former relatively unchanged, the latter giving rise to successive suborders. Among these, some Jurassic genera show the beginning of that movement of the vent towards the margin which characterizes the irregular urchins. A side-branch originating in Cretaceous times was the *Clypeastroidea* (shield-urchins) as an adaptation to life just below the sand of the shore. Another modification led to elongate urchins in which the jaws were gradually lost as the animal took to extracting nutriment from ooze. The extreme of this line is reached in the modern *Spatangidae* (heart-urchins).

Sea Cucumbers—The coiled gut and radiate hydraulic system of the Holothuroidea suggest that this class also was derived from a primitive pelmatozoan. At an early stage the creature took to locomotion in the direction of the mouth, with consequent worm-like lengthening of the body, possibly facilitated by the less calcified integument. Already in Middle Cambrian shales are found the compressed imprints of soft-bodied animals with apparent holothurian structure. The closure of the food-grooves, the elaboration of mouth-tentacles, the suppression of the unused podia on the back, and the retention of the single genital gland with its

poore were all natural consequences of this mode of life. Spicules ascribed to holothurians have been found fossil from the Cambrian onwards, but the general absence of other skeletal structures prevents one from tracing the history of the class

NATURAL HISTORY

Echinoderms are sluggish and frequently immobile for considerable periods. The brittle-stars are the most rapid movers. Free forms shun the light and hide or bear a cloak of seaweed by day. Their often brilliant colouring can rarely have protective value. Some sea stars light the depths with glorious phosphorescence, and many littoral brittle stars phosphoresce when stimulated. This also may be a useless by-product of some activity. The general mode of life and nutrition have been mentioned under the various classes, and further details are given under STAR-FISH and SEA URCHIN. Holothurians feed by sweeping minute creatures into the mouth with large shield-shaped tentacles, or by catching them with the slimy surface of bushy tentacles which they push into the mouth and withdraw cleansed. Abyssal holothurians live and feed on the ooze, breathing by the podo of the back, which are often monstrously developed. In some holothurians portions of the respiratory trees consist of slime-secreting cells, when irritated, the animal compresses its body and forces the tubes out of the vent, the slime absorbs water and swells enormously, finally splitting into sticky threads in which an enemy can be hopelessly entangled. Many animals live in or on echinoderms as mesomates among them: as protozoans, sponges, annelids, crustaceans, molluscs, and, most notably, a fish, *Furcasfer*, which enters the respiratory trees of holothurians. Parasites are even more numerous. Besides the groups mentioned, they include nematodes, trematodes, a myxomycete, and the myxosomites of uncertain affinity, found chiefly on ctenoids. Many of these unwanted guests assume the livery of their host, and frequently compel structural changes. A number of brittle stars are symbiotic or parasitic on coelenterates, feather-stars and sea urchins.

Economic Aspects.—In the economy of nature, echinoderms play a larger part than in that of man. The ctenoids and other Palaeozoic stem useless, yet they have extracted from the sea millions of tons of lime and built up huge masses of rock. Derbyshire marble, Belgian *petit granit*, the *Trochiten-kalk* of Germany and many of the Oolitic freestones are largely formed of their remains. Holothurians in the sea, like earthworms on land, pass the loose detritus perpetually through their bodies, extracting the organic nutriment, and thus acting as cleansers. The same task is performed by many heart urchins, while most of the other free-moving forms, especially the sea-stars, are scavengers on a larger scale. Unfortunately sea stars do not confine themselves to carrion, but attack living molluscs, among them oysters and mussels, doing terrible damage (see STAR-FISH). On the other hand some of the smaller kinds are eaten by bottom-fishes, and thus help to turn nature's waste into marketable food. For the immediate food of man most echinoderms are unsuitable, but some holothurians are used in the east. (see BICHE DE MER), and in various parts of the world the ovaries of the larger regular sea urchins are much appreciated. The ease with which the eggs of echinoderms can be fertilized and the early stages of development reared in the laboratory has led to their extensive use as material for research into fundamental problems of life and growth.

History.—During the 18th and first half of the 19th centuries, echinoderms were described by many eminent naturalists. Echinoida by J. T. Klein, C. Linnaeus, N. G. Leske, E. Desor and I. Agassiz, Stelleroidea by J. H. Linck, Ctenoida by J. S. Miller, Cystoida by L. v. Buch, but it was the researches of Johannes Müller (1840-50) that laid the foundation for a scientific treatment of the branch. For the host of later writers on this large and varied group, reference must be made to the works cited in the bibliography.

Bibliography.—An annual index to all publications on Echinoderma has for many years appeared in *Zoological Record* (London, Zool. Soc.). General works are:—H. Ludwig and O. Hamann, "Echinodermen" in Bronn's *Klassen und Ordnungen des Tierreichs* (1889-1907), full bibliographical accounts of recent forms, F. A. Bather, E. S. Goodrich, J. W. Gregory, "Echinoderma" in Lankester's *Treatise on*

Zoology (1909), bibli., recent and fossil, full on Palaeozoica, E. W. MacBride "Echinodermata" in *Cambridge Natural History*, T. (1906), good on habits, T. Moitensen, *Handbook of the Echinoderms of the British Isles* (1927), bibli., good for the zoologist on both sides of the Atlantic. Special Groups are approached on broad lines in:—T. H. Withers, *Catalogue of the Macrasteria* (1926), Nat. Hist. bibli., O. Jaekel, "Phylogenie und System der Palaeozoica", *Palaeont. Zeitschrift* (1918), A. H. Clark, *Monograph of Existing Crinoids* (1915-41), F. A. Bather, *Studies in Edrioasteroidea* (1915), W. K. Spencer, *Monograph on Palaeozoic Asterozoa* (1914), Stelleroidea, H. Matsumoto, "Monograph on Japanese Ophiuroidea", *Journ. Coll. Sci. Tokyo* (1917) new classification, W. K. Fisher, *Asteroidea of the North Pacific and Adjacent Waters* (1911-30), bibli. (F. A. B., A. H. Ck.).

ECHINOIDEA, a class of the Echinodermata (q.v.), comprising the sea urchins (q.v.), heart-urchins and sand dollars.

ECHINUS, in architecture, a convex moulding, under the abacus of a column capital so called from its resemblance, in form, to a sea urchin (Greek *echinos*). It is universal in both Greek and Roman Doric orders, in which it has a profile of circular or elliptical curvature, Roman examples have a *cyma recta*, double curved (see CYMA) profile. The convex moulding between the volutes of the Ionic order is termed an echinus, as is any similar form in a capital of any style. (See ORDER.)

ECHIURIDA, a group of marine worms comprising a phylum of the animal kingdom which, in spite of an apparent lack of segmentation, must be considered nearly related to the Annelida (q.v.). Although formerly placed in the obsolete phylum Gephyrea, together with Sipunculida (q.v.) and Priapulida (q.v.), they have little in common with the former while it is probable that supposed relationships with the latter can be altogether discarded.

THE SPOON WORM, A TYPICAL REPRESENTATIVE

Spoon worms (figs 1 and 2) are moderately large, sac-shaped creatures that inhabit U-shaped tubes on sandy mud bottoms. The northern cold water species, *Echinurus echinurus*, is described below as an example.

FIG. 1.—SPOON WORMS

(LATER FISHES AND MAGGOTS).
A—*Urechis caupo* (1) in its burrow, showing the slime tube (2).

(LATER ORFIS).
B—*Echinurus echinurus* (1) Prostomium (2) ventral setae (3) genital openings (4) anal setae.

External Characters.—The body consists of a cylindrical trunk which reaches a length of 12 cm or more, and a preoral lobe or prostomium, shaped like a hemispherical fan when fully extended, which is about half as long as the trunk. The prostomium is ciliated on its ventral surface and its margins are fused at the base, forming a funnel around the mouth. During feeding the prostomium is extended over the surface of the surrounding mud, and particles of detritus are swept along ciliary tracks towards the mouth.

The trunk is encased by rings of mucus-secreting papillae, the slime being used to line the walls of the burrow. The anus is terminal.

Autotomy.—The prostomium is so readily autotomized that few people have ever captured an intact specimen. The musculature of the body wall is thinned in a special autotomy ring behind the mouth and in front of this there is a powerful sphincter muscle which upon sudden contraction, discards the anterior end. The trunk regenerates the missing parts within a few weeks and feeding is then resumed.

Setae.—At the anterior end behind the mouth there is a pair of powerful ventral setae which are used in burrowing. At the posterior end there are two incomplete rings of smaller setae, interrupted ventrally, which are used in cleansing the burrow. The setae are exactly similar to those of annelids, each is formed by the secretion of a single basal cell, and when an old worn seta is discarded its place is taken by a new one derived from a reserve follicle. Muscles corresponding to the protractors of an oligochaete move the seta forwards, backwards and sideways, other muscles, including an interbasal, move the two ventral setae apart.

Body Wall.—The skin consists of a simple columnar epithelium which, except on the ciliated regions of the prostomium, secretes a thin cuticle. The subepidermal connective tissue layer contains yellow

and red pigment cells. The muscular coat consists of three layers, circular, longitudinal and oblique, of which the longitudinal are most strongly developed. A peritoneum separates the body wall from the spacious coelom.

Body Cavities.—The cavity of the prostomium is a system of canals and lacunae which are separated from the true body cavity by an incomplete partition, the diaphragm. They are provided with an endothelial lining, and coelomic fluid moves freely between the two compartments, yet it can be shown that the prostomial cavity is derived from the embryonic blastocoel which develops a secondary connection with the coelom (fig. 3). On this account F. Baltzer has likened the body of an echiurus to a chimaera in which the anterior part is larval and the posterior part adult.

Coelomic Fluid.—The coelomic fluid contains two types of cells, spherical erythrocytes which, in the Californian species *Urechis caupo*, are known to contain a respiratory pigment similar to haemoglobin, and amoeboid leucocytes often laden with red-brown pigment granules. In addition, in all but the youngest individuals, there are mature sperm cells. The coelomic fluid thus performs respiratory as well as nutritive and excretory functions. Respiratory exchanges take place in part through the skin, since the worm keeps up a constant flow of water through the burrow by peristaltic contractions of the body. Water is also taken into the anal vesicles and expelled periodically. According to the investigations of A. C. Redfield and M. Florin, the properties of *Urechis* haemoglobin are such that it serves as a reservoir, giving up its oxygen to the tissues only during periods of deficiency when the worm is confined to its burrow by exposure at low tide.

The coelomic fluid of *Echiurus* is isotonic with the sea water in which it lives and, as is commonly the case among invertebrates, contains no plasma proteins in solution.

Digestive System.—The mouth communicates with the pharynx, which makes a double loop in the region of the diaphragm, a thick-walled oesophagus is dilated posteriorly to form a crop in which the food bolus is moulded. These parts, constituting the fore-gut, are of mesodermal origin. The endodermal mid-gut is separated from the fore-gut by a sphincter, it is divided into three regions, the pre-mid- and post-intestine. The mid-intestine is accompanied by an accessory tube of smaller diameter which is continuous before and behind with an open ciliated groove. This accessory tube or aphron is of unknown function and, although similar structures occur in unrelated groups, as for example among polychaetes (Capitellidae) and in sea-urchins, its presence is considered to be one of the more distinctive features of the Echiurida. The post-intestine opens into a short anal tube, also of endodermal origin. Both mid- and post-intestine are strongly coiled and convoluted. The intestinal juice is alkaline and contains a powerful proteolytic enzyme. A lipase is also present but evidence for an amylase is inconclusive.

Excretory Organs.—The anal tube receives a pair of endodermal sacs, in the newly metamorphosed larva these sacs communicate with the coelom, each by a single nephro-tome, in the adult the number of nephro-tomes is great increased. The anal vesicles are highly characteristic of the phylum. They serve as both excretory and respiratory functions, and since they are provided with typical nephro-tomes, they probably represent a poeior put of metanephridia.

Vascular System.—The vascular system is closed, a ventral vessel runs the whole length of the trunk above the nerve cord and bifurcates anteriorly to form a ring around the margin of the prostomium. A short dorsal vessel, confined to the anterior part of the body, receives blood from the ventral vessel by means of a simple transverse mid-gut. It pumps the blood forward into a median prostomial vessel which communicates anteriorly via the marginal loop with the ventral vessel. The blood is colourless and contains only phagocytic amoebocytes.

Nervous System.—There is a ventral nerve cord in which, in the adult, no separate ganglia can be recognized. It is large anteriorly, and the circum-pharyngeal connectives form a long drawn-out loop

which follows the margin of the prostomium. There are no special enlargements of cerebral ganglia. The ventral nerve cord arises embryonically by the union of two ectodermal thickenings and, in *Echiurus*, exhibits 16 transitory ganglionic masses. In *Urechis* the number of these supposedly primary trunk ganglia is only 12 (fig. 3).

Sense Organs.—Groups of sensory cells which may be either tactile organs or chemoreceptors underlie the epidermis and are especially abundant along the margins of the prostomium. Special sense organs are lacking in the adult, but eye spots are present in the larva.

Reproductive System.—In *Echiurus* the sexes are separate but superficially alike. The gonad is suspended from the ventral vessel and the sex products are shed into the coelom during the early stages of their formation. The fertilized eggs grow from 0.01 to 0.2 mm in diam nourished by the coelomic fluid, and are then taken up by the ciliated funnels of the storage organs. In some genera like *Bonellia*, the developing ovum is enclosed in a follicle and nutrition is mediated by a special cap of nurse cells. In males the sperm clusters also develop in the body cavity and the liberated spermatozoa are collected as they become mature and free swimming.

There are two pairs of gonopods, or storage organs, in *Echiurus*, opening to the exterior behind the ventral setae. They are regarded as modified metanephridia and each is provided with a bilobed ciliated funnel which gathers up the mature sex cells and a large thin-walled sac which serves as a storage chamber. In this genus as in the majority of echiurids, the funnel opens into the storage chamber close to its ectal end, in a Japanese species, *Ikeda laenodes*, the funnel is at the ental (internal) end of the sac, presumably a more primitive condition. In some genera (*Urechis*, *Ochetostoma*) the lips are drawn out into spirally twisted, whip-like processes.

Development.—The most complete study is that of W. W. Newby on *Urechis*. Fertilization is external and the early stages show a spiral cleavage similar to that of Platyhelminthes, Mollusca and Annelida. A typical "Annelidan Cross" is formed from cells of the first quartet, but the later stages show a predominance of supposedly molluscan features. Thus the blastopore, pushed forward ventrally by the expansion of the somatic plate, forms only the mouth. In typical annelids the somatic plate, as it grows downward on each side, unites ventrally to divide the blastopore into a mouth forming and an anus-forming region. Although mesoblastic teloblasts are absent in the better known European and North American species, C. N. Dawydoff

has described the appearance of two teloblasts and a transient metamorphism of the mesoderm in the giant larva of an unidentified echiurus from the coast of Annam. In the better known species growth in length is achieved by intercalary expansion of the trunk region and not by the teloblastic addition of segments at the posterior end.

The embryo develops into a free swimming trochophore of the annelidan type, provided with a pair of larval protonephridia.

OTHER ECHIURIDA

The group is a small one comprising about 17 genera with 60 or 70 species described in the literature. The classification adopted below is that proposed by S. Bock (1942) who recognizes three families.

(1) **Echiuridae.**—This family is typically represented by the circum-arctic species *Echiurus echiurus*, described above. The sexes are alike and there are one (*Urechis*) or two rings of anal setae. *Urechis* presents some interesting and rather aberrant features. The prostomium is relatively small and is not used as a feeding organ, food is captured by means of a slime tube (fig. 1A) secreted periodically by a glandular girdle, which filters the water as it is swept through the burrow by peristaltic contractions of the body. The slime tube, together with its catch, is then eaten. It has been estimated that the net must have a mesh with pores of 36 to 40 Angstrom units, since molecules of ovalbumin can pass through while those of serum albumin are partly, and those of haemocyanin completely re-

tained *Urechis* has sometimes been placed in a separate family or subfamily on account of the complete absence of a vascular system. Another peculiar feature is the absence of a definitive gonad, the sex cells are found free in the coelomic fluid from their earliest identifiable stages.

(2) **Thalassematidae**.—Members of this predominantly tropical and subtropical family are distinguished from the Echiuridae primarily by an absence of anal setae. Some thalassematids inhabit the shells of sea-urchins or sand dollars and there are estuarine species from India and Burma which have gill-like processes on the margins of the prostomium. *Arkychile* is a Japanese genus in which the prostomium is completely lacking and Ikeda claims to have shown that this is not, as one might suppose, the result of autotomy. In other genera the prostomium is usually very long and the autotomized prostoma of *Ikeda taenoides* were at one time mistaken for nemertean worms. The most primitive arrangement of the storage organs is found in the genus *Ochetostoma* in which there is a metameric repetition of several, usually three pairs in sequence, strongly suggestive of vestigial segmentation. In *Thalassema* (s.s.) the number has become restricted to one or two pairs, as in the Echiuridae. A culmination of this evolutionary trend is found in some of the Bonelliidae, in which only a single organ remains. On the other hand *Ikeda-soma* has as many as seven or eight pairs, and several of them are represented by groups of organs, it is evident that some of the embryological rudiments have undergone a local, nonmetameric multiplication. This process has advanced so far in *Ikeda*, which has 200 to 400 organs, that all trace of metameric pairing is obliterated.

(3) **Bonelliidae**.—Members of this family are characterized by a pronounced sexual dimorphism. The males are minute and live as parasites upon or within the body of the female. They may be found developing in the pharynx, on the prostomium or attached to the skin and, when mature, they migrate into an antechamber of the storage organ (*Bonellia*) or are otherwise accommodated. In *Pseudobonellia* there is a special invagination of male tube, between the genital pores, the relatively large male of *Acanthohammingia* is found in the body cavity, in *Maxmulleria* the males have not yet been discovered. Except in the possession of functional reproductive organs, the dwarf males present a combination of degenerate and persistent larval features. There is no prostomium and the mid-gut is closed at both ends. A single collecting funnel opens in the male *Bonellia*, into the blind fore gut which functions as a sperm reservoir while the spermatocytes are discharged through the mouth. The excretory organs are a pair of larval metanephridia which do not disappear as they do in the females of nearly all genera.

Females of the Bonelliidae are typical echiurids, anal setae are always lacking and an important character is that the nephrostomes are not sessile but communicate with the anal vesicles by tubules. The majority of species are of an intense green colour, the pigment, known as bonelline, is a mesoporphyrin, chemically a degradation product of chlorophyll. It has been suggested that it is a warning colour, or that it may be distasteful since the green tintures are usually rejected by predators and are poisonous to various invertebrates when eaten. The long, ribbonlike prostomium is frequently deeply cleft or bifurcated but there are three or four genera in which it is simply truncate, as for example in *Protobonellia* and *Maxmulleria*. Ventral setae are lacking in a few forms, like *Hammingia* and *Ikadella*, so that these species are completely sessile. *Acanthohammingia* has numerous very minute ventral setae. *Archibonellia* retains a pair of larval metanephridia and *Sclaterina* is said to be without necessary gut.

Sex-Determination in *Bonellia*—Zoologists have long been interested in this problem and many outstanding contributions have been made, especially by F. Baltzer and C. Herbst. The trochophore becomes transformed into an indifferent larva (fig. 5). At its ends the prostomium of a female becomes attached and remains for several days (B. Herbst) during which period a gradual metamorphosis towards the male condition takes place. It can migrate to the fore gut and from there to the antechamber of the female. For several weeks it remains for at least one breeding season. On the other hand, larvae that develop in sea water usually become females. However, the presence of female extracts, from the fore gut or prostomium,

will stimulate male transformation. The active principle, which resists boiling and is probably not a protein, has not been identified. Moreover, a diversity of foreign agents such as acids, potassium, heavy metals, glycine and even shaking or transference from Mediterranean to North sea water, have been shown to induce masculinity.

The simple facts, outlined above, appear to justify the view that all larvae are potentially bisexual and that the male response is elicited by a variety of different stimuli and is therefore, fundamentally, an irritability. The investigations of Baltzer have shown that when larvae are removed prematurely from the female prostomium they exhibit various stages of male transformation. The degree of intersexuality is approximately correlated with the duration of the attachment period but, since extracts also elicit a graded series of transitional types, it appears probable that organs in the mouth region have a lower threshold towards the male inducing substance than have those situated more posteriorly. Baltzer advanced the view that male transformation is essentially an inhibition. The stimulatory action of potassium led Herbst to suggest, in view of the known effect of these ions in increasing cellular permeability, that an increased water uptake might be the masculinizing agent, and this hypothesis received support from the antagonistic action of calcium. Later Herbst suggested that glycine derived from the melaboliolins in the larval gut must play some role. R. Goldschmidt attempted to bring the facts in line with his famous theory of sex determination while M. Hartman has pointed out similarities with the phenomenon of sex-reversal in the polychaet *Ophryotrocha*.

DOUBTFUL GENERA AND RELATIONSHIPS

Two genera which were formerly placed among the Echiurida are now definitely excluded. *Stenaspis* is a polychaet, and "*Epithetodon*" a nemertean of the genus *Micrura*.

Saccosomatidae.—*Saccosoma* has been removed by S. Bock to a separate order, the Saccosomatinae, of doubtful echiurid status. The species has not been seen since its original discovery. It is said to possess a pair of storage organs but to lack proboscis, setae, anal setae and blood vessels. The body musculature is an inverse order to that found in true echiurids.

Pneobutidae.—*Pneobutis* is a laterally compressed, bathypelagic species regarded by its discoverer, H. Heath, as a connecting link be-

tween Echiurida and Annelida. Interpretation of its anatomy is complicated by the fact that no known echiurids are adapted for a pelagic mode of life. There are no setae. The prostomium may be represented by a pair of grooved tentacles but, in addition, there are five pairs of cirri. Structures resembling anal vesicles are present, but without nephrostomes, and there is a single pair of metanephridia not known to function as storage organs. The ventral nerve cord is strikingly annelid-like, with 11 metameric pairs of ganglia. Septa are lacking.

Relationships.—The Echiurida have many features in common with the Annelida. Distinctive features of the group are the apparent lack of segmentation and the persistent "larval" anterior end which forms the proboscis-like prostomium. It is by no means certain that the lack of segmentation is primary, although W. W. Newby favoured this view. Evidence of suppressed segmentation may be derived from the appearance of transitory ganglia in the ventral nerve cord, from the varying number of setal groups, and from a metamorphic interpretation of the storage organs. Molluscan features are evident in early development and for this reason it is difficult to regard the Echiurida as a degenerate class of the Annelida. Molluscan affinities have also been suggested for the Sipunculida, another unsegmented phylum adjacent to the Annelida but widely different from the Echiurida. Echiurids are clearly more primitive, as shown by the half larval character of their body, and more annelid-like than the sipunculids, as shown by the possession of setae and by the terminal position of the anus. Relationships with the Prapulida are extremely doubtful since the body cavity of the latter is probably a pseudocoel.

Embranchement.—A good general account is given by F. Baltzer in Kuehntal and Krumbach's "Handbuch der Zoologie," Bd. 2, Hfte. 2 (1931), here will be found references to much of the older literature and a summary of the views of the author, at that time, on sedimentation in Bonellia. A shorter account is given by A. Remane, "Echiurida," in *Handie Naturkunde*, vol. 1, p. 153 (1932). There is no modern article in the English language, the best available is probably that written by A. Shipley in *The Cambridge Natural History*, vol. 2 (1901). Classification and taxonomy: a reclassification of the genera was proposed by S. Bock, "On the Structure and Affinities of 'Thalassema' lankesteri Herdman and the Classification of the Group Echiuridae," *K. Yench. Handl. Colebros*, (6), ser. B, Bd. 2, No. 6, 94 pp. (1942), keys to 13 of the 16 or 17 known genera are given by C. A. Monro, "On the Families and Genera of the Class Echiuridae," *Aust. Mag. Nat. Hist.*, ser. 9, vol. 20, pp. 618-620 (1927). keys to genera are also given by W. K. Fisher, "Echiuridae (Worms of the North Pacific Ocean)," *U. S. Nat. Mus. Bull.*, vol. 115-116 (1916), (1916), who proposes a new classification different from that adopted in the present article, *Pocobius* was described by H. Heath, "A Connecting Link between the Annelida and the Echiuridae (Gephyrea armata)," *J. Morph.*, vol. 59, pp. 223-249 (1930), Biology W. K. Fisher and G. E. MacGinitie, "The Natural History of an Echiurid," *Aust. Mag. Nat. Hist.*, ser. 9, vol. 20, pp. 199-204 (1928), G. E. MacGinitie, "The Size of the Mesh Openings in the Mucous Feeding Nets of Marine Animals," *Biol. Bull.*, vol. 88, pp. 107-111 (1945), T. Gislén, "Investigations of the Ecology of Echiurids," *Acta Univ. Lund*, no. 36, no. 10 (1940), C. C. Wilson, "Our North-American Echiurids," *Biol. Bull.*, vol. 1, pp. 167-178 (1900) (names out of date), "Prostomial Gills: an Abstract of Recent Knowledge," is given by B. Prashad, *Proc. Indian Sci. Congress Calcutta*, vol. 23, pp. 346-350 (1936), original description, N. Annandale and S. Kemp, "The Echiuridae of the Lake and of the Gangetic Delta," *Mem. Indian Mus.*, vol. 5, pp. 55-64 (1918), Haemoglobin A. C. Redfield and M. Florin, "The Blood Pigments of Urchins," *Biol. Bull.*, vol. 61, pp. 417-421 (1931), Bonelline E. Lederer, "Sur l'isolement et la constitution chimique de la bonelline, pigment vert de Bonellia viridis," *C. R. Acad. Sci. Paris*, vol. 209, pp. 528-530 (1939), E. Lonnberg and G. Gustafson, "Notes on the Colour Substance of Thalassema Lankesteri Herdman," *Ark. Bot.*, vol. 35, no. 36, (1930), Embryology W. W. Newby, "The Embryology of the Echiurid Worm Urchus Caupo," *Amer. Phil. Soc. Mem.*, vol. 16, contains references to work of previous authors (1940), transient metamorphism is described by C. N. Dawydoff, "Une trochophore géante d'un echiurien des côtes d'Annam Quelques phases de son évolution," *Bull. Soc. Zool. France*, vol. 55, pp. 86-88 (1910), See also the extensive contributions which have appeared since Baltzer's monograph are F. Mutscheller, "Experimentelle Untersuchung der Organe der Weibchen von Bonellia viridis," *Biol. Zentralbl.*, vol. 55, pp. 615-625 (1935), K. Zurbuchen, "Entwicklungsmechanische Untersuchungen an Bonellia viridis n.," *Publ. Stat. Zool. Nap.*, vol. 16, pp. 18-79 (1927), F. Baltzer, *Handl. Colebros*, (6), ser. B, Bd. 2, Hfte. 2, "Untersuchung zur Bestimmung des Geschlechts von und," *Arch. Entw. Mech.*, vols. 134 and 139, pp. 576-599 and 283-302, respectively (1935, 1939).

ECHMIADZIN, (τ) a monastery in the Armenian SSR, in 40° 12' N, 44° 19' E, the seat of the *Catholikos* or primate of the Armenian church. It is situated close to the village of Vagharshapat, in the plain of the Aras, 2,840 ft above the sea, 12 mi west of Erivan and 40 north of Mount Ararat. The monastery comprises a complex of buildings, surrounded

by brick walls 30 ft high, which with their loopholes and towers present the appearance of a fortress. Its architectural character has been considerably impaired by additions and alterations in modern Russian style. On the western side of the quadrangle is the residence of the primate, on the south the refectory (1730-35), on the east the lodgings for the monks and on the north the cells. The cathedral is a small but fine cruciform building with a Byzantine cupola at the intersection. Its foundation is ascribed to St. Gregory the Illuminator in 302. Of special interest is the porch, built of red porphyry and profusely adorned with sculptured designs somewhat of a Gothic character. The interior is decorated with Persian frescoes of flowers, birds and scrollwork. It is here that the primate confers episcopal consecration by the sacred hand (relic) of St. Gregory and here every seven years he prepares the holy oil which is to be used throughout the churches of the Armenian communion. Outside the main entrance are the alabaster tombs of the primates Alexander I (1714), Alexander II (1755), Daniel (1806) and Narses (1837) and a white marble monument erected by the English East India company to mark the resting place of Sir John Macdonald Kinner, who died at Tbriz in 1830 while on an embassy to the Persian court. The library of the monastery is a rich storehouse of Armenian literature (see Brosset's *Catalogue de la bibliothèque d'Echmiadzin* [St. Petersburg, 1840]). Among the more remarkable manuscripts are a copy of the gospels dating from the 10th or 11th century and three Bibles of the 13th century. A type foundry, a printing press and a bookbinding establishment are maintained by the monks, who supply religious and educational works for their coreligionists.

To the east of the monastery is a modern college and seminary. Half a mile to the east stand the churches of St. Ruphime and St. Gaiana, two of the early martyrs of Armenian Christianity; the latter is the burial place of those primates who are not deemed worthy of interment beside the cathedral. From a distance the three churches form a fairly striking group, and accordingly the Turkish name for Echmiadzin is Uch-Kilissi, or the Three Churches. The town of Vagharshapat dates from the 6th century A.D., it takes its name from King Vagarsh (Vologases), who in the 2nd century A.D. chose it as his residence and surrounded it with walls. There the apostle of Armenia, St. Gregory the Illuminator, erected a church in 309, and with it the primacy was associated. In 344 Vagharshapat ceased to be the Armenian capital, and in the 5th century the patriarchal seat was removed to Dyab and then to Ani. The monastery was founded by Narses II, who ruled 524-533, and a restoration was effected in 618. The present name of the monastery was adopted instead of Vagharshapat in the 10th century. At length in 1441 the primate George brought back the see to the original site.

(3) An administrative district of the Armenian SSR, with an area of 3,009 sq km and a population of 113,030, mainly rural. Vagharshapat (see above) is the centre, population 8,035. The district suffers severely from drought, but a scheme of irrigation is now being inaugurated which should greatly increase the cotton production of the region.

ECHO, a sound reflected from an obstacle, personified in later Greek mythology as a mountain nymph or oread (not before Euripides). In Ovid (*Metam.*, iii, 356 ff.) she of fended Hera by keeping her talking and thus preventing her spying on an amour of Zeus, in punishment, she was deprived of speech, save the power to repeat the last words of another. A hopeless love for Narcissus (q.v.) made her fade away to a voice only. In Longus (ii, 23), she rejected Pan's advances, he thereupon drove the shepherd mad, and they tore her in pieces, Earth buried her limbs and allowed them still her power of song.

See Roscher's *Lexikon*, article "Echo."

ECHTERNACH, a town in northeast Luxembourg (see above) in the Sire 18 mi NE of the city of Luxembourg. Pop. (1947) 3,141. Echternach was the centre from which the English St. Willibrord converted the people to Christianity in the 7th century. A Benedictine abbey is represented mainly by an old Romano-Gothic church. The hospital-alms-house is said to be the oldest in Europe save the Hôtel Dieu in Paris. The Benedictine abbey has been greatly shorn of its original dimensions. The basilica was destroyed in 1944 but a new one was begun in 1949 and dedicated in 1953.

The Church of SS Peter and Paul contains the remains of St. Willibrord and stands on an isolated mound, it is reached by 60

steps which are the scene of a remarkable ceremony on Whit-Tuesday. The religious procession (300 singers) under the bishop of Luxembourg, chants St. Willibrord's hymn, it is followed by a miscellaneous band which plays the old German air "Adam Had Seven Sons". Next come the dancers, who take three steps forward and two steps back up the 60 steps. The procession is thus a considerable strain on those who partake but, as the saint is reputed to cure epilepsy, St. Vitus' dance and other illnesses many sick persons try to reach the church. It is said that the ceremony dates from a cholera epidemic of the 13th century. King William I of the Netherlands tried to change the day from Tuesday to a Sunday, so as to avoid loss of a full working day, but the old order re-established itself.

ECIJA, a town of Andalusia, southern Spain, 48 mi. ENE of Seville. Pop. (1940) 25,165 (mun. 34,944). Ecija lies on the left bank of the river Genil, which is navigable to this point, and is the centre of a fertile district producing mainly olives and cereals. The heat in summer is so great that the spot is known as El Sarten, or the "frying pan" of Andalusia. Long famous for its shoemakers, Ecija also manufactures olive oil, soap, flour and preserves.

The city, once enclosed by walls, now in ruins is chiefly remarkable for its Moorish gateways, its church towers studded with glazed tiles, its many fine balconied and decorated mansions and its chief square surrounded by colonnades and planted with acacias. It also possesses 20 convents, now mostly secularized. Ecija, called Estadja by the Arabs, is the ancient Astips, which was raised to the rank of a Roman colony with the title of Augusti Firma and became so flourishing a centre that Pliny and Pomponius Mela, writing in the 1st century A.D., described it as the rival of Córdoba and Seville. Local tradition maintains that it was visited by the apostle Paul, who converted his hostess, St. Xantippe, according to one version of his life, it was the see of St. Crispin in the 3rd century.

ECK, JOHANN MAIER (1486–1543), German theologian, the most indefatigable and important opponent of Martin Luther, was born on Nov. 13, 1486, at Eck, Swabia. His father, Michael Maier, was a peasant and bailiff (*Ansman*) of the village, his uncle Martin Maier, parish priest at Rothenburg on the Neckar, sent him at the age of 12 to the university of Heidelberg, later on to Tübingen, Cologne and Freiburg-im-Breisgau. At the age of 24 he was already doctor and professor of theology. During this period he was known as an opponent of the scholastic philosophy, and, though he did not go to all lengths with the "modernists" (*moderni*) of his day, his first work—*Logices exercitationes* (1507)—was on their side, an attitude which brought him into conflict with the university senate. His position in Freiburg becoming intolerable he accepted in 1510 an invitation from the duke of Bavaria to fill the theological chair at Ingolstadt, where he was destined for 30 years to exercise a profound influence as teacher and vice-chancellor (*Prokanzler*).

A dual commission, appointed to find a means for ending the interminable strife between the rival academic parties, entrusted Eck with the preparation of fresh commentaries on Aristotle and Petrus Hispanus, and between 1516 and 1520, in addition to his other duties, he published commentaries on the *Summulae* of Hispanus, and on the *Dialectics*, *Physics* and lesser scientific works of Aristotle, which became the textbooks of the university. These commentaries are inspired with much of the scientific spirit of the new learning, but he had not sympathy with the revolutionary attitude of the reformers. He won laurels in a public disputation at Augsburg in 1514, when he had defended the lawfulness of putting out capital at interest against Bologna in 1515 on the same subject and on the question of predestination, and these triumphs had been repeated at Vienna in 1516. These successes gained him the patronage of the Emperor and he found himself fairly launched as the recognized protagonist of the established order in church and state. The first fruits of this new position being a quite gratuitous attack on his old friend the distinguished humanist and jurist Ulrich Zasius (1461–1536), for a doctrine proclaimed ten years before and a simultaneous assault on Erasmus's *Annotationes in Novum Testamentum*.

Luther sent to Eck in 1517 copies of his celebrated 95 theses. Eck made no public reply, but in 1518 he circulated, privately at first, his *Obelisci*, in which Luther was branded as a Hussite. Luther entrusted his defense to Carlstadt, who answered Eck in 400 distinct theses, and declared his readiness to meet him in a public disputation, which took place at Leipsig in 1519. On June 27 and 28 and on July 1 and 3 Eck disputed with Carlstadt on the subjects of grace, free will and good works, ably defending the Roman standpoint, from July 4 to 14 he engaged with Luther on the absolute supremacy of the papacy, purgatory, penance, etc., showing a brilliant display of patristic and conciliar learning against the reformer's appeals to Scripture. The arbitrator, declined to give a verdict, but the general impression was that victory rested with Eck. He made Luther admit that there was some truth in the Hussite opinions and declare himself against the pope. He induced the universities of Cologne and Louvain to condemn the reformer's writings, but failed to enlist the German princes, and in Jan. 1520 went to Rome to obtain strict regulations against those whom he called "Lutherans". He was created a protonotary apostolic, and in July returned to Germany, as papal nuncio, with the bull *Exsurge Domine* directed against Luther's writings. He now thought he could crush not only the Lutheran heretics but also his humanist critics. The effect of the publication of the bull, however, soon undeceived him, and he was glad to escape from Saxony with a whole skin. In his wrath he appealed to force, and his *Epistola ad Carolum V* (Feb. 18, 1521) called on the emperor to take measures against Luther, a demand soon to be responded to in the edict of Worms. In 1521 and 1522 Eck was again in Rome, reporting on the results of his nunciature. On his return from his second visit he was the prime mover in the promulgation of the Bavarian religious edict of 1522, which led to years of persecution. In return for this action of the duke, Eck obtained for him, during a third visit to Rome in 1523, valuable ecclesiastical concessions. Meanwhile he published eight considerable polemics between 1522 and 1526.

Luther declined to answer his arguments, and Eck turned his attention to Switzerland and the Zwinglians. At Baden in Aargau in May and June 1526 a public disputation on the doctrine of transubstantiation was held, in which Eck and Thomas Murner were pitted against Johann Oecolampadius. Though Eck claimed the victory in argument, the only result was to strengthen the Swiss in their memorial view of the Holy communion, and so to diverge them further from Luther. At the Augsburg diet in 1530 Eck was charged by Charles V to draw up, in concert with 20 other theologians, the refutation of the Protestant confession. He was at the colloquy of Worms in 1540 and at the diet of Regensburg (Ratisbon) in 1541. At Worms he showed some signs of a willingness to compromise, but at Regensburg he persuaded the Catholic princes to reject the Interim.

Eck died at Ingolstadt on Feb. 10, 1543. He was a powerful debater, but his victories were those of a dialectician rather than a convincing reasoner, and in him depth of insight and conviction were ill replaced by the controversial violence characteristic of the age. His chief work was *De primatu Petri* (1519), his *Enchiridion locorum communium adversus Lutherum* ran through 46 editions between 1525 and 1576. In 1530–35 he published a collection of his writings against Luther, *Opera contra Luderum*, in 4 vols. See also LUTHER, MARTIN.

See T. Wiedemann, *Dr. Johann Eck* (Regensburg, 1865).

ECKERMANN, JOHANN PETER (1792–1854), German writer, born at Berlin, Prussia. He was educated at the University of Berlin, and in 1813 he was given the title of grand ducal councillor and appointed librarian to the grand duchess. Eckermann is chiefly remembered for his

contributions to the knowledge of Goethe contained in his *Conversations with Goethe* (1836-48). To Eckermann Goethe entrusted the publication of his *Nachgelassene Schriften* (posthumous works) (1833-33). He was also joint editor with Friedrich Wilhelm Riemer (1774-1845) of the complete edition of Goethe's works in 40 vols (1839-40). He died at Weimar on Dec. 3, 1854.

Eckermann's *Gespräche mit Goethe* (vols. 1 and 2, 1836, vol. 1, 1848, 7th ed., 1899, ed. by L. Geiger, 1902) have been translated into almost all the European languages, not excepting Turkish (Eng. trans. by Margaret Fuller, Boston, 1839, and John Oxenford, London, 1850). His "remains" were edited by F. Tewes in vol. 1 of *Aus Goethes Lebenskreise* (1905). See Petersen, *Die Entstehung der Eckermannschen Gespräche* (1924); Houder, *J. P. Eckermann, Sein Leben für Goethe* (1925), based on recently discovered letters and diaries.

ECKERNFORDE, a town of Germany, in the *Land* of Schleswig-Holstein, on a fiord of the Baltic sea 20 mi. by rail N.W. from Kiel. Pop. (1949) 23,996. It has a good harbour, fishing, trade in agricultural products and manufactures of tobacco, salt and iron goods. There is a technical school. Eckernforde was taken by Christian IV of Denmark in 1628 from the imperial troops. In 1813 the Dunes were defeated there. The place lost most of its trade after the union with Germany in 1864 and suffered severely from a sea flood in 1872. In the immediate neighbourhood is Borby, popular for sea bathing.

ECKERSBERG, KRISTOFFER (1783-1853), Danish painter, was born at Warnitz on Jan. 2, 1783. He studied in Paris under J. L. David, and then went to Rome, where he worked until 1816 in close fellowship with Thorvaldsen. His paintings from this period—"The Spartan Boy," "Bacchus and Ariadne" and "Ulysses"—testify to the influence of the great sculptor. After his return to Denmark his chief work was done in landscape and sea painting. It is claimed for Eckersberg by the native critics that "he created a Danish colour," that is to say, he was the first painter who threw off conventional tones and the pseudo classical landscape, in exchange for the clear atmosphere and natural outlines of Danish scenery. Eckersberg died on July 22, 1853, at Copenhagen, where he was professor at the academy.

ECKHART, JOHANNES ("MEISTER ECKHART") (1260?-1327), German philosopher, the first of the great speculative mystics of the West, was born at Hochheim, near Gotha. He entered the Dominican order and in 1302 became a master of theology at Paris. Two years later he was made provincial of his order for Saxony, and in 1307 vicar general for Bohemia. In both provinces he was distinguished for his practical reforms and for his power in preaching.

Released from his offices in 1311, Eckhart taught in Paris until 1314, when he was sent to Strasbourg. Later he was transferred to Cologne, where, in 1326, the archbishop took proceedings against his doctrines. In the following year, that of his death, Eckhart publicly declared his orthodoxy and appealed to Pope John XXII. In 1329, 28 of his propositions were condemned by the Holy See.

Eckhart has been termed a scholastic mystic, rather than a mystical scholastic, because he colours the Aristotelian elements in Aquinas with the mysticism of the pseudo-Dionysius. The two most important doctrines in his, as in all mystical systems, are those of the Divine nature and of the relation between God and creatures, especially the human soul.

For Eckhart, God is the absolute and infinite Being best characterized as nothing on the ground that His simplicity is irreconcilable with a plurality of predicates. If any attribute could be ascribed to Him, it would be the *esse* implied in the scriptural *Ego sum qui sum*, though strictly speaking, God is, rather than *has, esse*. In spite of this assertion that the Divine essence and existence are identical, Eckhart goes on to declare that apart from the Divine existence there is nothing *Ens tantum unum est et Deus est*. Every creature has its own essence, but its existence is that of God, and God and the creature are more closely related than matter or form or the parts and the whole. In addition to this pantheistic leaning, the statement that at the

same time that God engendered His Son, co-eternal and equal to Himself, He created the world, brought Eckhart's orthodoxy under suspicion. The statement may not apply to the exterior effect of the eternal act of God, but Eckhart's interpretation of the *in principio* of Genesis as the *nunc aeternitatis* suggests that it does.

Although the Divine existence permeates all being, it is regarded by Eckhart as especially manifested in the human soul, whose end is union with God. This union is to be accomplished through knowledge. The soul must first understand that creatures in themselves are nothing, and then, having perceived the continuity of its being with the Divine being, it can dispense with the external means of salvation and abandon itself to God, Who finds in it His own existence.

Eckhart's style is unsystematic and abounding in symbolical expression, but his successful exposition of scholastic doctrines in an undeveloped tongue has made him the father of German philosophical language.

For the German writings of Eckhart see F. Pfeiffer, *Deutsche Mystiker*, vol. II (Leipzig, 1857, Eng. trans. by C. B. Evans Totel), for the Latin works, H. Denifle in *Archiv f. Litt. u. Kirchengeschichte d. Mittelalters*, n. (1886), German translations by G. Landauer (Berlin, 1903), and Buttner (Leipzig, 2 vols., 1917), M. Grabmann, "Neuauflage und Pariser Quaestiones Eckharts," in *Abhandl. d. Bayer. Akademie der Wiss.* (1917), E. Longpre, "Quaestiones inédites de maître Eckhart," in *Rev. Neoschol.* (1917), A. Daniels, *Une latinité des Reichsrittergeschichten des Meisters Eckhart* (Münster, 1917) and G. Thery, "Edition critique des pièces relatives au procès d'Eckhart," in *Arch. d'hist. doctrinale et litt. du moyen âge* 1 (1926). See further A. Lasson, *Meister Eckhart der Mystiker* (1868), W. Preger, *Geschichte d. deutschen Mystik*, 3 vols. (1874-92), H. Delacroix, *Le Mysticisme spéculatif en Allemagne au XIV^e siècle* (Paris, 1900), A. Spamer, "Zur Überlieferung der Pfeifferschen Eckharttexte," in *Beitr. z. Gesch. d. deutschen Sprache* (1908) and in the same periodical for 1909, M. Pahnke, "Untersuchungen zu den deutschen Predigten M. Eckharts," F. Strauch, *Meister Eckhart Probleme* (Halle, 1912), X. de Horstien, *Les grands Mystiques allemands du XIV^e Siècle* (Lucerne, 1922), O. Karrer, *Meister Eckhart* (Munich, 1926). Ueberweg, *Grundriss der Gesch. der Phil.*, bd. II, containing a full bibliography (1928). (See MYSTICISM.)

ECKHEL, JOSEPH HILARIUS (1737-1798), Austrian numismatist, born at Enzersfeld lower Austria, was for over 20 years professor of antiquities and numismatics at the university of Vienna, and keeper of the imperial cabinet of coins. Eckhel's great work is the *Doctrina numorum veterum* (8 vols., 1792-98). Out of the mass of previously loose and confused facts Eckhel constituted a true science. A volume of *Addenda*, prepared by Steinbuechel from Eckhel's papers after his death, was published in 1826. He died at Vienna on May 16, 1798.

ECKMUHL or EGGMUHL, a village of Germany, in Bavaria, on the Grosse Laaber, 13 m. S.E. of Regensburg by the rail way to Munich. It is famous as the scene of a battle fought here on April 22, 1809, between the French, Bavarians and Wurtembergers under Napoleon, and the Austrians under the archduke Charles, which resulted in the defeat of the latter. Napoleon, in recognition of Marshal Davout's great share in the victory, conferred on him the title of prince of Eckmühl. For an account of this action and those of Austerlitz and Landshut see NAPOLEONIC CAMPAIGNS.

ECLECTICISM, a term used specially in philosophy and theology for a composite system of thought made up of views chosen from various other systems (from Gr. ἐκλέγω, I select). Where the characteristic doctrines of a philosophy are not thus merely adopted, but are the modified products of a blending of the systems from which it takes its rise, the philosophy is not properly eclectic. Eclecticism always tends to spring up after a period of vigorous constructive speculation, especially in the later stages of a controversy between thinkers of pre-eminent ability. Their respective followers, and more especially cultured laymen, lacking the capacity for original work, seeking for a solution in some kind of compromise, and possibly failing to grasp the essentials of the controversy, take refuge in a combination of those elements in the opposing systems which seem to afford a sound practical theory. Since these combinations have often been as illogical as facile, "eclecticism" has generally acquired a somewhat con-

temptuous significance. At the same time, the essence of eclecticism is the refusal to follow blindly one set of formulae and conventions, coupled with a determination to recognize and select from all sources those elements which are good or true in the abstract, or in practical affairs most useful *ad hoc*. Theoretically, therefore, eclecticism is a perfectly sound method, and the contemptuous significance which the word has acquired is due partly to the fact that many eclectics have been intellectual trimmers, sceptics or dilettanti, and partly to mere partisanship. On the other hand, eclecticism in the sphere of abstract thought is open to this main objection that, in so far as every philosophic system is, at least in theory, an integral whole, the combination of principles from hostile theories must result in an incoherent patchwork. Thus it might be argued that there can be no logical combination of elements from Christian ethics with its divine sanction and purely intuitional or evolutionary ethical theories, where the sanction is essentially different in quality. It is in practical affairs that the eclectic or undogmatic spirit is most valuable, and also least dangerous.

In the 2nd century B.C. a remarkable tendency toward eclecticism began to manifest itself. The longing to arrive at the one explanation of all things, which had inspired the older philosophers, became less earnest, the belief indeed, that any such explanation was attainable began to fail. Thus men came to adopt from all systems the doctrines which best pleased them. In Panaetius we find one of the earliest examples of the modification of Stoicism by the eclectic spirit, about the same time the same spirit displayed itself among the Peripatetics. In Rome philosophy never became more than a secondary pursuit, naturally, therefore, the Roman thinkers were for the most part eclectic. Of this tendency Cicero is the most striking illustration—his philosophical works consisting of an aggregation, with little or no blending, of doctrines borrowed from Stoicism, Peripateticism, and the Scepticism of the Middle Academy.

In the last stage of Greek philosophy the eclectic spirit produced remarkable results outside the philosophies of those properly called eclectics. Thinkers chose their doctrines from many sources—from the venerated teaching of Aristotle and Plato, from that of the Pythagoreans and of the Stoics, from the old Greek mythology, and from the Jewish and other Oriental systems. Yet it must be observed that Neoplatonism, Gnosticism, and the other systems which are grouped under the name Alexandrian, were not truly eclectic, consisting, as they did, not of a mere syncretism of Greek and Oriental thought, but of a mutual modification of the two. It is true that several of the Neoplatonists professed to accept all the teaching both of Plato and of Aristotle, whereas, in fact, they arbitrarily interpreted Aristotle so as to make him agree with Plato, and Plato so as to make his teachings consistent with the Oriental doctrines which they had adopted, in the same manner as the schoolmen attempted to reconcile Aristotle with the doctrines of the church. Among the early Christians, Clement of Alexandria, Origen and Synesius were eclectics in philosophy.

The eclectics of modern philosophy are too numerous to name. Of Italian philosophers the eclectics form a large proportion. Among the Germans we may mention Wolf and his followers, as well as Mendelssohn, J. A. Eberhard, Ernst Platner, and to some extent Schelling, whom, however, it would be incorrect to describe as merely an eclectic. In the first place, his speculations were largely original, and in the second place, it is not so much that his views of any time were borrowed from a number of philosophers, as that his thinking was influenced first by one philosopher, then by another.

In the 19th century the term "eclectic" came to be applied specially to a number of French philosophers who differed considerably from one another. Of these the earliest were Pierre Paul Royer-Collard, who was mainly a follower of Thomas Reid, and Maine de Biran, but the name is still more appropriately given to the school of which the most distinguished members are Victor Cousin, Théodore Jouffroy, J. P. Damiron, Barthélemy St. Hilaire, C. F. M. de Rémusat, Adolphe Garnier and Ravaisson-Mollien. (See COUSIN, VICTOR.)

ECLIPSE When the visibility of a celestial body is prevented or reduced by the passage of a second body, the occurrence is called an eclipse (from Gr. *ελεῖν*, failing to appear). The many eclipse phenomena known to astronomers are of two distinctly different types. In the first of these the eclipsing body comes between the observer and the eclipsed object, and the latter appears to the observer partly or completely covered by the eclipsing body. Eclipses of the sun, occultations of stars by the moon, transits of Venus or Mercury across the sun's disk, and eclipses of binary stars are of this kind. Eclipses of the second type affect only planets or satellites which are not self-luminous, here the eclipsing body intervenes between the sun and the eclipsed object. The latter remains in view of the observer, but its illumination by the sun is interrupted, and it becomes darkened by entering into the shadow of the eclipsing body. Examples of this case are eclipses of the moon and eclipses of the satellites of Jupiter.

To the general public, eclipses of the sun and of the moon are of considerable interest as they are readily observable without a telescope and offer an impressive spectacle. Primitive people are struck with fear by the filling darkness during a total solar eclipse or by the weird sight of the eclipsed moon, even animals are disturbed or frightened. Accounts of such eclipses are found among the oldest records of history, battles have been decided by their unexpected advent and the successful prediction of eclipses constitutes one of the earliest triumphs of the scientific investigation of nature.

- We shall divide the consideration of eclipses as follows:
- I Eclipses of the sun
 - II Eclipses of the moon
 - III Eclipses of the satellites of Jupiter
 - IV Other eclipse phenomena
 - V Prediction and calculation of solar and lunar eclipses
 - VI Phenomena and information yielded by observation of solar eclipses
 - VII Total solar eclipses during the 20th century
- I Eclipses of the sun**—An eclipse of the sun takes place when the moon revolving in its orbit around the earth comes between the earth and the sun so that the moon's shadow sweeps over the

FIG. 1.—ECLIPSE OF THE SUN

The shadow of the moon M swept over the surface of the earth E in the darkly shaded region (umbra) the eclipse is total, in the lightly shaded region (penumbra) the eclipse is partial.

face of the earth (see fig. 1). This shadow consists of two parts the umbra or total shadow, a cone into which no direct sunlight penetrates, and the penumbra or half shadow which is reached by light from only a part of the sun's disk.

To an observer who is within the umbra the disk of the sun will appear completely covered by the disk of the moon. Such an eclipse is called *total*. If the observer is within the penumbra, the moon's disk will appear projected onto the sun's disk so as to overlap on it partly, the eclipse is then called *partial*.

As the umbra cone is quite narrow at its intersection with the earth, a total eclipse is observable only within a narrow strip of land or sea over which the umbra passes. A partial eclipse, on the other hand, is visible over the large area covered by the penumbra. Sometimes the earth intercepts the penumbra of the moon but is

missed by its umbra, only a partial eclipse of the sun is then observed anywhere on the earth

By a remarkable coincidence, the sizes and distances of the sun and moon are such that they subtend very nearly the same angle (about $\frac{1}{2}^\circ$) at the earth, but their apparent sizes are not constant. Since the earth revolves around the sun in an elliptical orbit, the distance of the sun varies slightly during the year, and this involves a small change in the angular diameter of the solar disk. In a similar way the apparent size of the moon's disk changes somewhat during the month on account of the elliptical shape of the moon's orbit. Thus when the sun is nearest to the earth and the moon is at its greatest distance the apparent disk of the moon is smaller than that of the sun. If an eclipse occurs at this time the moon's disk passing over the sun's disk may enter completely inside of the latter, leaving the rim of the sun visible all around it. Such an eclipse is called *annular*.

The various phases observable at a total solar eclipse are illustrated in fig 2(A). *First contact* designates the moment when the invisible disk of the moon just touches the disk of the sun. The partial phase of the eclipse then begins as a small indentation in the western rim of the sun becomes noticeable. The dark disk of the moon now gradually moves into the sun's disk and the

FIG 2—SUCCESSIVE PHASES OF SOLAR ECLIPSE
The dark disk of the moon gradually moves across the disk of the sun from west (right) to east (left) (A) Total eclipse (1) First contact (2) Partial phase (3) Second contact beginning of totality (4) Third contact, end of totality (5) Partial phase (6) Fourth contact (B) Partial eclipse (1) First contact (2) Maximum phase (3) Last contact

sun appears in the shape of a crescent. After about $\frac{1}{2}$ hours the crescent grows very thin and daylight appears somewhat dusky. At the *second contact* the last trace of the sun's crescent disappears and the total phase begins. Within a few seconds all direct sunlight vanishes, it suddenly grows dark, the brightest stars become visible in the sky, and the dark disk of the moon is seen projected onto the pale mysterious halo of the sun's corona—an unforgettable spectacle. The general landscape illumination during totality is considerably brighter than on a night of full moon, but the sudden transition from daylight is most impressive.

Totally never lasts very long, $\frac{7}{8}$ minutes at the utmost. It ends at the *third contact* when the following limb of the moon begins to uncover the western rim of the sun. Daylight returns as suddenly as it vanished, the thin crescent of the sun gradually widens, and about $\frac{1}{2}$ hours later the second partial phase of the eclipse ends at the *fourth contact*, when the last encroachment made by the moon on the sun's rim disappears.

In a partial eclipse, see fig 2(B), the motion of the moon's disk is such that its centre does not pass across the centre of the sun. After the first contact the visible crescent of the sun decreases in width until the centres of the two disks reach their closest approach. This is the moment of maximum phase, and the latter is measured by the ratio between the smallest width of the crescent and the diameter of the sun. After maximum phase the crescent of the sun widens again until the moon passes out of the sun's disk at the last contact.

When observing a partial or annular eclipse it is necessary to protect the eyes against injury by the intense brilliance of the sun. The sun should be viewed only through a dark smoked glass (much darker than those of ordinary goggles) or a darkened photographic plate or film.

II. Eclipses of the Moon.—When the moon moves through the shadow of the earth (see fig 3), it loses its bright direct

illumination by the sun, although its disk still remains faintly visible. This phenomenon is called an eclipse of the moon. As the shadow of the earth is directed away from the sun, a lunar eclipse can occur only at the time of full moon, that is, when the position of the moon is opposite to that of the sun.

FIG 3—ECLIPSE OF THE MOON
The moon revolving in its orbit around the earth passes through the shadow of the earth U (umbra) is the total shadow P (penumbra) the partial shadow

To describe the progress of a *total eclipse of the moon* we draw a crosscut of the earth's shadow cone, both umbra and penumbra, at the distance of the moon as shown in fig 4. The moon's path relative to the shadow is indicated by the dotted line, and successive positions of the moon are marked by $M_1, M_2, M_3, M_4, M_5, M_6$. At M_1 the full moon enters the penumbra, and while it moves from M_1 to M_2 we have a penumbra eclipse. But the dimming of the moon's illumination by the penumbra is so slight as to be scarcely noticeable and penumbra eclipses are rarely watched.

After the moon has reached the position M_3 , a part of its surface is immersed in the umbra and is darkened, the moon is in partial eclipse. About an hour later the eclipse becomes total when (at M_4) the whole disk of the moon is within the umbra. However, the moon's surface is never completely darkened by an eclipse, even at the middle of totality it is visible with a peculiar dull ruddy hue. This illumination is caused by sunlight refracted in the earth's atmosphere and reddened by its passage through the air.

FIG 4—SUCCESSIVE PHASES OF A LUNAR ECLIPSE

The large circle of light shading is a crosscut of the penumbra at the distance of the moon. The smaller circle of dark shading a crosscut of the umbra. $M_1, M_2, M_3, M_4, M_5, M_6$ are successive positions of the moon as it crosses the shadow.

If the moon's path leads through the centre of the umbra the total eclipse lasts about $\frac{1}{2}$ hours. At M_4 the moon emerges from the umbra, we have again a partial eclipse ending at M_5 , followed by a penumbra eclipse ending at M_6 .

An eclipse of the moon is visible and presents the same features at all places on the earth where the moon is above the horizon. On account of the earth's atmosphere the edge of the umbra is rather diffuse, and the times of contact between the moon and the umbra cannot be observed accurately. The progress of a lunar eclipse can be adequately followed with the naked eye, with field glasses or a small telescope. It is an interesting experience for the layman but of little value for astronomical research.

III. Eclipses of the Satellites of Jupiter.—Eclipses of the four large satellites of Jupiter provide a frequent and fascinating spectacle to the telescopic observer. The orbits of these satellites lie nearly in the same plane as Jupiter's orbit around the sun, and at practically every revolution of each satellite the following four eclipse phenomena take place:

- (1) Eclipse of the satellite when it passes through Jupiter's shadow
- (2) Occultation of the satellite, when it disappears behind the planet as seen from the earth
- (3) Transit of the satellite across the disk of Jupiter
- (4) Transit of the shadow of the satellite across the planet's disk

Fig 5 illustrates the occurrence of these phenomena, it shows Jupiter and the orbit of one of its satellites, the direction of the sunlight illuminating the system, and the direction toward the earth from where the observation is made.

When the satellite in its revolution arrives at S_1 , it enters into Jupiter's shadow (eclipse) and vanishes from view of illumination. At S_2 it comes out of the shadow, but to the terrestrial observer it is now hidden behind the planet (occultation) until at S_3 it reappears at the limb. When the satellite reaches the position S_4 , its shadow falls on Jupiter causing a small dark spot on its surface. Seen from the earth the satellite is to the left of

FIG 5—ECLIPSES OF THE SATELLITES OF JUPITER

J represents the planet Jupiter. S_1 to S_7 mark successive positions of one of its satellites as it revolves in its orbit around Jupiter. The system is illuminated by sunlight from the left but is observed from the direction of the earth.

Jupiter approaching its limb, while at the same time its shadow spot passes across the planet's disk (transit of shadow). At S_5 the satellite starts to pass in front of the planet (transit of satellite) following its shadow spot. Since both Jupiter and the satellite turn their illuminated sides toward the earth, they differ little in surface brightness. Near the limb the satellite is somewhat brighter than the planet's surface on which it appears projected, but near the middle of the disk it is hardly distinguishable. At S_6 the shadow leaves the planet, and at S_7 the satellite emerges at the limb.

Historically the eclipses of Jupiter's satellites are important for they provided one of the earliest proofs of the finite velocity of light. It is possible to calculate with considerable precision the times of disappearance and reappearance of a satellite undergoing eclipse. Ole Roemer (1675) noticed discrepancies between the observed and calculated times which he explained as being the result of changes in the travel time of light when the earth is nearest to Jupiter or farther away from it.

IV Other Eclipse Phenomena—Occultations of Stars or Planets by the Moon.—From the earth we see the moon projected onto a background of distant stars. As the moon moves eastward across the constellations it will occasionally pass in front of one of the brighter stars, or of a planet, causing an occultation. At the moment when the eastern limb of the moon reaches a star, the latter suddenly disappears (immersion). In about an hour or less the moon will have passed over the star and the latter will reappear at the western limb (emersion). Between new moon and full moon the immersion takes place at the invisible (or faintly visible) dark limb, the emersion at the bright limb.

The surprising suddenness with which a star disappears or reappears without fading or flickering is conclusive proof that the moon has no appreciable atmosphere. Observations of occultations accurately timed are used to study the orbital motion of the moon.

Transits of Mercury and Venus.—The two planets Mercury and Venus, which are nearer to the sun than the earth, do some times pass between the earth and the sun. With a telescope properly equipped to reduce the overpowering light of the sun either of these planets is then seen as a small dark circular disk projected on the brilliant disk of the sun, crossing it slowly. The four contacts of the planet's disk with that of the sun are observed similarly as for a solar eclipse.

Transits of Mercury take place at irregular intervals of 3 to 20 years on an average 14 times per century. Transits of Venus are rarer, they have been of great astronomical importance for the accurate determination of the solar parallax. Many expeditions were organized to observe the transits of Venus of 1761, 1769, 1874, 1882, from distant places on the earth. The next transits of Venus will occur on June 8, 2004, and June 6, 2012.

Eclipsing binaries are stars which vary in brightness periodically. The most famous of these is Algol, or β Persei, the explanation of the light change is that there are two stars, not resolvable with the telescope, revolving round one another in an orbit whose plane nearly passes through the solar system. Thus one star passes periodically in front of or behind the other as seen from the earth, and two eclipses take place during each revolution. From the way in which the light from the double system varies it is possible to calculate the orbit and relative sizes of the two components, and to obtain certain other information (see STAR).

V Prediction and Calculation of Solar and Lunar Eclipses.—Our problem may be divided into two parts. The first seeks to find out when an eclipse will occur the other to determine its circumstances whether or not it is visible at a given place on the earth, its type (total or partial), etc.

It is convenient for our purpose to consider the earth as fixed and to suppose the observer situated at the centre of the earth. To this observer, O (fig 6), the sun and moon appear projected on the celestial sphere, a large sphere which he imagines surrounding him. While this sphere appears to him to rotate daily around the line PP' (the earth's axis of rotation), the sun's disk S appears to travel slowly along the great circle EE' (the ecliptic), making a complete revolution in one year. At the same time the moon's disk M revolves along the circle LL' once during a lunar month.

The angular diameters of the two disks S and M are about $\frac{1}{2}^\circ$, but vary slightly as explained in section I.

Every month the moon's disk M revolving along LL' will once overtake the more slowly moving sun S, this moment of overtaking is called the new moon. In general the moon's disk will pass above or below the sun's disk. Overlapping of the two disks results in an eclipse of the sun, it will occur only when the new moon happens at a moment when the sun is near the points Ω or Ω' , where the circle LL' intersects EE'. These points are called the ascending and descending nodes of the moon's orbit.

The moon will suffer an eclipse when it enters into the shadow cone of the earth. The crosscut of the umbra at the distance of the moon (as shown in fig 4) may be projected like a disk U onto the celestial sphere. It subtends an angle of about $1\frac{1}{2}^\circ$, its centre will always be opposite to the sun's disk and travel along EE'. An eclipse of the moon takes place whenever the moon's disk M overlaps the shadow disk U, this happens only when the shadow disk U is near one of the nodes, or the sun is near the opposite node. The passage of the sun through the lunar nodes is therefore the critical time for both solar and lunar eclipses. The moon's orbit plane, represented by the circle LL', is not fixed, and its nodes move slowly along the ecliptic in the direction indicated by the arrow, making a complete revolution in about 19 years. The interval between two successive passages of the sun through one of the nodes is termed an "eclipse year," since the moon's node moves so as to meet the advancing sun, this interval is about 186 days less than a tropical (or ordinary) year.

In fig 7(a) the region of the ascending node as seen from the centre of the sphere is much enlarged. Here the node is kept fixed and the apparent motions of the sun and the moon are taken relative to the node. To our imaginary observer at the centre of the earth the sun's disk S will travel along the circle EE', the moon's disk M along LL'. The sun is so distant compared with the size of the earth that from all places on the earth's surface the sun is seen nearly in the same position as from the centre

FIG 6—APPARENT MOTIONS OF SUN AND MOON ON THE CELESTIAL SPHERE

The observer O imagines himself at the centre of a large sphere. The sun S appears to move around the circle EE' (the ecliptic) once a year, the moon M around the circle LL', its orbit once a month. The crosscut U of the earth's shadow is always opposite to the sun S. The intersections (nodes) Ω and Ω' of the moon's orbit and the ecliptic revolve along the ecliptic once in 19 years.

But the moon is relatively near and its projected position on the celestial sphere is different for various observing stations on the earth, it may be displaced as much as 1° from the position in which it is seen from the centre of the earth. If we enlarge the radius of the moon's disk by 1° we obtain a circle C which encloses all possible positions of the moon's disk seen from anywhere on the earth. Conversely, if we draw any circle of the moon's

FIG 7—ASCENDING NODE OF THE MOON'S ORBIT AS SEEN FROM THE CENTRE OF THE SPHERE

- (a) A solar eclipse occurs somewhere on the earth whenever the circle C overlaps the sun's disk S. The circle C encloses all positions of the moon seen from anywhere on the earth at a given moment.
(b) A lunar eclipse occurs when the outcast U of the earth's shadow overlaps the moon's disk M.

size inside this "moon circle" C, there is a place on the earth where the moon is seen in that position.

Accordingly, there will be an eclipse of the sun somewhere on the earth whenever the moon overtakes the sun in such a position that the moon circle passes over the sun's disk, when the latter is entirely covered by the moon circle, the eclipse will be central (total or annular). From fig 7(a) it is evident that a solar eclipse will take place if a new moon occurs while the sun moves from S_1 to S_2 . This period is called the eclipse season, it starts 19 days before the sun passes a node and ends 19 days after. Since there is a new moon every month, at least one solar eclipse, and some times two, occur during every eclipse season. When the new moon falls within 11 days of the node passage (between S_2 and S_3), the eclipse will be central.

Fig 7(b) illustrates the condition for a lunar eclipse. If a full moon occurs within 13 days of a node passage of the sun (when the shadow disk passes the other node) the moon will be eclipsed. Most eclipse seasons, but not all, will thus also contain a lunar eclipse. Eclipses of the sun are evidently more frequent than those of the moon, but the former are only visible from a very limited region of the earth, the latter from a whole hemisphere. Any particular town or city would on the average experience about 40 lunar eclipses and 20 partial solar eclipses in 50 years, but only one total solar eclipse in 400 years.

The sun returns to the same node after each eclipse year, new moons (or full moons) recur at intervals of an ordinary month. Nineteen eclipse years (6585.7866 days) are nearly equal to 223 months (6585.3211 days). After this interval of 18 years 11 days, which is called the *saros*, the moon and the sun come nearly to the same relative positions again and eclipses will repeat themselves. Thus the solar eclipse of Sept. 10, 1923, was a repetition of that of Aug. 30, 1905. Already in ancient times the *saros* was used for the prediction of eclipses (see *Ancient Eclipses*, below).

Since the coincidence of the two periods is not exact, the repetition of an eclipse after a *saros* will be of different circumstances. Suppose an eclipse of the sun takes place while the sun is at S_2 (fig 7a) and the moon at M_2 , it will be visible on the earth in high northern latitudes from where the moon's disk is projected into the lower part of the moon circle. After 223 months there will be another new moon with eclipse. As this period is shorter by 0.4595 days than 19 eclipse years, the moon will now overtake the sun before the latter has quite returned to S_2 , while it is $28'$ farther to the right, nearer to the node. The sun will be closer to

the centre of the moon circle, and on the earth the eclipse will be visible nearer to the equator or farther south than the previous eclipse. After every *saros* the meeting of the moon and the sun will be a little farther to the right, until it takes place near S_3 , M_1 , after which the eclipse returns no more. Solar eclipses may thus be ordered into series, each of which contains 68 to 75 eclipses (about 18 total), at intervals of a *saros* extending over 13 to 14 centuries.

The fraction of 0.3211 days in the period of the *saros* has the effect of making each successive eclipse of a series visible about 110° of longitude farther west on the earth, and after three *saros* it returns nearly to the same longitude, but farther south if at the ascending node or farther north if at the descending node. Eclipses of the moon, of course, also occur in similar *saros* cycles.

During a solar eclipse the shadow cones (umbra and penumbra) of the moon sweep across the face of the earth (fig 1), while at the same time the earth is rotating around its axis. The circumstances of a solar eclipse are best illustrated by a map which shows the intersections of the shadow cones with the earth's surface and their tracks across continents and oceans resulting from the combined effects of both motions. Fig 8 illustrates the circumstances of the total solar eclipse of Nov. 1, 1948. The narrow double line marks the path along which the umbra travels in 34 hours from central Africa across the Indian Ocean toward New Zealand. Within the area of this lane, 50 mi wide, the eclipse is total. The wide surrounding region bounded by the full line is that covered by the penumbra, where the eclipse is partial. Within the lune at its extreme left the sun is already in partial eclipse when it rises, within the lune at the right the sun sets during the partial eclipse. In the intermediate region the whole progress of the partial eclipse can be observed, and from the dotted lines the time of its beginning and end at any particular place can be read.

The astronomical Ephemerides published for each year give such maps for the more important eclipses as well as data for accurate calculation of the times of contact at any observing station.

It is possible with the aid of modern tables to predict solar eclipses several years ahead with an accuracy of a few seconds. For predictions of longer range the main uncertainty is that of the moon's motion. Eclipses can, of course, be "predicted backwards" as well as forwards, and the calculation of ancient eclipses has been of value in historical research (see *Ancient Eclipses*).

(R. J. Tr.)

VI Phenomena and Information Yielded by Observation of Solar Eclipses—Partial solar eclipses give little information of astrophysical interest. Total eclipses, however, contribute much knowledge concerning the nature of the sun's external layers, regions that are usually lost in the brilliant sky glare from the sun's shining surface. Until fairly recently, these faint solar features were observable only at time of a total solar eclipse. A new instrument known as the coronagraph now facilitates the study of them outside of eclipse.

At total eclipse, the disk of the moon acts as a screen outside the earth's atmosphere, cutting off the direct rays from the "photosphere," as the bright solar surface is known. The brilliance of the sky is thus enormously decreased and the fainter appendages of the sun become visible.

The chromosphere (*q.v.*), the sun's atmosphere, extends upward from the photospheric surface, growing more and more rarefied with increasing height. The chromosphere has no well defined upper boundary, but it has been traced to a height of about 10,000 mi above the surface. It is filamentary in structure, being composed of myriads of streamers of luminous gas projected from the solar surface. An individual spall streamer, or spicule, is very short lived, from its beginning as a bright eruption on the surface until its fading out as a thin, faint, ribbonlike spurt, is a period of only 10 or 15 minutes.

The sun's atmosphere thus in no way resembles that of the earth. Not only is the structure of the chromosphere nonuniform, but the temperature is extremely high. Elements like iron, cal-

cium, or aluminum, which are solids on the earth, are completely vaporized on the sun and appear as important constituents of its gaseous envelope. The determination of the chemical composition of the atmosphere, and of the temperatures and pressures obtaining there, depends upon observations made at the time of total eclipse.

A spectroscope, consisting of a special arrangement of a narrow slit through which the light passes lenses to collimate and focus the radiation, and a prism or diffraction grating to disperse the light into its rainbow colours, is one of the most important tools that the astronomer possesses. At the time of eclipse the narrow solar crescent is often used in place of the customary spectrograph slit.

Each individual chemical substance—element or compound—when vaporized and heated to incandescence, sends out its own characteristic radiations. The exact colours emitted by iron differ completely from those sent out by hydrogen or calcium. Thus, when we watch the rainbow band of colours, or spectrum, of some unknown substance with the radiations from known substances, we can determine the chemical composition of the sample.

This procedure is the basis of modern spectroscopic analysis in the chemical laboratory. The astronomer applies it directly to the sun and stars. The relative intensities of the lines of a given element give further information concerning temperatures and pressures in the luminous material.

The ordinary spectrum of the sun contains a brilliant background of all colours—a so called continuous spectrum. This radiation emanates from the lower levels of the solar atmosphere where the pressure of atoms and electrons is high enough to inhibit the previously mentioned characteristic radiations. The atoms in the upper levels, however, absorb these radiations, so that the solar spectrum consists of the bright rainbow background, with many fine gaps where the light has been absorbed. These gaps appear as dark lines—absorption lines—on the bright background.

At the moment of totality, when the moon obliterates the last trace of the bright photosphere, with its dark line spectrum, the

upper, rarer layers of the atmosphere flash into view with the characteristic bright line spectrum of a luminous gas. This spectrum disappears within four or five seconds, as the moon moves over the sun and a second flash occurs at the end of totality. Because of its evanescent character, astronomers have called the phenomenon the "flash spectrum."

During totality there appears one of the most beautiful of nature's phenomena, the so called solar corona, which shines like finely etched white frost against the deep blue of the eclipse darkened sky. The form of the corona presented at different eclipses is almost infinitely variable. On occasion, usually near sun spot minimum, long streamers extend four or five solar diameters away from the sun. At other appearances, especially close to minimum, the corona is more nearly circular, but with jagged, flowerlike petals. The corona is faint, 500,000 times or so less brilliant than the sun itself. Consequently the ordinary sky glare surrounding the sun swamps the faint coronal glare. Until recently, astronomers considered it impossible to record the corona outside of eclipse.

Analysis of flash spectra has led to some surprising results. The spectrum matches only roughly with the dark line spectrum. The lines of the neutral metals are of comparable strength in the two spectra, but those of the ionized metals (μ , atoms that have lost one electron) are markedly enhanced in the flash spectrum. The difference is attributed, in part, to lower pressures in the upper layers, but elevated temperature appears to contribute to the increased excitation. Especially is this true for the flash lines of ionized helium, which do not appear at all in the ordinary dark-line spectrum. These require excitation temperatures of at least 25,000° K. for their production, where the temperature required to produce the observed quality and quantity of bright emission from the surface is only 6,000° K.

Extending upward from the chromosphere, and probably closely related to it, are the so called "prominences," which project outward into space occasionally as far as several hundred thousand miles. These objects are one of the striking features of a total eclipse. They appear as rose coloured patches of flame, projecting well beyond the limb of the moon. Despite the resemblance

to fire, prominences cannot be referred to as flames. They consist of long interlacing filaments of incandescent gas. Their rose colour arises from the predominant gaseous radiations, the red of hydrogen and the violet of ionized calcium. Prominences appear to have a temperature slightly in excess of that associated with the chromosphere.

The spectrohelograph (*qv*), invented independently by G. E. Hale and H. Deslandres, enabled astronomers to record the prominences outside of eclipse. Indeed, something of their form and structure is disclosed by an ordinary spectrograph, with the slit wide open. A special spectrohelograph, built at the McMath-Hulbert observatory, with motion-picture recording, was the first instrument to depict graphically the spectacular motions exhibited by some of the prominences. The objects often hang for days, suspended like clouds above the solar surface. Their internal motions are extremely complicated, a characteristic effect is the downward streaming of the filaments, which descend to the surface in long graceful arcs. Occasionally

FIG. 8.—MAP SHOWING THE SOLAR ECLIPSE OF NOV. 1, 1948

Within the narrow double line a total eclipse is observed. In the large area outlined the eclipse is partial. Reproduced from the American Ephemeris and Nautical Almanac by permission of the Nautical Almanac Office, U.S. Naval Observatory.

the great clouds will erupt with violent explosions and rapid motions. Velocities in excess of 100 mi. a second are not uncommon.

These motions, however, are not observable during the short duration of a total eclipse. The spectroheliograph or the instrument known as the coronagraph is required. The latter device, invented by B. Lyot, French astronomer, produces in effect an artificial eclipse of the sun inside the instrument. Under conditions of very clear sky, usually attainable only at high altitudes, astronomers can record the corona with some degree of regularity. The coronagraph was the solution of the problem of recording the corona outside the eclipse.

The corona presents many interesting problems, but the great est mystery of all—the nature of its composition—has been solved by B. Edlen, Swedish physicist. The spectroscope had revealed numerous lines, radiations that could not be matched with those from any known terrestrial element. For years astronomers theorized about "coronium"—a supposedly new element existing on the sun. There was precedent for such a hypothesis. At the eclipse of 1868, helium had been discovered in such a manner and was not isolated on earth until 27 years later, when Ramsay isolated it from gases extracted from radioactive ore. But as chemists filled in gap after gap in the periodic table of the elements, the hope faded of finding coronium as a new substance.

A somewhat similar mystery, that of the bright emissions from gaseous nebulae, was meanwhile solved by I. S. Bowen, who showed that the lines were due to "forbidden" atomic transitions. In other words, they arose from changes within the atom that were contrary to rules for normal lines. Under laboratory conditions these forbidden lines are extremely faint. Under conditions of low density, however, and special excitation, the normal radiations can be almost completely suppressed and the forbidden lines will then appear. Indeed, both nebular lines and coronal lines have been observed in the spectra of two variable stars of the recurrent nova class.

The coronal lines have also proved to result from forbidden transitions. But where the nebular atoms have lost but from two to four electrons, those responsible for the coronal radiations have had as many as 13 torn away. The substances identified are iron *X* (i.e., iron with nine electrons missing), iron *XI*, *XIII*, and *XIV*. Similar emissions from calcium and nickel also appear.

The import of this discovery is staggering—and almost unbelievable. Reference has already been made to the high excitation of the chromosphere and prominences, which led to estimates of temperature as great as 25,000° K. This figure is in itself enormous compared with the 6,000° K. value usually ascribed to the solar surface. But 25,000°, in turn, is insignificant compared with the minimum figure of 500,000° required for the observed ionization of the coronal atoms. Iron, with half its electrons removed, requires temperatures of at least this order of magnitude. Some estimates have been higher than 1,000,000°.

High temperatures of this character are difficult indeed to explain. They could not be induced by ordinary 6,000° radiation. No simple or reasonable solution to this new enigma of the corona had by 1946 been presented. But it seems that the answer is to be found deep in the solar interior, where even higher temperatures are known to exist. Somehow or other the highly excited matter must escape into space. The details of the process are still unknown.

There is a further implication from this new knowledge of the solar atmosphere. We can no longer assume that the solar radiation has a quality similar to that of a black body heated to 6,000° K. We must have in addition quantities of radiation in the far ultra-violet and even in the region of soft X rays, far in excess of that from an incandescent globe at 6,000°. These short wave radiations must enter the earth's upper atmosphere, where they cause the aurora borealis and produce the ionosphere, a high layer of electricity that is responsible for long-distance radio transmissions. But the atmosphere so completely absorbs these wave-lengths that none of the energy reaches the surface. We can learn of the existence of the radiation only from study of flash and coronal spectra and from evaluation of the effects in the earth's atmosphere. Variability of the earth's magnetic field is an

associated phenomenon.

The astrophysical value of eclipse observation is, perhaps decreasing. There are still some problems that can be solved only at a true eclipse—but the coronagraph and the artificial eclipse have many advantages. The superiority of the coronagraph lies in the fact that observations can be secured every clear day—whereas eclipses are relatively rare phenomena, usually occurring in distant and inaccessible locations. They last for only a few minutes—7½ minutes at maximum. The continuity thus provided shows that the corona is relatively stable in form, that it is not uniform in brilliance around the sun, and that it rotates with the solar surface.

Eclipse observations, in giving the astronomer answers to certain questions of the sun have nevertheless presented the scientist with newer and more puzzling problems. What relationship is there between the prominences and the corona? What is the source of their excitation? How are they related to sun spots and other solar features? Where does solar variability come into the picture? The questions can be multiplied *ad infinitum*. We must look to the future for the answers.

The Deflection of Light by a Gravitational Field—One of the most famous, and the first, of the tests of Einstein's theory of relativity was that of observing the bending of a ray of light passing close to the sun. During a total eclipse the brighter stars are visible to the naked eye and many more can be photographed near the sun.

Einstein's theory predicts that the stars near the sun should be found not in their true places but displaced away from the sun by a small, but measurable, amount varying inversely as the distance from the centre of the sun. This test was first carried out in 1919 and has been repeated since with results on the whole in favour of the theory (see RELATIVITY).

Other Phenomena—Baily's Beads—It is found that totality does not begin or end quite suddenly, as it should if the sun and moon were of perfectly smooth outline, but that there exists for a moment or two a crescent of minute gleaming points of light, called Baily's Beads. These are due to the irregular outline of the moon (i.e., its mountains and valleys), because of which the sun is left uncovered here and there for a moment after the disk representing the size of the moon, if smoothed out, would have covered it.

Shadow Bands—When totality is nearly due and there remains but a small crescent of the sun left there can often be seen on the ground or on the walls of buildings striations of light and shade, not very definite in outline but something like a sheet of corrugated iron, moving moderately rapidly perpendicular to their length. These are termed the shadow bands and are due to corrugations introduced into the nearly plane waves of light reaching us from the sun through irregularities in the refraction of the earth's atmosphere. They are of no great scientific import.

(D. H. M.)

VII. Total Solar Eclipses During The 20th Century—We omit those eclipses which are visible only in polar regions or are of excessively short duration. The first column gives the date of the eclipse, the next the duration of totality, the third the node near which the eclipse occurs and the number of the saros series to which it belongs, repeated eclipses having the same number. The last column states where the eclipse was or will be visible.

BIBLIOGRAPHY—S. A. Mitchell, *Eclipses of the Sun* (N.Y., 1923), a comprehensive popular account of the calculation and observation of eclipses, including description of the observations on theories of Solar Physics; F. J. M. Stratton, *Modern Eclipse Problems* (Oxford, 1927). *Nautical Almanac* (H.M. Stationery Office, ann.) Contains Besselian elements for all eclipses visible in the year and maps showing the paths of totality and times of beginning and ending, etc., of total eclipses. The issue for 1910 contains an account in detail of the method of computing the circumstances of an eclipse at a given place from the Besselian elements. In the *American Ephemeris, and Nautical Almanac*, a similar publication, the explanation of the calculation is given 3611b. *Canon der Finsternisse* T. R. Oppolzer, A catalogue with maps of all solar and lunar eclipses from 1207 B.C. to A.D. 2161, Vienna Acad. Science, vol. 52, Vienna 1887. See also W. M. Smart, *Text Book on Spherical Astronomy* (1944), chapter 15 outlines method of calculating occultations and eclipses.

ANCIENT ECLIPSES

It is not surprising that, in ancient times when eclipses were regarded as portents, a large number of eclipses should have been mentioned in history or in literature, in addition to those which are recorded in astronomical treatises or on astronomical tablets.

The value of these records may be classified as follows: (1) *Literary and historical*, depending on the interest which they aroused, the notice taken of them, and their connection with events; (2) *Chronological*, in so far as they enable us, by computing their dates, to verify chronological systems resting on other evidence and to supply dates for events connected with the eclipses; (3) *Astronomical*, including the determination by ancient astronomers of the periods and motions of the sun and moon, and by modern astronomers of the mean rate of change of those motions, which, in astronomical terminology, is called secular acceleration.

Literary and Historical References.—(1) *Chinese* In the *Shu King* or *Book of Historical Documents* it is stated that Hsi and Ho (the hereditary astronomers) had neglected the duties of their office and were abandoned to drink in their private cities. The king, Chung K'ang, placed the marquis of Yin in command of an army with instructions to punish them. The marquis issued a flood address to his troops in which he referred to Hsi and Ho having neither heard nor known anything on a recent occa-

sion when "the sun and moon did not meet harmoniously in Fang." The phrase is taken by all Chinese scholars, ancient and modern, to mean an eclipse. It would therefore appear that a military expedition was sent to punish the two astronomers for failing to observe an eclipse. There are good reasons for believing that this part of the *Shu King* is a literary restoration, made to take the place of books that were burned by imperial order in 213 B.C., but sufficient is found in a quotation made by Tso before that disaster and in the statements in the *Bamboo Annals* also made before that date, to prove that the reference to the eclipse is authentic, though its relation to the supposed offence of Hsi and Ho is doubtful. Attempts have been made to identify this eclipse, but the necessary data are wanting. It may easily have been a small eclipse, and the number of the month is given differently in different texts. The received Chinese chronology places the accession of Chung K'ang in 2159 B.C. The *Bamboo Books*, where chronology is probably nearer to the truth, place that event in 1952 B.C. The *Shih King*, or *Book of Poetry*, contains a lamentation caused by an eclipse of the moon, followed by an eclipse of the sun. The dates are clearly defined and are found to agree with the lunar eclipse of Aug. 21 and the solar eclipse of Sept. 6 in 776 B.C.

The eclipses recorded in the *Spring and Autumn Annals* possess a chronological and astronomical rather than a literary interest.

(2) *Assyrian*—The Assyrian eponym canon, which preserves the names of the annual magistrates who gave their names to the years, records under the year which corresponds to our 763-762 B.C.—"Insurrection in the city of Assur. In the month Sivan the sun was eclipsed." The reference must be to the eclipse of the sun on June 15 in 763 B.C. A reference to the same eclipse has been found in Amos viii, 9, "And it shall come to pass in that day, saith the Lord God, that I will cause the sun to go down at noon, and I will darken the earth in the clear day."

(3) *Greek*—In the *Odyssey* Homer twice makes the unrecognized *Odysseus* predict that *Odysseus* will return "as the old moon wanes, and the new appears," that is, at new moon, when alone an eclipse of the sun is possible. In one of these passages he predicts vengeance on his wife's suitors. On the day when *Odysseus* was to become known and slay the suitors, the seer *Theoclymenus* notes among other portents of gloom that "the sun has perished out of heaven, and an evil mist has spread over all." This was interpreted by *Plutarch* and *Eustathius* as a total eclipse of the sun. Some modern scholars have regarded it as merely a vision of the seer *Schoch* (the *Observatory*, xlix [1926] pp. 19-21) has suggested an identification with the solar eclipse of April 16 in 1178 B.C., which was total in or near *Ithaca*. But it is not improbable that the story of the eclipse belongs to legend rather than to history.

In a fragment of a lost poem by *Archilochus* occur the words "Nothing there is beyond hope, nothing that can be sworn impossible, nothing wonderful, since *Zeus*, father of the *Olympians*, made night from mid-day, hiding the light of the shining sun, and sore fear came upon men." According to *Aristotle* the words come from a passage, abusing a lady, probably *Archilochus's* former *fiancée* *Neobule*, who is supposed to have belonged to *Paros*. The life of *Archilochus* was divided between *Paros* and *Thasos*. The phenomenon described has been identified as the total eclipse of the sun on April 6 in 648 B.C.

Small fragments survive of other poetic descriptions of eclipses, and the ninth paean of *Pindar*, addressed to the *Thebans*, takes an eclipse of the sun as its theme. *Sandys* translates the opening lines as follows:

"Beam of the sun! O thou that seest afar, what wilt thou be devising? O mother of mine eyes! O star supreme, reft from us in the daytime! Why hast thou obliterated the power of man and the way of wisdom, by rushing forth on a darksome track?"

Pindar then proceeds to speculate on the meaning of the eclipse as a portent. The poem probably refers to the solar eclipse of 463 B.C., April 30, which was nearly total at *Thebes*.

The most famous of ancient eclipses was a total eclipse of the sun which happened according to *Herodotus* during a battle between the *Lydians* and *Medes*. The portent induced them to cease from fighting and conclude peace. *Herodotus* further informs us that *Thales* of *Miletus* predicted this eclipse to the *Ionians* for the very year in which it happened. *Babylonians* were certainly predicting eclipses about this time by means of the 18 years' cycle known as the *Saros*. But, as that cycle gives eclipses for every year, the statement about *Thales* must if true mean that he predicted that an eclipse of the particular year would attain a great magnitude. Such a prediction can be made by the 18 years' cycle without any mathematical computation. The eclipse was certainly that of 585 B.C., May 28, and must have been predicted by means of the eclipse of 603 B.C., May 18. Several ancient writers have preserved 585 B.C. or some neighbouring year as the date of the eclipse.

Thucydides comments on the frequency of eclipses during the *Peloponnesian war*. The most interesting of these were the solar eclipse of 431 B.C., Aug. 3, when, we are told, "the sun assumed the shape of a crescent and became full again, and during the eclipse some stars became visible," a statement that agrees well with modern computation, and the lunar eclipse of 413 B.C., Aug. 27. That date had been selected by the Athenian commanders, *Nicias* and *Demosthenes*, for the departure of their armament from *Syracuse*. All preparations were ready, but the signal had not been given, when the moon was eclipsed. The soldiers and sailors clamoured against departure and *Nicias* in obedience to

the soothsayers resolved to remain thrice nine days. This delay enabled the *Syracusans* to capture or destroy the whole of the Athenian fleet and army.

The year 310 B.C., Aug. 15, is the date of a total eclipse of the sun, which, as we are informed by *Diodorus* and *Justin*, was seen by *Agathocles* and his men the day after he had sailed from *Syracuse* on his way to *Africa*. Modern computations of the eclipse track render it probable that he sailed to the north of *Sicily*.

In *Plutarch's* *Dialogue on the Face which appears in the Orb of the Moon*, one of the characters, called *Lucius*, deduces from the phases of the moon and the phenomena of eclipses a similarity between the earth and the moon and illustrates his argument by means of a recent eclipse of the sun, "which, beginning just after noon, showed us plainly many stars in all parts of the heavens, and produced a chill in the temperature like that of twilight." A little further on *Lucius* refers to a certain brightness which appears round the moon's rim in total eclipses of the sun. *Nicolaus Struyck* identified this eclipse with that of A.D. 71, March 20, and the identification has been confirmed by *Ginzler* after a very exhaustive discussion. There are numerous other references to eclipses in Greek literature.

(4) *Roman*—There is a very large number of eclipses recorded in Roman history. One which has attracted the attention of students alike of astronomy and of the Roman calendar is stated by *Cicero* to have occurred in the 350th year from the foundation of *Rome* and to have been described by the poet *Ennius* as follows: "On the Nones of June the sun was covered by the moon and night." This would appear to have been the solar eclipse of 400 B.C., June 21, which reached a total or almost total phase at *Rome* a few minutes after sunset. It seems to show that in that year the calendar month of June began 16 days later than in the calendar as reformed by *Julius Caesar*.

The eclipse of the moon in 168 B.C., June 21, has attracted much attention. *The Romans* were at that time at war with *Macedon*, and *Polybius* informs us that the eclipse of the moon was interpreted as an omen of the eclipse of a king and thus encouraged the *Romans* and discouraged the *Macedonians*.

Use of Eclipses for Chronological Purposes—Although no continuous era has been used since ancient times, dates are frequently expressed in terms of regnal years, or are named after consuls or other officials of whom lists have been preserved. In these cases it is important to be able to equate certain specific years thus defined with years before the Christian era. This can be done whenever the date of an eclipse or other identifiable and calculable astronomical phenomenon is given in an ancient record.

The received Chinese chronology can be confirmed accurately by eclipses from 719 B.C. onwards. The chronology of *Ptolemy's* canon of kings, which gives the *Babylonian* series from 747 to 539 B.C., the *Persian* series from 538 to 324 B.C., the *Alexandrian* series from 323 to 30 B.C., and the *Roman* series from 30 B.C. onwards, is confirmed throughout by eclipses. The eclipse of 763 B.C., recorded in the eponym canon, enables us to carry the chronology back with certainty through the period covered by that canon, to 803 B.C. *Assyrian*, *Babylonian* and *Persian* chronology provide a stable chronology for the countries with which *Assyria*, *Babylon* and *Persia* came into contact, but there is no check from eclipses on *Greek* or *Egyptian* historical chronology before the *Persian* period. Identifiable eclipses recorded under named *Roman* consuls extend back to 217 B.C. The dated eclipses of *Ennius* and *Pydna* and one in 190 B.C. can be used to determine the position of *Roman* calendar months in the natural year, and occasionally eclipses help us to fix the precise dates of a series of events, such as those connected with the Athenian disaster at *Syracuse*.

Use of Eclipses for Astronomical Purposes—(1) *In Ancient Astronomy*. It would appear that at least from the time of *King Nabonassar* (747 B.C.) a dated canon of astronomical observations was preserved at *Babylon*, including all eclipses. This rendered it possible to determine accurately the intervals between eclipses and must have facilitated the discovery of the 18 years' cycle, more exactly the cycle of 6,585½ days, which *Suidas* calls the *saros* and its multiple, the 54 years' cycle of 19,756 days.

These cycles govern the recurrence of eclipses. It has been seen that Thales probably used such a cycle. In a Babylonian observation tablet of 568 B.C. mention is made of future to observe a predicted eclipse of the moon. The eclipse is found by computation to have been real, but invisible at Babylon. It was doubtless predicted by cycle. Tables based on the saros go back to the 4th century B.C. Eclipses of the moon give more accurately than any other kind of observation the actual time when sun and moon are in opposition. From an early date the Babylonian astronomers must have deduced from them not only the mean interval between two conjunctions, but the principal inequality in the motion of the moon and the similar inequality in the motion of the earth, or, as on their geocentric theory they conceived it, of the sun, and they were able to define the periods of these inequalities, which astronomers call the anomalistic month and year.

In the same way, since eclipses happen only when the two luminaries are situated at intersections of their orbits called nodes, and since the path of the shadow in a lunar eclipse depends on the position of the centre of the sun in relation to the node, they were also able to determine the position and motion of the nodes. By assuming, what is approximately true, that the saros of 6,585½ days contained an exact number (a) of synodic months, or revolutions of the moon measured from the sun, (b) of anomalistic months, or revolutions of the moon measured from her apogee or perigee, that is, from her furthest removal from and closest approach to the earth, and (c) of draconic months or revolutions of the moon measured from her node, the early astronomers, perhaps in the 6th century B.C., computed the relative motions of the sun and moon, the lunar perigee and apogee, and the nodes. About 500 B.C. Naburannu, apparently from a more accurate study of eclipse observations, obtained improved values which for the motion of the moon from the sun were 10" per annum too small, for the moon from her perigee 20" per annum too great, and for the moon from her node 5" too small. Still more accurate values were obtained by Kidinnu about 383 B.C., from whom they passed to the Greek astronomer Hipparchus. In the system of Naburannu the distance of the moon from her node was used for the prediction of the magnitude of lunar eclipses.

(2) *In Modern Astronomy*—Ancient eclipses are of the highest value for the determination of "secular accelerations," that is, for the determination of the progressive, as distinct from the periodic, changes in celestial motions. Edmund Halley asserted in 1695 his belief that the moon's motion was subject to acceleration, but did not specify the amount of the acceleration. In 1749 Richard Dunthorne demonstrated from a comparison of the recorded with the computed times of eclipses distributed over 3,000 years that such an acceleration existed and assigned to it the value of 10" a century. By this is meant that the effect of the acceleration is to produce an advance of 10" in the moon's longitude in the course of a century. Laplace in 1786 discovered that such an acceleration should be the gravitational effect of the secular diminution in the eccentricity of the earth's orbit. But J. C. Adams showed in 1853 that the acceleration due to this cause amounts to 6" only in a century. The residue must be explained by other causes.

The most recent values are 11" a century acceleration of the moon, of which 5" is unexplained, and about 15" a century for an acceleration of the earth's motion suggested by P. H. Cowell in 1905. It is usual to regard the latter as an apparent effect of a retardation of the earth's rotation, which is our standard of time. This should produce an apparent acceleration of the Moon 13.4 times as great as that of the earth. But, since the unexplained acceleration of the moon is only about 3.3 times as great as that of the earth, it becomes necessary to suppose that there is a real secular retardation of about 15" a century in the moon's motion. It is commonly supposed that tidal friction is the main cause of both retardations. (See MOON.)

BIBLIOGRAPHY—J. J. Fotheringham, *Historical Eclipses* (1921), and "A Solution of Ancient Eclipses of the Sun," *Monthly Notices of the Royal Astronomical Society*, lxxxi (1920), 104-126. Fr. Boll, *Le Paganisme*, Paris-Wissembourg, Realencyklopädie, vi (1909), 2129-64,

with a list of recorded eclipses. O. Neugebauer, "The History of Ancient Astronomy Problems and Methods," *Journal of Near Eastern Studies*, iv (1945), 1-38. An excellent summary of the state of the history of ancient astronomy, without special emphasis on eclipses. An extensive bibliography is included. (J. K. F.)

ECLIPTIC, in astronomy is the great circle on the celestial sphere which forms the apparent path of the sun in the course of the year. The twelve constellations or signs of the zodiac are arranged along the ecliptic. The plane of the ecliptic is the plane of the earth's orbit, or more strictly the plane in which the centre of gravity of the earth and moon revolves round the sun, it meets the celestial sphere in the great circle above mentioned.

ECLOGITE, in petrology a typical member of a small group of rocks now recognized as including both igneous and metamorphic representatives, and of special interest on account of the variety of minerals they contain and their geological relationships. The eclogites (from Gr. *ἐκλογή*, a selection) are mostly coarse grained and massive aggregates of green monochlorite pyroxene and red garnet, but some varieties possess green hornblende wholly or partly replacing the pyroxene, thus giving rise to the two important groups—the pyroxene and the hornblende eclogites. The minerals associated with these essential constituents include rutile, apatite and iron ores, and, less commonly, quartz, muscovite, zoisite, cyanite, albite, bronzite, olivine and chlorite. The eclogites correspond closely in bulk composition with the gabbros and dolerites, but are characteristically assemblages with high density (3.2-3.6 as compared with gabbro 2.9-3.0).

The pyroxenes show considerable variation in composition, and include both non-aluminous and aluminous varieties. The latter contain significant proportions of the jadeite and aegirine molecules and correspond to true omphacite. The red garnet is a pyroxene-rich variety containing almandine and grossular, but is not so magnesia-rich as the garnet found in serpentines and peridotites. The hornblende is usually a green variety—smaragdite, or alkali-hornblende sometimes approaching glaucophane in composition.

Whether of metamorphic origin or considered as igneous rocks consolidating under excessive pressures, the almost complete absence of plagioclase feldspar makes these rocks of peculiar interest. The omphacite garnet assemblages appear to have crystallized under high pressures, in place of augite, olivine and plagioclase. Magnesian garnet appears in place of the olivine-anorthite pair, and a jadeite-chloromelanite-bearing pyroxene in place of the augite plagioclase combination of the heteromorphous gabbros.

Under the name griquaites, eclogites are found as blocks or boulders in the kimberlite "pipes" of the diamond fields of South Africa. This pyroxene-eclogite is of special interest inasmuch as diamonds have been found as enclosures of the garnet of the rock, and according to one prevailing view eclogite is the parent rock of the diamonds of the South African fields, the diamonds of the "pipes" being derived from the explosive disruption of deep seated masses of diamantiferous griquaites.

That some eclogites are of metamorphic origin is clearly revealed by their geological associations and microscopic structures. Such often appear as lenses intercalated among crystalline schists and show unmistakable crystalloblastic structures.

Others, such as those of western Norway occur as lenticular masses in granite gneiss or bands in olivine rocks (peridotites, dunites or their serpentine derivatives). These rocks possess no true crystalloblastic structure, and are believed to be unaltered igneous rocks. Probably some eclogites from other areas previously believed to be transmutated gabbros are of similar origin.

The amphiboles of the eclogites may represent either a direct crystallization from the magma, or arise by metamorphic processes from original pyroxene, and it is not improbable that many of the so-called "garnet amphibolites" of archæan tracts are transformed eclogites. The recognition of eclogites as primary magmatic consolidations under high pressures has led to the conception of an eclogite zone in the earth's crust immediately below the more acid and silicate shell. At depth magma of basaltic or gabbroid composition may exist stable as solid eclogite, and

it is possible that in this zone is to be discovered the source of the eclogite blocks of the Kimberlite "pipes." Research revealed that the geological associations of some eclogites appear not to accord with the prevailing conception of the group as a high pressure mineral facies. In a seemingly anomalous environment are certain eclogites and, indeed, the mineral jadeite itself, found in intimate association with low-grade metamorphic schists or serpentines, in France, California and the Celebes.

Though some of these associations may be the result of tectonic transport, there remain occurrences to which such an interpretation is inapplicable.

The chief localities for eclogites are archaean and palaeozoic metamorphic igneous complexes. They are known from Scotland, western Norway, Saxony, Bavaria, the Alps, Austria, Greece and California.

(C. E. T.)

ECLOGUE, a short pastoral dialogue in verse. The word is conjectured to be derived from the Greek verb ἐκλογέω, "to choose." Another derivation traces it to αἶψ, "goat," and λόγος, "speech," and makes it a conversation of shepherds. The idea of dialogue, however, is not necessary for an eclogue, which is often not to be distinguished from the idyll.

The grammarians, in giving this title to Virgil's pastoral conversations (*Bucolica*), tended to make the term eclogue apply exclusively to dialogue. The eclogues of the Spanish poet Garcilasso de la Vega (1503-36) are still admired. (See also *BUCOLICS*, *PASTORAL*.)

ECOLOGY, ANIMAL, is concerned with the interrelations between animals and their environments. It is a subdivision of the science of ecology, or that branch of biology which embraces the interrelations between plants and animals and their complete environments. Ecology is a basic approach to the conservation of natural resources and—together with several other biological sciences, such as biochemistry, genetics, cytology and general physiology—cuts across the sciences of zoology and botany. That is, it is concerned frequently with general principles that apply to both animals and plants.

The content of ecology may be divided in several ways. First, where attention is directed to the type of environment, ecology is divisible into terrestrial interrelations (terrestrial ecology), fresh water interrelations (biological content of limnology) and marine interrelations (biological content of oceanography). Second, where emphasis is upon plants or animals, we speak of plant or animal ecology. Third, where the point of departure deals with the level of the complexity of interrelations, we have to do with autecology, or the interrelations of the individual plant or animal with its physical and biotic environments, or with synecology, which is the study of progressively complex interrelations of natural assemblages of organisms, such as populations and communities.

These groups of ecological categories are seldom wholly separable. They are united both by the application of common principles and by natural intergradations between any two. For example, fresh-water marshes merge with grassland or forest, areas may be covered with a temporary pond at a particular season of the year, river mouth and the sea meet at the estuary. A complete understanding of an animal is impossible without considering its relationships with plants. Similarly, such an understanding is not possible without considering its interrelations with others of the same kind and animals of different kinds. Consequently, the study of the entire natural assemblage of plants and animals and their environment is desirable in any investigation that aims at completeness.

The technique of ecology is both experimental and descriptive. The science has many important interrelations with other branches of basic and applied knowledge. Several examples are notable.

In basic biology one such problem is that of the origin and establishment of species. When a new species arises, its particular adjustments of structure, function and behaviour must be such that the population may live in a particular environment or series of environments. It must adjust both to the physical influences that are in operation and to biological factors already established. Under such conditions the new population may do one of three things. It may adjust to the total environment, it may emigrate

to another environment, it may die. If the organisms adjust, this implies that they can compete or co-operate with other species for food and shelter. Consequently, the establishment of a species is the result of ecological selection of a particular heredity.

Interrelations between ecology and sociology were summarized by J. W. Bews (1935).

There are many ecological aspects of man's industrial and agricultural production. These include the relations of economic plants to soil types, diets of farm and range animals, pollution, overfishing, overgrazing, overcultivation, dust storms, floods, forest fires and game conservation. Often a man-made catastrophe has its origin in the unconscious application of ecologically unsound practices. For additional information the summaries of P. B. Sears (1935) and J. N. Gabrielson (1941) may be consulted.

The importance of general conservation, whether of oil and coal or of timber, soil, migratory birds or whales, cannot be emphasized too much with reference to the future well-being of mankind. Plants and animals are interrelated in highly complex natural communities and they must be manipulated or replaced with scientific care. Here the application of ecological principles ranges from those involved in the stocking of a small lake to a national program of reforestation. Basic research and the training of personnel should precede attempts at conservation since the solution may require answers to a number of inconspicuous yet important questions. For example, the bighorn or Rocky Mountain sheep formerly ranged over high mountains from Arizona into British Columbia and Alberta but is now absent or present only in reduced numbers in many parts of that territory. Herd reduction may be a consequence of many adverse influences, including (1) shooting of bighorn by hunters, (2) insufficient forage plants, (3) inadequate range, (4) scarcity of water, (5) disease, (6) poisons, (7) competition for food with domestic cattle, (8) competition for food with other game such as mule deer, (9) predation by such hunters as the bobcat and puma.

It will be seen that ecology has many interrelations with other branches of learning and that its applications are inextricably involved with man's destiny. As information accumulates in regard to the requirements of species populations and community relations, such data become available to animal husbandry, agriculture, conservation and public health. The danger is that the information will not be available in an integrated form soon enough to ensure broad conservation of natural resources.

Solution of many problems in public health and medicine involve ecology. Thus, the effective control of a variety of diseases is achieved by control of the vector rather than by the control of the disease-producing agent or pathogen. Such vectors include malarial mosquitoes, mosquitoes carrying the virus of yellow fever and jungle yellow fever, rats and rat fleas infected with plague bacteria, ticks and mites carrying pathogens responsible for such diseases as certain relapsing fevers, forms of typhus and many more. Control of the carrier is an ecological problem since the program involves the interrelations of the vector with its environment.

BASIC REQUIREMENTS OF ANIMALS

Organisms have three basic physiological requirements to meet if they are to live as individuals and perpetuate the species. These drives are nourishment, recuperation and reproduction. Their ecological counterparts are food, shelter and certain problems involving territory. The particular ways in which species satisfy these drives involve modification of structure, functions and behaviour that are known as adaptations or adjustments. The better adjusted the organism the better its chances of living with other members of its species population and with members of other species populations. Consequently, there are recognized three general categories of adjustments: feeding, sheltering and reproductive.

Food—Starting with the problem of food, organisms must obtain nourishment to live, and, since food must be obtained from the environment, it becomes a fundamental ecological factor. Certain basic aspects of plant nourishment are discussed in the treatment of communities. A survey of feeding adjustments among animals is appropriate here. As a rule, the food types that

make up the bulk of a species' diet are associated with definite feeding adjustments. The first feeding category is that of plant eaters, or herbivores. There are many kinds of these and only a few examples can be mentioned. Numerous insects such as aphids, feed upon plant sap, and their mouth parts are in the form of a tubular, sucking beak. Other insects including certain ants, have thick crushing jaws for cracking seeds. Although lizards as a group are meat eaters, some species eat vegetation and have rounded and broadened teeth. Among mammals the domestic cow and horse, as well as the deer, have some teeth flattened for grinding their food.

The second feeding category is that of the carnivores, or flesh eaters. Within this group there are two subdivisions. The first of these are the predators. These stalk their food and kill by direct assault and then feed upon the victim. Their adjustments are for overtaking and holding prey. Here may be mentioned the long highly modified mouth parts that enable cycloid ground beetles to feed on certain snails while the latter are withdrawn into their shells, the sharp claws of cats, the recurved teeth of the black snake, and the protrusible tongue of the toad. The second group of carnivores contains the parasites. These differ from predators in that they feed on the flesh of their prey, the host, while it is vigorous and at liberty, whereas predators feed after their prey has been subdued and is dead or dying. It is to the biological advantage of parasites that the host is not killed. Here are numerous types of feeding adjustments, including ectoparasites and entoparasites, living on or within the host's body, respectively. An entire branch of biology, parasitology (*q.v.*), is concerned with these animals. Many parasites are adjusted to feed on a special kind of food. The blood diet is such a particular case, and feeders on blood are known as sanguivores. Such animals generally have specialized saliva that is anticoagulant and anaesthetic in its action. Common sanguivores are fleas, the majority of female mosquitoes, bedbugs, leeches and ticks. Common entoparasites include the tapeworms and flukes.

Then there are the omnivores, feeding on a variety of both plants and animals. Man is an omnivore, and his dentition enables him both to cut and grind his food. There are many aquatic omnivores and the majority of these feed on minute organisms in the water and consequently must be collected by specialized conveying and straining mechanisms. Whalebone whales, rotifers, sponges, numerous marine worms, clams, oysters and barnacles collect and devour minute, usually floating, often microscopic plants and animals in the water. Obviously, within and between these three major feeding categories there are many differentiations and intergradations.

Shelter—Turning to the second of three basic organismal drives, it is found that continuous physiological activity leads to exhaustion and finally death. Therefore, animals must undergo physiological recuperation or rest. Frequently this is accomplished during sleep or its physiological equivalent. In animals such resting periods, with their relative inactivity and relatively slower responses to external stimuli, are dangerous since the individual is more exposed to attack from its natural enemies. Consequently, the majority of animals undergo periodic rest in some protected or sheltered spot, such as the mud on the bottom of a pond, a hollow tree, beneath a log, in a subterranean burrow, or beneath a leaf or deep within a flower. These homes are known as habitat niches. They are restricted portions of larger areas known as habitats.

Habitats—Habitats may be classified as follows

- I Habitats occupied by free living organisms
 - A Salt water or marine (polar, temperate, tropical)
 - 1 Littoral or shore
 - a Rocky
 - b Sandy
 - c Muddy
 - 2 Pelagic or surface waters of seas
 - a Abyssal or deep sea
 - B Brackish water, such as an estuary
 - C Salt lakes, such as the Dead sea of Palestine and Great Salt Lake of Utah
 - D Fresh water
 - 1 Standing water

- a Marsh
- b Bog
- c Ponds and lakes (polar, temperate, tropical)
 - (1) Perennial, or fresh-water littoral
 - (2) Intermittent, or fresh water "pelagic"
 - (3) Profundal, or deep-water, and pedonitic, or lake-bottom
- a Flowing water
- a Springs
 - (1) Cold-water
 - (2) Thermal, or hot-water
 - (3) Chemical, such as sulphur springs
- b Streams (including small brooklets and large rivers)
 - (1) Rapids or waterfalls
 - (2) Relatively quiet pools
- E Terrestrial
 - 1 Epigeal, or aboveground
 - a Flood plains
 - (1) Gravel
 - (2) Sand
 - (3) Silt
 - b Grasslands
 - (1) Tall grass
 - (2) Short grass
 - c Forests
 - (1) Deciduous
 - (2) Evergreen
 - (a) Tropical
 - (b) Coniferous
 - d Desert
 - (1) Sandy
 - (2) Rocky
 - e Ice desert
 - 2 Hypogeal, or subterranean, such as caves

II Habitats occupied by parasites

A Ectoparasitic

B Entoparasitic

This general classification can be expanded almost indefinitely. For example, the societies of ants, termites, certain wasps and bees and the towns and cities of man are habitats to a great array of plants and animals. Again, each category in the above list is subject to considerable variation with respect to latitude, altitude and the differential action of numerous environmental influences. Obviously there are many intergradations between habitats, too numerous to list. For example, grassland and desert intergrade in semidesert, a shore may consist of sandy mud, or a pond may be present only during the spring months.

A habitat may be occupied continuously by the same animals, termed permanent residents, or occupied at a particular period by animals known as temporary residents. Within an American elm and oak deciduous forest chipmunks are permanent residents whereas the migratory black and white warblers are temporary residents.

Many permanent residents undergo special periodic sheltering adjustments associated with dormancy. One of the adjustments associated with winter is termed hibernation (*q.v.*). It is accompanied by a relatively low temperature and physiologically inaccessible water in the form of snow and ice and the habitat niche is termed a hibernaculum. One of the adjustments associated with summer is termed aestivation. It is accompanied by a relatively high temperature and physically inaccessible water or drought, and the habitat niche is termed an aestivaculum.

Hibernation and aestivation are broad seasonal adjustments. There are many sheltering adjustments of a more limited nature. A familiar example is the periodic occupation of habitat niches for a part of each 24 hr cycle of day and night. Often the same niche is occupied by different populations at different times. Many nocturnal animals inhabit the carpet of decomposing leaves of a forest by day and feed on the living foliage of the trees during parts of the night, their ecological counterpart, the diurnal animals, are active by day and inactive during the night, and many of these pass their period of rest in the same layer of leaf mould.

It must also be remembered that often the several stages in the life cycle of an animal occupy a series of different habitat niches and often a series of different habitats. For example, the minute young of the common fresh-water clams are known as glochidia and, when discharged by the parent, have a brief period in the water of the stream or lake during which time they must become attached to fishes to live. If they can attach to a fish, they become

parasitic for a time and are dispersed in this manner. Eventually they leave the host, settle to the bottom and become free living clams. Again, the familiar May flies, stone flies and dragon flies hatch from eggs laid in fresh water, lead herbivorous or carnivorous aquatic lives as naiads and then transform into aerial adult insects.

Members of a particular kind of animal, a species, tend to have common structural, functional and behavioural adjustments, and consequently the population occupies a series of similar habitat niches throughout the range of the species. These niches may be identical, or ecologically equivalent if the range is great or the species is tolerant of a variety of conditions and habitats. This ability to tolerate environmental variations is known as vagility. The puma, with a range from sea level to high elevations in mountain ranges, and from Alaska to Patagonia, has a high vagility, sloths, restricted to certain kinds of tropical American forests, have low vagility.

The environment is constantly selecting the inherited adjustments of animals, and animals are constantly modifying their environment through feeding, burrowing, respiration, depositing their faeces and excreta and eventually their bodies. Consequently, through long periods of time, populations evolve with better adjustments to existing conditions through natural selection, and the habitats and habitat niches change through the influence of physical and biological factors.

In this almost constant process of change, the species that inhabit the same habitat compete for food and shelter and often co-operate for these necessities. Such competitions and co-operations are both direct and indirect, and their proper study is a vast subject (see POPULATION ECOLOGY). The sheltering adjustments that allow a species to inhabit several habitat niches over its life history is such a large subject that a few examples must suffice.

In the first place, there are the broadest levels of adjustment to media, for example, aerial, aquatic and terrestrial adjustments for locomotion as well as respiration in air or water, and within the watery medium, more specialized adaptations for life in the relatively fresh waters of inland lakes and streams in contrast with a life in the salt water of oceans. Within these broad adjustments there are progressively more specialized features that allow a species to inhabit a particular habitat and even live in a particular portion of its habitat.

Stream animals illustrate this process. They are adjusted to the whole stream in a general way, but some species (fishes, May-fly naiads) obtain their oxygen through gills while others (dytiscid beetles) carry a supply of fresh air when they dive and periodically replenish their supply by returning to the surface. Furthermore, certain types of animals tend to inhabit quiet pools, where the current is relatively slow and the amount of dissolved oxygen relatively small, whereas others tend to inhabit rapids, where the current is swift and the dissolved oxygen abundant. Consequently, there are pool mores and rapids mores indicating that such animals have a collective type of adjustment to a special portion of the stream.

Then there are still more special adjustments to a part of such a habitat. For example, there are adjustments to the surface film of the water. Water striders (Gerridae) skate over the surface on their setose tarsi. Certain species of the staphylinid beetle genus *Stenus* have an anal secretion that lowers the surface tension of the water, and the greater tension of the film on which the anterior parts of the beetle rest tends to pull the insect rapidly forward. Still others, such as the larvae and pupae of mosquitoes, lie just beneath the water surface, and the contact of the film with certain parts of their bodies supports them without expenditure of muscular energy.

Since most aquatic animals are heavier than water, those that inhabit the upper layers, rather than move over the bottom, must hold their spatial position against the pull of gravity. Such buoyancy or flotation adjustments are typically diverse. The swim bladder of many fishes aids in this maintenance of position. Many minute single celled animals or Protozoa achieve buoyancy by the presence of oil globules in their protoplasm. Certain

marine snails have egg masses that are kept afloat by a mucous pad that is infiltrated with air bubbles. One marine group of protozoans, the Radiolarians, has a dense skeleton of silicon yet lives near the sea surface. In certain radiolarians this is accomplished by the secretion of carbon dioxide that accumulates as gas bubbles in their protoplasm. Numerous surface dwellers, including some rotifers many small crustaceans of the order Cladocera and protozoans of the genus *Ceratium*, undergo a seasonal change in form in apparent correlation with the density and viscosity of the water. The warmer water of summer offers less resistance to sinking. The summer populations of these animals have the surface expanded in proportion to their mass, whereas the winter populations have a relatively compact form with fewer or shorter projections.

From what has been said it is apparent that the study of habitats and habitat adjustment is as broad in scope as the study of ecology. Over long periods of time most organisms other than man are chiefly responsible for the formation of a rich, organic soil. Activities of civilized man usually lead to strong modifications of habitats, for example, the pollution of streams and lakes, soil erosion, destruction of watersheds and dense smoke clouds are but a few ways in which habitats deteriorate.

Reproduction.—Another basic drive, reproduction, has many ecological implications. Climate and weather have both long-range effects and more immediate effects upon such diverse aspects as courtship behaviour, time of mating, laying of eggs and development of the larval or immature stages. Most higher plants are pollinated by an environmental agency. This agency may be a physical factor, as in the wind pollinated trees, or it may be a biological agency, as in the transfer of pollen for many fruits and vegetables by insects. Growth of species populations through reproduction involves the problems of both food and shelter, attack by predator and parasite, disease, co operation and numerous other aspects of general ecology.

THE PRINCIPLE OF COMMUNITY

Even this brief survey of food, shelter and reproduction demonstrates that no organism can live wholly alone and be independent of other organisms. Herbivores must be associated with their food plants, and carnivores and parasites must be associated with their prey. Consequently, since no plant or animal can live in a foodless, biological vacuum, species populations form natural gatherings with other populations. Such assemblages are of various sizes, composition and complexity. They have been called biocoenoses, if the interrelations are especially closely knit, and they are known generally as communities.

Since each species inherits a particular hereditary that allows it to tolerate certain environmental conditions but not others, it follows that the populations of a community can tolerate the normal environment at that place. This environment is complex. It consists of two kinds of influences. There are the physical factors, such as light intensity and quality, temperature, precipitation, evaporation, quality of the medium, substrate, salinity, air or water pressure and many others. There are the biological factors, including food, biotic aspects of shelter, population pressure, predation, parasitism, disease and many more. The community, then, includes both the inhabiting organisms and the physical environment of a particular area.

The Major Community.—When a community is relatively self sustaining and self regulating, it is at the level of survival for its component species populations. Such a community is called a major community. The major community is one of the fundamental concepts in all biology. Normally single celled organisms, such as algae and protozoans, cannot exist apart from their food supply. Similarly, the separate cells of the many-celled organisms are unable to live apart from the tissues of which they are vital units. The tissue is similarly unable to exist apart from other tissues of the organismal whole. Finally, the complete organism (that is, a member of a particular species population) cannot exist without food. Therefore, the populations involved must live together in a major community if they are to exist at all. This is the level at which survival is possible. Consequently, given radiant

energy from the sun the major community is a self-maintaining, self-regulating independent assemblage. There are few exceptions to this principle. A possible exception is found in certain kinds of caves, where the initial food supply is derived largely from external sources. A forest is a major community as is in adjoining grassland, and each is independent of the other for survival. Similarly, a lake is a major community and the vast oceans form a continuous self-sustaining major community.

Within any of these major communities, there are almost innumerable smaller communities that are not self-sustaining, for example, tree holes and decaying logs in forests, cattle droppings in grasslands, the like bottom or profundal community and the coral reef community in the sea.

Major communities have three basic features in common: (1) a fundamental structure, known as stratification, (2) systems of interchange and recombination of foodstuffs, known collectively as community metabolism, and (3) a common system of periodicities.

Stratification.—With respect to stratification the species populations are in a vertical series of horizontal layers termed strata, and usually also in a series of concentric layers, termed zones from the periphery to the centre of the community. Major communities, then, are separable into both horizontal and concentric layers. Since a major community is always in contact with one or more major communities at its boundaries, there is always a marginal zone where the communities intergrade. This intergrading area is known as the ecotone and is familiar to all. The ecotone is a much studied ecotone between the marine and terrestrial communities. Obviously, the ecotone is not a major community since it is not self-sustaining, i.e., it could not exist in its present form without being a part of, and dependent upon, the communities that it connects.

The principle of stratification will be examined again in the discussion of the marine biotic, and forest stratification will be used as an illustration of community structure. A forest almost always has the following strata: (1) subterranean, (2) floor, (3) herbaceous, (4) shrub and small tree, (5) canopy. Each stratum is dependent upon the other four and may be thought of as a community in the general sense but is not a major community. Each stratum has its own microclimate, its particularly adjusted stratal fauna and its peculiar organization. Stratal adjustments are abundant and suggest that the stratum places a positive selection value upon certain kinds of adjustments to maintain position or to procure food and shelter. Generally, stratal adjustments for a particular stratum are similar in widely separated forests over the world and species occupying a given stratum in two such forests may be widely separated taxonomically but may have similar requirements. This is the principle of ecological equivalence.

The subterranean stratum, at the bottom of the forest's vertical gradient, is most similar ecologically to the subaqueous stratum of aquatic gradients. Its matrix of soil particles is relatively continuous and homogeneous. Light is absent, and the soil temperature and soil moisture are relatively stable in contrast to higher forest strata. Here are myriads of bacteria, fungi, soil protozoans, nematode worms, earthworms, almost countless mites, numerous insects, moles and the extensive root systems of trees, shrubs and herbs. Moles are good examples of animals adjusted for life in a certain stratum. They have large horny forefeet for tunnelling, short tails, minute ears and vestigial eyes. These features are fossorial adjustments and are shared more or less by numerous other ecologically equivalent mammals.

The floor is the second stratum. It is less homogeneous and less continuous than the preceding stratum but much more so than all higher strata. Similarly, it is intermediate between higher strata and the subterranean stratum in its physical and biological conditions. In contrast to this latter stratum, the floor is slightly colder in winter, slightly warmer in summer, dimly lit during the day and more easily injured by forest fire and flood. It is an insulating layer retarding erosion and accumulating diverse foodstuffs. Its matrix consists of leaf mould and log mould. Here are included fallen leaves in all stages of decay—providing a

characteristic aspect or habitus to the stratum—rotting stumps and prostrate logs, twigs, nuts, fallen fruit and flowers, faeces of animals and their dead and decomposing bodies. In evergreen forests the leaves tend to fall throughout the year, whereas in tropical jungles and rain forests or in temperate coniferous forests in deciduous forests the leaves tend to be deposited in the autumn season.

In addition to numerous animals that live their entire life cycle in the floor stratum, such as many mites and insects, there are others that spend a part of their life in the floor. For example, ladybird beetles (Coccinellidae) move from the herbaceous stratum of grassland communities, as well as from higher forest strata, to form large overwintering aggregations that hibernate in the leafy floor stratum; other animals nest or shelter there but feed by day or by night in higher strata, still others feed in the floor stratum but have their habitat niches elsewhere.

The three succeeding strata differ markedly from the floor. They are structurally discontinuous since the herbs, shrubs and trees rise separately from the soil. Second, the essential matrix is made up largely of animate material in contrast to the largely inanimate matrix of the floor and soil. These three strata provide large amounts of food for herbivorous insects, such as the leaf-feeding chrysomelid beetles, wood-boring buprestid and cerambycid beetles, sap-sucking aphids and the numerous scale insects (Coccidae) and for herbivorous birds and mammals, as well as for the predators that feed upon this multitude. Many animals shelter in the shrub and tree strata. Deer mice occasionally nest in shrubs and many predators visit shrubs and trees. Tree frogs search for their insect food and the pilot black snake hunts for bird eggs and small mammals.

The leafy crowns of the topmost stratum or canopy interlock to form a forest roof that receives the full force of weather and serves to modify such physical influences as light intensity, light quality, temperature, wind velocity, relative humidity and evaporation rate from the canopy progressively downward to the subterranean stratum. Along the ecotone the canopy often continues downward to within a few feet of the ground and is often secondarily interlocked by vines. In equatorial forests there may be several strata of trees, and true rain forests have three tree strata with correspondingly complex canopies.

All of the five basic forest strata briefly discussed contribute to the well-being of the whole major community. During the seasonal growth period the forest climate is relatively cool, dark and moist, and the air is relatively still in contrast to conditions external to the forest. Furthermore, these physical influences are but a few that operate from canopy to subterranean stratum and from the peripheral ecotonal zone to the centre. Consequently, each stratum differs quantitatively in its microclimate.

Community Metabolism.—Such stratified major communities, whether forest, grassland, lake or sea have a basic system of food interrelations or metabolism. This community metabolism is separable into two interlocking phases: (1) an anabolic phase, in which foods are formed, and (2) a catabolic phase, in which foods are broken down.

Community anabolism is divisible into two basic key industries. These are: (1) the bacterial industry, and (2) the photosynthetic industry. Generally speaking, both of these anabolic phases are dominated by plants.

Dead plants and animals are broken down into organic compounds by many kinds of bacteria, known collectively as heterotrophs. Other myriads of bacteria, known as autotrophs, reduce these organic compounds further into mineralized or inorganic salts. Essentially this is the bacterial key industry. It is fundamental to the life of a community and consequently fundamental to the constituent plants and animals. It is these mineralized salts that are finally absorbed by higher or "green" plants, either through their root systems in the subterranean stratum of terrestrial communities or by algae in the surface layers of aquatic communities.

The photosynthetic key industry is carried out chiefly by green plants and to a lesser degree by the poorly known photoautotrophic bacteria. The plant carbohydrates, manufactured in the photosynthetic process, are combined with mineralized salts, ab-

sorbed by the plants, to form plant proteins. These plant tissues are available for the catabolism of the community. This latter phase is carried out chiefly by animals and fungi. The herbivores feed upon the plants, and in turn, they are available as food to the predators, parasites and hyperparasites in several grades of carnivorous and scavengerism. Consequently all organisms are either directly or indirectly dependent upon the bacterial and the photosynthetic key industries, and these latter processes are entirely dependent upon each other and all of the intermediate stages in the food cycle of the entire community.

Food Web.—In any given community this circulation of foods is an interwoven system of feeding interrelations. The whole system is spoken of as the food web and the separable strands of food and feeder are termed food chains, although it is apparent that a food chain as such, is an arbitrary device for studying a few directly related portions of the food web.

Many examples of food chains are available but almost none are known completely. A simple example may be cited from a prairie community: the sap of grasses is eaten by aphids, the aphids are eaten by larvae and adults of ladybird beetles, the latter are eaten by predaceous ground beetles, such as *Carabus* and *Calosoma*, these ground beetles are in turn devoured by such birds as dickcissels, horned larks and grasshopper sparrows, finally, these birds may be eaten by marsh hawks. In this chain the several links are in relative biotic balance. When the marsh hawk dies, its body will be decomposed by the bacterial industry noted previously, and eventually mineralized salts will be available for absorption by the prairie grasses, completing the food cycle in a single food chain of the prairie food web.

There are several points to be noted concerning food chains. A species may eat different foods (1) in different parts of its geographic range, (2) in different stages of its life history and (3) at different times of the year.

Pyramid of Numbers.—When the food web is examined quantitatively, by counting or estimating the number of animals present per given area or volume of environmental medium, it is found that not only are there many more small animals than large animals, but that the size classes involved form a triangular figure when size is plotted against abundance (fig. 1). Charles Elton in 1927 called this relationship the "pyramid of numbers." Small

Illinois deciduous forest by Orlando Park, W. C. Allen and V. E. Shelford (1939), for an equatorial forest in Panama by E. C. Williams, Jr. (1941), for tree holes by Orlando Park S. I. Auerbach and Glenna Cooley (1950) and for certain Wisconsin lakes by Chancey Juday (1942). The food and feeder relationships in the pyramid were counted mathematically by R. L. Lindeman in 1942 and his formula was extended and modified by Allen, A. E. Emerson, Orlando Park, Thomas Park, and K. P. Schmidt in 1949 as follows.

Trophic Levels.—We may consider the community pyramid of numbers to have four or five trophic levels (levels of feeding interrelations), each level containing a variable number of species and each species population containing a variable number of individuals. In the following formulation of the concept, the symbol Λ represents a trophic level, S is a species population, I is an animal and t is a time component.

$$\left(\begin{array}{c} (I_1, n) \\ (S_1, n) \\ \Lambda_1 \end{array} \right)_t \rightarrow \left(\begin{array}{c} \text{etc} \\ \Lambda_2 \end{array} \right)_t \rightarrow \left(\begin{array}{c} \text{etc} \\ \Lambda_3 \end{array} \right)_t \rightarrow \left(\begin{array}{c} \text{etc} \\ \Lambda_4 \end{array} \right)_t \rightarrow \left(\begin{array}{c} \text{etc} \\ \Lambda_5 \end{array} \right)_t \rightarrow \Lambda$$

Photosynthetic plants Herbivores Carnivores Heterotrophic bacteria and fungi Chemotrophic bacteria

In this system Λ_1 would include photosynthetic plants (either or both higher green plants and the photoautotrophic bacteria), that is, the producers. Λ_2 would include the herbivores, that is, the primary consumers. Λ_3 would include the carnivores, that is, the secondary consumers. Λ_4 would include the saprophagous organisms (heterotrophic bacteria and fungi), that is, the tertiary consumers. Λ_5 would include the chemoautotrophic bacteria, that is, the quaternary consumers. This terminology is one of several devised to clarify major feeding patterns within the whole community. Naturally, all organisms consume, transform, produce and otherwise rearrange and reorganize their protoplasm and their habitats.

Two points need amplification. First, omnivores encompass both Λ_2 and Λ_3 . Second Λ_1 must be factored to allow for several predator grades within this level. That is, S_1 population feeds on Λ_1 , but S_2 usually feeds on S_1 , S_3 feeds usually on S_2 , etc. The result of this series of internal relationships within the level of secondary consumers complicates the third term of the trophic level formula, where P stands for a given grade of predator, as follows:

$$\left(\begin{array}{c} (I_1, n) \\ (S_1, n) \\ P_1 \\ \Lambda_3 \end{array} \right)_t$$

There are exceptions to the pyramid of numbers. These are generally found in animals that have special feeding adjustments which enable them to concentrate on small prey. The whalebone whales strain enormous numbers of minute organisms from the sea, and the paddlefish strains many small crustaceans from the waters of the Mississippi valley.

Biomass.—When a species population is weighed, in part or as a whole, the weight of the population can be examined in relation to other parts of the pyramid or food web. Walter Picketts in 1937 developed this concept in relation to ants and defined biomass as the weight of a species population per unit of area. Obviously, the biomass could be determined for each link of a food chain, or for each stratum of a community or for the whole community.

Productivity.—When pyramids, or numbers of animals, and biomasses, or weights of animals, are discussed, the production potentials for a given area or volume of a given habitat become important. Productivity can be thought of in several ways. There is the annual crop production as well as the standing crop production, this latter meaning the amounts of protoplasm or protoplasmic products present at a given time and place. In these two concepts amounts are involved, as bushels of corn, board feet of lumber or pounds of beef or herring per acre of prairie, forest or sea surface.

A second way of thinking of productivity is in terms of the efficiency of production. For example, E. N. Transeau calculated that the photosynthetic efficiency of field corn (10,000 plants per

FIG. 1.—A MICRO ELTONIAN PYRAMID OF NUMBERS OF THE METAZOAN FAUNA OF THE FOREST FLOOR STRATUM. CARLE WOODS, A GREEN TIGER BEETLE-SUGAR MAPLE-HORNBEAM FOREST NEAR EVANSTON, ILL. FIVE SIZE GROUPS SHOWN.

animals have a higher reproductive potential than larger ones. Since the energy value of food eaten eventually must balance the physiological energy expended in obtaining and assimilating this food, predators generally eat animals in the next lowest size level or so to conserve this energy expenditure. For example, in the prairie food chain cited, the marsh hawk probably could assimilate the aphid protoplasm but the energy expended in eating such minute prey would be greater than the potential energy of the food. Pyramids of numbers have been investigated carefully for only a few communities. The pyramid has been figured for an

acre) was only 1.6% in terms of the total solar energy that was available for one acre. Corn production is usually thought of as high, yet the actual efficiency is low, and the relative efficiencies of animals feeding on this staple food are important to man and his domesticated animals. A third way in which production can be viewed is in direct energetic terms, calculating the rate of production and amount of production in gram calories (g cal) per unit of area per unit of time, using the solar energy as the total amount available. G. L. Clarke discussed this aspect of productivity for a part of the North Atlantic in 1946. His general conclusions are applicable broadly to community metabolism. On Georges bank, off the coast of New England, the energetic input for the marine community in terms of light energy is 3,000,000 g cal per day per square metre of sea surface. The diatoms are important phytoplanktonic organisms in the photosynthetic industry. These abundant minute algae had a net production rate of from 0 g cal to 9,000 g cal per day per square metre of sea surface, that is, the efficiency of diatom production was 0.3%. The zooplankton feeds primarily upon the phytoplankton. The net production rate of these minute, free-floating animals was from 0 g cal to 440 g cal per day per square metre of sea surface, that is, the efficiency of zooplankton production was only 0.015%.

In turn, the fishes feed directly on the zooplankton, or on bottom-dwelling organisms, or are indirectly dependent upon these animals in the case of predaceous fishes at higher predator levels. That is, both zooplankton and fishes are dependent directly or indirectly upon the phytoplankton. These latter organisms are directly dependent upon the light energy and nutrient salts dissolved in the water, as previously discussed. On Georges bank data were obtained on the weight of whole fishes of all species landed annually. Weight of the catch varied from 63,000,000 lb to 289,000,000 lb per year over the 10,000,000 ac of Georges bank. This represents a yield of from 7 to 33 lb of fish per acre per year. Assuming an energy content of 740 g cal per pound for raw fresh fish, the yield of fish landed per acre per year is equivalent to a production rate of 1.6 to 7.7 g cal per day per square metre of sea surface. That is, the efficiency of production was from 0.00005% to 0.00025%.

From this analysis it is clear that production efficiencies decline rapidly from lower to higher trophic levels in the pyramid of numbers of a major community. Naturally, the details will vary as between parts of the same community, and between different communities of the same type and between different types of communities.

Ecological research is essential in productivity problems. At present there is much more solar energy available than is being utilized by plants and animals. Man uses more and more food as his population increases but returns relatively little available energy to the food cycle. When his global population cannot be supported by the available food supply, the problem of overpopulation will affect adversely the conservation of natural resources. Loss of natural resources will in turn adversely affect the food supply.

Periodicity.—Another basic feature in community organization is that of periodicity. The activities of animals, in their search for food, shelter and mates, fall into one of two categories. These are periodic activity and aperiodic activity. Most of the large activities of communities are periodic and are correlated with the regular march of such physical influences as relative length of day and night, daylight intensity, air temperature and distribution of precipitation. In fact, correlation of community activity in the large with the periodic physical environment is essential for survival.

Periodic activities are of three general kinds at the level of the major community. The first of these is seasonal. Involved are the growing season for plants, the mating periods for animals, the several aspects of dormancy including hibernation and aestivation; the correlations in photoperiodicity, or the relation between the leafing, flowering, fruiting of many plants with the relative length of day and night throughout the year, and the problem of migration. Study of periodic, seasonal events is known as

phenology, and when a sequence of phenological changes is followed through the annual cycle and related to environmental factors, the general process is termed seasonal succession, or aspection. The year is often divided into a series of periods that are correlated with seasonal phenomena, such as the peaks of abundance of certain populations that are characteristic of a particular community or type of community. Typical species are frequently known as index species, and their seasonal population peak, or the appearance of some characteristic behaviour or structural change may serve as an index of the time of year as well as the kind of community under examination.

Within this seasonal frame, certain animals exhibit reproductive phenomena that are correlated with tidal or lunar events. Such animals include the palolo worms, e.g., certain marine annelids that swarm and spawn at certain times of certain months. All such phenomena are embraced by the term lunar periodicity.

Finally there are the changes in community activity that are correlated with the regular march of day and night and are termed diel activities. These are divisible into diurnal and nocturnal activities, associated with the day and the night, respectively. Where the crepuscular periods of overlap between day and night are examined particularly, the dawn and dusk periods are termed auroral and vespereal, respectively. Probably the most important diel activity is the diurnal manufacture of carbohydrates by photosynthetic plants. The nocturnal complementary process is the distribution of much of this carbohydrate material to other parts of terrestrial plants. Another diel phenomenon is the vertical migration of many minute animals that inhabit the surface stratum of the sea. These animals include many protozoans and copepod and cladoceran crustaceans. They move to the surface during the night and move downward during the day, apparently as a direct or indirect response to light intensity, as well as being carried passively by diel convection currents.

Communities commonly have a well defined diurnal fauna and a well defined nocturnal fauna, and there are numerous special adjustments that allow animals to compete and co-operate within this diel periodism of the physical influences. The vertical pupil of many snakes, such as rattlesnakes, is not necessarily an indication of their venomous nature but is an adjustment to their nocturnal habits. Some diurnal tree squirrels have the lenses of their eyes slightly yellowish in colour whereas the lenses of the nocturnal American flying squirrels (*Glaucomys*) are perfectly translucent and allow all available light to filter upon the retina. Again, most nocturnal cats have a reflecting layer, or tapetum, back of the retina and a similarly light-reflecting layer is found in the eyes of certain nocturnal moths and beetles. The tapetum is the structure that causes the eyes of such animals to glow in the light of an electric torch at night. The bioluminescent organs of the common fireflies or lightning bugs (lampyrid beetles) are adjustments that enable these nocturnal beetles to mate at night.

Almost all communities are divisible into two periodic faunas, the diurnal and the nocturnal. As a consequence, the number of available habitat niches as well as the population is increased. This in turn increases the number and kinds of possible interrelations and renders the community more biologically complex. By this more complete utilization of the space time lattice, the whole community considered as a unit approaches aperiodicity with respect to day and night in a physically periodic environment.

In the second category of activity, the aperiodic type does not exhibit rhythmic correlation with the 24 hr cycle of day and night. Instead, in aperiodic species populations some individuals are active and some inactive at any given time. Such aperiodic patterns are of two kinds. First, there are those species that inhabit relatively stable environments that are removed from direct periodic diel influences. These include the cave crayfish (*Cambarus pellucidus*) of Mammoth cave, Ky., certain animals that inhabit the relatively constant subterranean stratum of terrestrial communities, or the interior of decaying logs on forest floors, such as the subsoil beetle, *Popillia disparis*, the flour beetle (*Tribolium confusum*) that lives in the relatively stable habitat of stored food products. Second, some of the social animals are aperiodic, such as many kinds of ants and termites. Also, as man's

social organization becomes more complex, his activities as a whole tend to become arrhythmic. Other social species are not aperiodic, as for example many bees and wasps and some ants, but it is difficult to conceive of a wholly social species having its activity rigidly controlled by the periodic environment. Whether animals such as man evolved socially first and became aperiodic as an adjustment to social life, or were aperiodic first and became social later is an unanswered question. At least the aperiodic pattern is correlated with a relatively constant environment, whether this is the complex social medium or a habitat that is removed from direct control of diel factors.

PRINCIPLE OF SUCCESSION

Turning from community organization, another important aspect is the growth and change of communities through time. This process is known as ecological succession and can be separated into two components. The first of these is physiographic succession and has to do with changes induced by physiographic factors. This form of succession was described by H. C. Cowles in 1901 with respect to the series of communities that gradually arose as post-glacial Lake Chicago drained away leaving the smaller Lake Michigan and the Chicago plain in its place.

The effects of physiographic influences were summarized by H. C. Cowles in a classic statement ("The Plant Societies of Chicago and Vicinity", The Geographic Society of Chicago Bulletin No. 2 [The University of Chicago Press, 1901]).

Having related the vegetation largely to topography, we must recognize that topography changes, not in a haphazard manner, but according to well-defined laws. The processes of erosion ultimately cause the wearing down of the hills and the filling up of the hollows. These two processes, denudation and deposition, working in harmony produceplanation, the inequalities are brought down to a base level. The chief agent in all these activities is water, and no fact is better established than the gradual eating back of the rivers into the land and the wearing away of coast lines, the material thus gathered fills up lakes, forms the alluvium of flood plains, or is taken to the sea. Vegetation plays a part in all these processes, the peat deposits adding greatly to the rapidity with which lakes and swamps are filled, while the plant covering of the hills, on the contrary, greatly retards the erosive processes. Thus the hollows are filled more rapidly than the hills are worn away. As a consequence of all these changes, the slopes and soils must change, so, too, the plant societies, which are replaced in turn by others that are adapted to the new conditions.

Successional changes of this kind are widespread and basic. Erosion and deposition of soil by both wind and water profoundly modify the earth's crust within a given climatic period, and such changes alter the structure of terrestrial and fresh water communities to such an extent that established populations of plants and animals are unable to cope with the changed conditions, and their place is taken by other species that can adjust, hence, the communities succeed each other through time.

The second component in ecological succession signifies changes in community structure brought about through biological action, e.g., the numerous changes induced by the plants and animals resident in a given community. These processes and their effects collectively have been termed community development. For example, waste products, faeces, decay of dead organisms, formation of organic soils, filling up of lake and pond bottoms with organic sediments, and other influences gradually change a com-

climax in that, for a given latitude, altitude and climatic period, the physiographic and biotic changes have become relatively stabilized and can be tolerated by resident populations. At high latitudes the substratum of the climax community may be very unstable. Normal community succession may be modified, deflected or arrested within any series. The normal filling up of ponds to form marshes, and of marshes to form pioneer grassland or forest, and these latter to form a climax high grass prairie or a climax beech sugar maple forest in a certain area will occupy a long period of time. This has important practical significance for the formation of man's food supply, his fisheries, duck populations, corn and wheat yields or lumbering activities. Scientific management is clearly indicated rather than hasty action in attempting to alter natural processes. Where a community originates and is maintained by human disturbance it is an artificial community and is termed a disclimax. Where succession and development take place relatively unmolesied by man, or his indirect influences, the sequence is a primary series (priser), where development and succession are controlled by man, or his indirect influences, the sequence is a secondary series (subserie).

Succession and development of a series are also frequently controlled by local conditions primarily, rather than by the prevailing climatic conditions. Local effects are termed edaphic, and edaphic series are common. Two powerful edaphic influences are soil and water. The edaphic aquatic sequences are of two general kinds: the flowing water series, in which the change is from small, swift brooks with high velocity, to the edaphic climax of an old, meandering river that has cut its bed to the base level and meanders through a silted flood plain, and the standing water series, in which the change is from bare bottomed ponds and lakes to marshes or bogs, and finally filling up to form the pioneer stages in a terrestrial series, either grassland or forest, as a rule, depending on the seasonal distribution of rainfall and other climatic factors.

As the community as a whole undergoes this change, there are almost innumerable intracommunity sequences taking place. These are known as microserees and include changes that take place in cattle droppings in the prairie community, in the decaying bodies of animals, the decomposition cycle of fallen logs and stumps, tree holes and the disintegration of fungi in the forest community. All of these microserees follow a regular sequence of biochemical, structural and biotic changes but are without a climax stage as they are incorporated into the major community as it matures.

PRINCIPLE OF CONVERGENCE

Consequently, an important principle emerges at the level of community maturation. This is the principle of convergence. That is, there is a general tendency for edaphic series to run their course, for microserees to wax and wane and for climatic series to mature from pioneer to climax. In the end, often over many centuries, an entire region tends to develop into the regional climatic climax.

Convergence was emphasized by H. C. Cowles in 1901. With his aid, V. E. Shelford applied the principle to the Chicago area in 1913. It was generally treated by F. E. Clements and V. E. Shelford in 1939. The principle is illustrated well in northern Indiana. For example, four series may be mentioned. These are: (1) sand, (2) clay, (3) flood plain and (4) pond. The pond eventually fills, passes through a marshy cattail stage, the ground is captured by a series of terrestrial communities, the sand and clay series accumulate humus and, in the end, all four series meet in the common development of a beech sugar maple forest. This latter is a climatic climax for the particular area. The faunistic and floristic composition of the climax varies with altitude and altitude, but the principle of convergence has many broad implications.

BIOMES

changes may be described, are relatively continuous and to some extent are directional and hence may be predicted. This process of change continues until a stable end product is reached that will endure normally for the existing climatic period. A sequence or series of communities is termed a sere, the early stages are known as pioneer communities and the relatively stable end product is the climax community. This latter community is a climatic

Communities and major communities, whether edaphic or climatic, pioneer or climax, are distributed over the terrestrial parts of the world in a series of broad belts from poles to the equator. In general, although edaphic influences alter the regularity of these

upper waters the diatom population is relatively low in winter, increases rapidly in the spring falls off in summer, increases slightly in autumn and falls again to the winter low. This cycle in seasonal abundance is illustrated in fig 2

Many ecological influences are involved in this population cycle. For example light intensity, water temperature, nitrate and phosphate salts, and winds. Sea water is enriched constantly by inorganic salts that have been formed by bacterial action, and these salts are utilized by phytoplankton in building their protoplasm. In the winter the concentration of these salts is high, but the light is insufficient for maximum photosynthesis and the diatom production is low. In the spring the production is rapid since salts and light are ample, but meanwhile the upper layer of water is warming rapidly and a discontinuity layer forms between the upper warmer and lower colder layers of water. This interspersed layer, because of its electrical properties, prevents upwelling of nitrate and phosphate salts in sufficient amounts to be utilized by the rapidly growing diatom population. Consequently, the production falls rapidly since the diatoms have exhausted the supply of these salts in the upper level, above the discontinuity layer. Summer, then, has a lowered population, although light is ample for photosynthesis. This, incidentally, is an illustration of J. von Liebig's "law of the minimum," which states that growth is limited by the factor that is operating in minimal quantity. As summer draws to a close, the falling temperature of the upper water approaches that of deeper waters, the discontinuity layer disappears and phosphate and nitrate salts are diffused upward by partial pressures, as well as by the mixing of waters that occurs during autumnal gales. Since the light intensity is still sufficient for photosynthesis, and salts are present for metabolism, there is a second, or autumnal, peak of diatoms. This latter does not equal the spring, or vernal, peak since the approaching winter, with its lowered light intensity will prevent an equal diatom population.

The production of vernal and autumnal peaks or pulses of phytoplankton in the temperate zones of the sea are paralleled by similar peaks in large lakes, but not necessarily in smaller bodies of fresh water.

Zooplankton consists of many groups of animals most of which feed upon the phytoplankton. Zooplankton commonly is divided into several categories. There is the temporary plankton, consisting of planulae eggs and larvae of nonplanktonic adults of both fishes and invertebrates. Permanent plankton makes up the rest of the zooplankton, animals that live all their lives as planktonic individuals. Temporary plankton and permanent plankton are called at times meroplankton and holoplankton, respectively. The latter includes protozoans, especially radiolarians and foraminiferans, many worms, jellyfishes and siphonophores, certain molluscs, such as the pteropods and heteropods, and especially crustaceans. These latter are to the sea what the insects are to terrestrial habitats and include chiefly copepods, ostracods and amphipods. The copepod, *Calanus finmarchicus*, is an especially important member of the surface-water community since its numbers provide suitable food for many animals higher in the pyramid of numbers.

Nekton—The nekton consists of animals that can move against currents. These are generally larger animals, including fishes and squids. Most commercially important fishes are nektonic and feed upon the plankton or are predaceous (such as sharks) and feed on other fishes. Marine mammals such as seals, porpoises and whales are nektonic.

Benthos—The last division of marine animals, the benthos, includes those forms that inhabit the sea floor and subaqueous strata of the community. They consist of active benthos, such as many clabs and snails that move over the floor or burrow through the bottom substrate, and the passive benthos, such as numeic colonial coelenterates and sponges that remain attached to the bottom as benthonic adults.

Stratification—Stratification of the sea is both vertical and horizontal. The upper zone or less, are illuminated by daylight that is reduced gradually in intensity and spectral quality with increasing depth. This upper layer is called the photic zone. The plankton inhabit this zone primarily since the phytoplankton must stay in the upper stratum of this zone to carry on photosynthesis, and the zooplankton feed chiefly on these minute plants. Most nekton live here as well, since they too are directly or indirectly dependent upon

the phytoplankton for food.

Below the photic layer is a deep aphotic zone, where light gradually fades out, the water pressure gradually increases and the temperature is relatively constant at a few degrees above the freezing

point. These two zones include the water mass of the sea and are often known collectively as the pelagic division.

The sea floor forms the second or benthic division. It consists of a series of more or less concentric zones that begin at the edge between terrestrial and marine, or fresh water and marine, communities and extend seaward. The sea floor is divisible primarily into two subdivisions, the littoral system and the deep sea system.

The littoral system is again subdivisible into two zones. The first of these is the eulittoral zone, from high tide level on the shore seaward to a depth of about 20 to 60 m. This seaward limit is placed at about the place where attached plants can grow. This photic aphotic limit naturally varies with latitude. Within the eulittoral zone is a relatively well defined intertidal zone that is bounded by high water and low water extremes of tide.

The eulittoral zone as a whole is rich in life, having an abundance of both pelagic and attached plants and animals. Its substrate is also highly variable. There are three chief types—sandy, rocky and muddy—as well as intergrades, such as sandy-muddy.

The second littoral zone is known as the sublittoral. This extends from the seaward limit of attached plants seaward to about the 500 m line. This seaward limit of the sublittoral coincides more or less with the depth of the water at the outer edge of the continental shelf and also more or less with the depth that divides the aphotic and photic zones noted previously.

The deep sea system is similarly divisible into two zones. The first of these is known as the archibenthic zone. It extends from the seaward limit of the sublittoral zone downward to about the 1,000 m line. Its exact lower limit is variable. From about this latter depth to the sea bottom is the second deep sea zone, the abyssal region.

The archibenthic zone is relatively uniform physically. Daylight is absent and the temperatures vary from about 5° to -1° C. Since there are no seasons, the seasonal rhythms so typical of the eulittoral zone are absent. Since there are no attached plants and no phytoplankton, the animal populations consist of parasites, carnivores and scavengers.

The abyssal zone is similar generally in physical conditions to the deep sea zone, save that of increasing water pressure. The abyssal populations are sparse, decreasing in numbers with increasing depth and with increasing distance from the shore. The fauna is thought to be endemic, limited to the area rather than impoverished ecological extensions from higher zones. Scarcity of food appears to be the chief limiting factor. These weird animals are predaceous, feed on detritus or are parasites. Attached plants are absent, save possibly for bacteria; the abyssal forms are entirely dependent on upper levels for food. This is sparse since decomposing animals, falling from the surface layers, are broken down by heterotrophic bacteria in the upper and intermediate strata as a rule. Food input for the abyssal region then, must be derived largely from pelagic animals of intermediate depths that are, in turn, dependent on the surface layers above them. The abyssal animals exhibit numerous structural adjustments to the great pressures of their habitat, and many deep sea and abyssal fishes are provided with bioluminescent organs.

HISTORY

In this brief survey of animal ecology only a small portion of the science can be dealt with. Historically, the subject is old in that some of its material is derived from natural history and some autecology was known to Aristotle. In modern terms, ecology is of recent origin as an organized science. It was established at about the time that another biological science, genetics, was recognized.

In the 18th and early part of the 19th centuries there was considerable tact and fancy in natural history. In 1869 Ernst Haeckel stated that the individual was a product of co operation between the environment and organismal heredity. This relationship he termed "oecology."

Haeckel's "oecology" was more or less forgotten in the activity that resulted from publication of Charles Darwin's theory of natural selection in 1859, which was strange since Darwin's theory was primarily an ecological theory of evolution, stressing the environment as a selection agent over long periods of time. Ecology was placed on a modern basis, more or less, by F. A. Forel in Switzerland in 1891, E. B. Warming in Denmark in 1896 and by the Americans F. A. Birge, H. C. Corbin and F. E. Clements between 1891 and 1905.

Thereafter, research in ecological subjects tended to stress synecological aspects, e. g., population and community analysis. Quantitative and statistical methods increased the scope of the science and more interrelations became apparent between ecology and taxonomy, physiology, biochemistry and geography. Study of microclimate and microhabitat became increasingly important. There was a growing emphasis among ecologists to evaluate their data in terms of evolution and of conservation.

BIOLOGICAL ECOLOGY—The British Ecological Society was founded in 1913 and publishes the *Journal of Ecology* and the *Journal of Animal Ecology*. The Ecological Society of America was founded in 1916 and publishes the *Bulletin* and the research journals *Ecology* and *Ecological Monographs*.

FIG. 2.—THE RELATION OF DIATOM SEASONAL ABUNDANCE TO THE CONCENTRATION OF NITRATES AND PHOSPHATES IN THE UPPER LAYER OF THE SEA AND TO LIGHT INTENSITY ONE OF THE BASES OF THE MARINE FOOD CHAIN (AS ADAPTED WITH PERMISSION AFTER RUSSELL AND YONGE THE SEAS OUR KNOWLEDGE OF LIFE IN THE SEA AND HOW IT IS GAINED PUBLISHED BY FREDERICK WARNE & CO. LTD.)

ECONOMIC ARTICLES The large subject economics is dealt with in this work under many headings. The article **ECONOMICS** is a general survey of the development of economic theory. Further discussions of different branches of the subject will be found in the articles entitled **CAPITAL, EXPORT OR, CAPITAL AND INTEREST, CAPITALISM, COMPETITION IN INDUSTRY, DEMAND, DIMINISHING RETURNS, ECONOMIC MAN, LABOUR, LAND, LAND NATIONALIZATION, LAND TENURE, ECONOMIC AND AGRARIAN ASPECTS, MINIMUM WAGE, PRICE, PRICES, STATISTICS OF, PROFIT, RENT, SUPPLY AND DEMAND, UTILITY, VALUE, WAGES, WEALTH**.

Various schools of economic thought are treated in the articles **ANARCHISM, BOLSHEVISM, COLLECTIVISM, COMMUNISM, CO-OPERATION, CO-PARTNERSHIP, LAISSEZ-FAIRE, MERCANTILE SYSTEM, MUNICIPAL TRADING, PROFIT SHARING, SINGLE TAX, SOCIALISM, SOCIALISM, PRINCIPLES AND OUTLOOK, SYNDICALISM**. A special article is devoted to **FASCISM** in its economic aspect.

For a key to the many articles relating to banking, money, finance and taxation, see **FINANCE, ARTICLES ON**.

The department of fiscal policy is treated under the headings **COMMERCIAL TREATIES, CUSTOMS UNION, FAIR TRADE, FREE TRADE, IMPERIAL PREFERENCE, PROTECTION, RECIPROCITY, TARIFFS**.

For related articles of importance see **COST OF LIVING, HOUSING, LUXURY, PROSTITUTE, RURAL DEPOPULATION, SODIUM, TRADE CYCLE, URBANIZATION, USURY**.

There is a group of articles relating to industrial and commercial combinations under the headings **COMBINATION IN INDUSTRY, COMBINES, COMPETITION IN INDUSTRY, MONOPOLY, PRICE MAINTENANCE, TRUSTS, etc.** For associations of traders see **INTERNATIONAL CHAMBER OF COMMERCE, INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES, TRADE ORGANIZATION**. The organization of labour is treated under **INTERNATIONAL, THE, TRADE UNIONS**.

For the relations of capital and labour see **INDUSTRIAL RELATIONS**.

The problems of poverty are dealt with in the articles **CHARITY, POOR LAW, POVERTY LINE, SLUM, SWEATING SYSTEM, UNEMPLOYMENT, VAGRANCY, WORKHOUSE**.

Under **INSURANCE** will be found reference to various methods of insuring.

As to economic practice and the actual production and distribution of wealth, reference should be made to the economic sections under the heading of each country and, in addition, to the articles **AGENTS IN BUSINESS, AGRICULTURE, A GENERAL SURVEY** (a spe-

cial key will be found under the heading **AGRICULTURAL ARTICLES**), **COMMERCE, EXPORTS, IMPORTS, INDUSTRIAL RELATIONS, RESEARCH, INDUSTRIAL, SALESMANSHIP, SCIENTIFIC MANAGEMENT, STANDARDIZATION, TRADE, WORLD STATISTICS**.

For the discussion of questions of population, in which all economic endeavour may be said to be summarized, see the articles **BIRTH CONTROL, BIRTH RATE, DEATH RATE, MARRIAGE RATE, POPULATION**.

ECONOMIC MAN The term *homo economicus* has often been employed with an ironical significance, by critics of political economy, and has been especially directed against the English economists who founded the Classic school, such as David Ricardo and Nassau Senior. Critics reproach them with having based a science of economics on the conception of an "abstract man," a creature moved solely by exclusively economic motives. The German economists, in particular, have opposed to this conception a rival method, the so called "historical," or "realist," school, which studies *men* (not man) under the sundry aspects evolved in different ages and countries. They maintain that this method alone is fruitful and capable of indefinite renewal, while the conception of the *homo economicus* can lend only to a few general formulas devoid of any practical application. It must, however, be admitted that the science of economics could never have been developed had it not seen men as something more than different individuals and had it not first regarded the characteristics common to all. Long ago Aristotle said, "there is no science except of the general," individuals, objects, facts, being, so to speak, merely accidents, deviations from the true type. The existence of a science of economics implies that men generally, if not invariably, behave in the same fashion when placed in the same circumstances. If they are purchasers, they will always prefer the cheaper of two products of equal quantity, or, if price is equal, that of better quality. If they are workers, they will seek the kind of work which is least laborious and best remunerated. If they are owners of an object, they will not part with it or lend it without return.

The real failing of the early economists was their habit of too wide generalization. The French economists of the late 18th and early 19th centuries, such as the physiocrats and Jean Baptiste Say, declared that political economy is possible only if every distinction of time and nationality is suppressed. The historical school was right in protesting against this conception of a universal and eternal national order, and substituting for it that of economic systems differentiated by time and circumstance. It does not study the "typical man," but the man of the 20th century or of the 1st, the bourgeois or the workman, the man of the west or him of the east, the town dweller and the country dweller, and restricts its concentric circles progressively to approach reality through successive approximations. Nevertheless, these remain generalizations, although increasingly narrow ones. The individual case, the conduct of John or William, so far as it is isolated, "eccentric," as it has been well termed, is of no interest for the economist, unless this individual case, by generalizing itself, becomes the starting point for a new generalization, and inaugurates a new column to a statistical table.

The dispute between the economists of the *homo economicus* school and those of the realist, or historical, school is a revival of the great conflict which divided the mediæval scholastics for several centuries, between the "Universals" and the "Nominalists," the former affirming, with Aristotle, the reality of abstract and general ideas, the latter seeing in them nothing but words, names, categories, corresponding to no reality.

The Nominalists were ultimately victorious, and founded modern science, the product of observation and experimentation. The latter is directed toward the particular, and, indeed, the most minute facts, which were considered negligible by the Universals, are most highly prized by the students of today. It has been said that the domain of discovery begins beyond the fourth decimal point, which is to say that it is only at this point that a universal law can be shaped, unless a sagacious observer sees a new vista open before him. Only when observations, pressed to the last limit of precision, revealed certain discordances in the movement of luminous rays, could Albert Einstein's theory be formulated.

Nevertheless, the rôle of deduction in physical science is far from played out, for while students struggle to relate phenomena to unity, others work unceasingly to discover divergences in that unity. It is the same in the science of economics.

The Abstract Man—The general expression "homo economicus" has, however, a further signification. It is not merely the individual, the "average man", not merely the typical man who unites within himself all the characteristics of the human race. On the contrary, it is man stripped of all characteristics other than the purely economic, that is to say, impelled by no motive other than that of interest. It is here, above all, that this view of the science of economics lends itself to criticism, and seems to merit Carlyle's virulent description of "the dismal science." This criticism is, however, misplaced, for it is obvious that after having reduced man, *ex hypothesi*, to a skeleton, one cannot expect to find in him a heart.

Here, too, we must grant science, even in the case of a social science, the right, even the necessity, of elimination. If a physicist studying mechanics must eliminate all phenomena capable of affecting the motion, such as friction, so much the more may the economist, to clear his way in the tangle of social facts, simplify them by eliminating from his field of vision everything not concerned with the desire of gain.

In the introduction to his "Theory of Political Economy," Stanley Jevons said

"The theory which follows is entirely based on a calculus of pleasure and pain, and the object of Economics is to maximise happiness by purchasing pleasure, as it were, at the lowest cost of pain."

This was the origin of the so-called "hedonist" school. Thus political economy becomes a sort of mechanical science, and can even be expressed in mathematical formulae.

Pure Economy—Attempts have been made to constitute an exact science, known as "pure economy," which was promoted by Cournot and Walras in France, Stanley Jevons in England, Gossen in Germany, and to day has a certain number of adherents. This method appears to us to have a perfect right to a place in instruction, although we cannot think that it has yet enriched knowledge by any very important contributions, except, perhaps, Leon Walras's theory of economic equilibrium.

Pure economy cannot, however, claim to exhaust all political economy. These social mechanics can but give a schematic representation of political economy which is a science as living and as complex as man himself. As in the vision of the Prophet Ezekiel, who saw dry bones live, these skeletons must have been restored to them the flesh and blood removed by elimination. Man is not a creature governed solely by his interests, but also by his feelings, his convictions, his passions. Besides, it must be remarked that his so-called "interests" include very various motives, for there is not only pecuniary interest, the desire of profit, there is also the desire of leisure, that factor which has proved so potent in the struggle for the limitation of the working day, there is the desire for independence, which revolts the working class against the wage-system, there is the desire for security, which creates in every country the immense apparatus of social insurance. Personal interest expands progressively, and becomes family interest, corporate interest, class interest, national interest, and even, reaching its last limit, the interest of humanity.

It is impossible to explain economic evolution if no factors other than side egoism are considered, and the action of altruism is not also regarded. The so-called institutions of social service, solidarity, and mutual assistance—communal conditions inspired by collective interest—grow more numerous every day. Family allowances, for example, supplementary to the wage, occupy a growing place in modern economy. Consumers' co-operatives transform commerce by eliminating all purposes of profit.

If demography is admitted as part of political economy, then the sexual interest must be placed beside and above the personal interest. It is not "economic man" that begets children, for his individual and class interests often conflict with his sexual interest.

Most economists, however, consider that this progressive extension should not pass beyond the limit which should divide

political economy from ethics. Their provinces should remain separate, in the one case interest, in the other duty, in the one utility, in the other justice. We think, however, that it is neither possible nor desirable to respect this dividing-line, which we consider to be arbitrary. No doubt, from the point of view of classification, it may be well to distinguish the two provinces, just as in a library it is proper to separate the books dealing with the two sciences. Yet neither can be ignored in explaining social facts. Study of modern economic questions—social questions, as they are called—shows that one almost always arrives at an *impasse* where political economy fails, and only ethics can afford a solution. The ethics of political economy are justice.

According to pure economy, any price, any wage is just if it has been determined by the interplay of supply and demand under conditions of unrestricted competition. This is the tenet of the hedonist school, and they are right, if the word "just" be taken as meaning "exact," as when one says that a weight "just balances" when the two scales are in exact equilibrium. But what sort of political economy is that which in determining prices and wages eliminates "justice" in its true, ethical sense, and how can it give any solutions to the problems of the present generation, the problem of high prices, or of the remuneration of labour? When the authors of the Treaty of Versailles solemnly proclaimed in art. 427 "labour should not be regarded merely as a commodity or article of commerce" (one of the principles of which the International Labour Office is the embodiment), they meant that labour conditions cannot be treated solely by the principles of pure economy. When the governments of every country endeavour to limit the rise of prices and lower the cost of living, this is because they believe that there is a conception of a just price which stands above that evolved from the blind caprice of the law of supply and demand, and that this higher law ought to prevail.

If we consider the history of labour, we see that it has passed through many stages. Formerly it was impelled by constraint, when slavery was current, later in the stage of wage-labour, this constraint still exists, on account of the necessity imposed on the proletariat of earning its bread, but by degrees, as the working class becomes stronger and better organized, forced labour is replaced by interested labour—already a great progress, not only from the moral point of view, but also from that of the return. Yet another stage may be foreseen—a stage already reached in the liberal professions—where interested labour becomes a social service, a public function, in the noble sense of this term, that is to say, its motive will be duty.

Similarly, as regards consumption, how can the economist set aside every moral consideration regarding the use of wealth, refuse to distinguish between that whose only aim is pleasure, such as the consumption of alcohol, and that which meets the public interest, such as the education of children?

In conclusion, then, it must be said that *homo economicus* has a justification in existing, and may form the object of the abstract science of pure economics, but that the object of political economy is social man—a fact which is, indeed, sufficiently indicated by the very adjective "political." (C. G.)

ECONOMICS The term economics came into general use in the 20th century, replacing the older "political economy" as the name of a somewhat vaguely defined branch of social science. The change of name reflected changes in the discipline itself which had become subdivided into a number of specialties. A separation had been made between a pure science and the treatment of public—and to some extent of private—problems of policy, more or less explicitly applications, also, another separation was made between empirical fact—historical or statistical—and theory. The word economy comes from two Greek roots referring to the management of a household or estate. But in the past two centuries or so, the meaning has become generalized to cover all use of means in such a way as to husband them, to make them go as far as possible. Political economy itself is a modern term. It was introduced about the beginning of the 17th century (in French—corresponding to the German *Kameralwissenschaft*) to describe the study of the problems of the princely states which at the close of the middle ages in Europe replaced

the feudal ecclesiastical political order. It referred to the economic affairs of the state or principality—the raising and use of revenue and increase of resources—treating the state as the estate of the ruler. But this study never was generally known by this name. After the nationalistic epoch gave way to individualism or liberalism at the time of the enlightenment in the late 18th century political economy was adopted as the name of a science based on the new moral and political world view, and the older "statistic" literature came to be designated as mercantilism.

Epochs in the Development of Economic Thought—The sketch above suggests four main periods or epochs in the evolution of modern economics, corresponding to those usually recognized in European history. They are the Greek (or classical in the meaning of general history, but the Roman contribution was minor), the mediaeval, the early modern (16th to late 18th century) and the modern, roughly the 19th century. Each corresponds to a distinctive political order and to distinctive conceptions of man and society, and it is an important fact that books were written by and for different social classes in the different periods. The Greek literature was written by aristocratic philosophers and publicists, and related to the problems of the city state, nominally democratic but based on slave labour and with further exclusion of the merchant and financier from civic life. Such writers as Plato and Aristotle commented on many of the obvious facts and principles, such as the importance of division of labour and the use of money. But their interest centred in such moralistic and metaphysical notions as the condemnation of lending at interest as unnatural. Modern knowledge of the economic and industrial life of ancient Greece is derived mainly from other sources, incidental references in literature and archaeological remains. Many of the ideas were in fact survivals of primitive attitudes—they are found also in the older parts of the Bible and survive as a strong influence even today.

Mediaeval economic thought is still more moralistic, and alien to the modern outlook. The literature was produced chiefly by and for monks, at a time when the monastic life was accepted as the ideal, when worldly interests were denounced in favour of salvation in a future world as the one serious concern of man. The dominant social organization was the church, and recorded thought was more of the nature of preaching or theology and metaphysics than of science, as words are now used. For this world, the accepted ideal was a static or customary society and civilization, every man working out his lot in the situation to which he had been called. Trade was frowned upon beyond limited routine exchange at "fair"—meaning customary—prices, corresponding with a customary standard of living for each social class and interest taking was condemned outright. In the later middle ages, however, the canon law and the church courts played a large role in everyday affairs, and the monasteries themselves were the spearhead in great advances in both industry and trade, as well as agriculture. Numerous evasions of the prohibition against interest taking, achieving the same result through other contractual arrangements, came into use and were recognized as legitimate. Men's interests were shifting to the concerns of earthly life, cultural, aesthetic and scientific, as well as material, i.e., political and economic. The evolution of economics must be seen as integral with that of economic life and of European civilization as a whole.

The third period is best designated as that of economic nationalism but the economic thought is usually called mercantilism (See **MERCANTILE SYSTEM**). It dealt with the economic policies of the national monarchic states which displaced the feudal order at the close of the middle ages, and in general dominated the church, whether or not they established national churches, following the Reformation. Vast changes came over social life and men's conceptions and interests. A great cultural renaissance spread from Italy to Northern Europe, modern science, based on observation and measurement, displaced speculative thinking and technological advances were made in all fields. Paper and printing, and especially modern Arabic notation, the foundation

of both science and business, were even more important than gunpowder and the compass and greatly improved methods in mining and metallurgy. The distinctive writings on economic matters were produced by political pamphleteers. It was the age of the commercial revolution, the monarchic states saw wealth obtained through foreign trade as the basis of political power, and money as the embodiment of wealth (*pecunia nervus belli*). Europe was flooded with silver and gold, especially from the new world, chiefly by way of Spain, and the northern countries which had no mines, at home or in colonies, centred attention on sharing in the treasure through a favourable balance of trade and an excess of exports over imports. A quasi alliance was formed between the governments and the wealthy merchant and financier class, against the ecclesiastical power and the higher nobility. Meanwhile, social, moral and intellectual as well as economic forces had tended, especially in the towns, to the emancipation of labour from slavery and serfdom. But men were not ready for the ideal of individual freedom, an authoritarian state took the place of the church and of the town oligarchies that grew out of the guilds as the local regulative authority, and its aggrandizement became the accepted end of policy, with control over economic life as the means.

Mercantilism flourished from the 16th century down to the 18th, and was exemplified in innumerable writings and in the restrictive and regulative policies of such statesmen and rulers as Jean Baptiste Colbert, Lord Burghley, Oliver Cromwell and Frederick the Great. Besides attempting to secure a favourable balance of trade (an excess of exports, bringing in money or bullion), other aims were low interest rates, low wages, encouragement of population growth and colonies. It has been interpreted as nation building, and as an advance toward free trade, which was promoted within the national domain, in contrast with the application of similar policies by smaller units in the mediaeval towns. Whether the measures advocated met the immediate needs of the times is still a disputed question. In economic terms, the fallacies have long since been exposed, but the general attitude survives today, as the reader will observe, in protectionism. Contrary to the admitted advantages of international specialization this is favoured and practised not only by the national states but by smaller units, such as the U.S. states and municipalities.

Transition to Modern Political Economy or Economics—

Modern economics is an aspect of modern thought and of the individualistic or liberal outlook on life, of which capitalism, or the competitive system or free business enterprise, is the expression on the economic side, as democracy is on the political. Our fourth epoch takes its rise in a second great cultural revolution in western Europe, in which the period of the Renaissance moved into the enlightenment, or age of reason. In this development, leadership shifted, in the early modern period, from Mediterranean Europe to the northern countries, and especially to England, with the British colonies in North America playing an important role. England escaped the wars of religion which devastated western continental Europe for more than a century after the Reformation, and here especially religious toleration eased the tension between church and state. England was predominant in the great scientific movement of the 17th century, and the great Civil War and the Revolution of 1688 established representative government at the same time that the treaties ending the Thirty Years' War fastened political absolutism on the major continental states. In England, science was inspired with a "practical" philosophy, formulated by Francis Bacon, a contemporary of Galileo Galilei, the heir of Nicolaus Copernicus. This movement led naturally to the technological revolution of the later 18th and early 19th century, which involved the triumph of free enterprise, and modern economics is essentially the theory of free enterprise. It is interesting to observe that the great mercantilist writers of the later 17th century in England (contemporaries of John Locke in political philosophy) were in substance free traders, as Sir William James Ashley has pointed out in detail. Thomas Mun's famous booklet, *England's Treasure by Foreign Trade* (published posthumously in 1664 but in circula-

tion much earlier) sophistically used the balance of trade argument in favour of freedom to export specie. Other writers, such as Charles d'Avenant, Nicholas Baibon, Sir Josiah Child and especially Sir Dudley North, worked out the theoretical argument for freedom in foreign trade about as explicitly and clearly as did Adam Smith himself, nearly a century later. North argued that the wealth of a nation is that of its citizens and that the businessmen, traders and producers are the best judges of when trade involves a net gain. It remained for someone to apply the same reasoning to internal policy against the surviving guild restrictions or national control of apprenticeship, of wages and interest, grants of monopolies and the like.

All through the later mercantilist period, economic relations were gradually becoming more free, controls falling into disuse, particularly in England. The process, like the earlier disappearance of serfdom, is one of social development, to be explained by the sociologist and culture historian, the formulation of a general theory lagged behind the factual change, at least until the latter was far along. In notable respects the statement of free trade doctrine came earlier in France, where the movement itself was much slower. It was here, of course, that the phrase *laissez faire* (earlier associated with *laissez passer*) originated, in the first half of the 18th century. The kingdom of France was still subdivided into many districts with customs frontiers, until after the Great Revolution. About the same time appeared one of the most notable of the books anticipating the liberal point of view, the somewhat mysterious *Essai sur la nature du commerce en général*, by Richard Cantillon. It is apparently a translation, perhaps by the author himself, of an English manuscript which has disappeared. Cantillon showed a fairly clear insight into the mechanism by which a free market will direct resources into the production of the goods most in demand. Similar insights were conspicuous in the nearly contemporary essays of David Hume, though he wrote no systematic treatise. Early in the second half of the century much attention was attracted by the writings of a French school, who called themselves *les économistes* but are now referred to as the Physiocrats. The word is practically equivalent to law (or rule) of nature. The leader was the court physician François Quesnay. Like many of the mercantilists, these writers used rather absurd if ingenious arguments, and it has been pointed out that the position was connected with the self-interest of certain groups that had achieved wealth and power in the disturbed conditions in France after the death of Louis XIV, especially in consequence of the ambitious schemes of John Law and the famous "Mississippi Bubble." (A similar wave of speculative fury in England at the same time is known as the "South Sea Bubble," from the name of the most spectacular of many visionary or fraudulent companies that were organized.) But the Physiocrats are to be credited with an attempt to see and analyze a national economy as a whole. Their most characteristic doctrine was the view that only agriculture yields a "surplus" beyond what is required for the support of the workers, hence land rent alone is available for the support of the state and higher culture or the increase of wealth, and is the only proper subject for taxation. These ideas survived in part in the work of Adam Smith and the British classical economists. The pre-Revolutionary statesman, Anne Robert Jacques Turgot, renowned for his courageous but abortive economic and fiscal reforms, was to some extent a disciple, his work, *Reflexions sur la formation et la distribution des richesses* (1766), is an exceedingly able treatise.

The Classical Political Economy—In 1776 Adam Smith published *An Inquiry into the Nature and Causes of the Wealth of Nations*, a work in which wisdom, learning and the power of analysis are joined to an extraordinary degree. As already noted, Smith shared many of the popular prejudices that were evident in the writings of the Physiocrats. He held that "in agriculture nature works with man,"—as though this were not true of all other pursuits—and that only labour is productive, and indeed only that labour is really productive which at least reproduces the capital which supports it. Also that the interests of businessmen, as a class, are more often opposed to the interests of the com-

munity than are those of landowners. Nevertheless, Smith gave the world a new view of the advantages of trade as a mechanism for working out the division of labour, and a new philosophy of commerce. But he saw in commerce, as well as internal trade, a means to welfare, not merely to the aggrandizement of the state. His book was in one leading aspect, a formidable tract directed against mercantilism. Money, from the communal point of view, he held to be merely an instrument, a wheel of trade. The real source of a country's wealth, he said is its annual labour, and its wealth or well being could be increased only by making its labour more effective, particularly by extending specialization and accumulating product in the form of capital. ("For 'labour' we should now say 'productive resources'") "The division of labour is limited by the extent of the market" is one of his most famous sayings.

These were Adam Smith's fundamental principles. He elaborated them with great skill, in relation to concrete problems, showing unusual powers of fresh observation in his selection and use of illustrative material, and passing large sections of economic history and the whole range of the contemporary commercial and fiscal problems of Britain under survey. Although the book is the most influential brief ever formulated for unimpeded trade, neither hampered nor coddled by governments, its greatest importance lies not in that circumstance, but in the general picture, at once simple and comprehensive, which it gives of the economic life of a nation. It shows how the apparent chaos of competition, the welter of buying and selling, are resolved or transmuted into an orderly system of economic co-operation by means of which, under individual freedom in contrast with central direction, the community's wants are supplied and its wealth increased. This general picture has been in the minds of economists ever since, whatever their opinions with respect to the efficiency or morality of the competitive system, and its general outline is admitted even by collectivists to be valid for their systems. Despite some sweeping phrases which invite another interpretation, Smith was no doctrinaire advocate of a hands off policy by governments in respect of economic matters. His treatment must be understood against the background of conditions of his day, in which so much was a hold over from the period of mercantilism and even the middle ages. He was opposed to monopoly, exclusive combinations, and special privileges of all kinds, quite as much as he was to the type of legislation which aims at fostering a country's prosperity by restricting its trade. He is often styled the "apostle of self interest," but he took no pains to conceal his dislike for some of the forms in which self interest manifests itself in trade and industry, and had no aversion to legal measures wherever they actually promised to be beneficial. What his attitude would have been under the later conditions of the 19th and 20th centuries towards the factory acts, social insurance and particular measures intended to foster equality of opportunity, we cannot tell. But there is nothing in the aims of these newer types of legislation which runs counter to his principal contentions or is inconsistent with his general economic philosophy.

Adam Smith's work had a profound influence, not in Great Britain alone, but in almost every part of the western world. It was partly responsible for some radical changes in the commercial policies of governments, though its influence cannot be measured, because the current of the times was moving in the direction of his contentions. Its effect upon scientific thought and upon the character and quality of public discussions of economic questions cannot be questioned. Men like Jean Baptiste Say in France and Karl Heinrich Rau in Germany based their work very largely on Smith's and helped to diffuse his influence. Say, however, was more than a mere popularizer. He had some clear-cut views of his own and developed Smith's work in directions other than those it took in the hands of Smith's British successors. In the United States, Say's work came to be about as widely read as Smith's.

The particular trend which the development of economics took in Great Britain after Smith was largely determined by the character of the economic problems which confronted the nation, partly by reason of rapid changes in its own industrial structure

(the industrial revolution) and partly in consequence of the French Revolution and Napoleonic Wars. Population increased rapidly and in particular there was a "mushroom" growth of new industrial towns, foreign trade expanded, especially the export of industrial products and import of agricultural, reversing the previous situation, yet agricultural cultivation was extended, with commercialization of farming and a vast improvement of methods both of tillage and of stock breeding. The changes were accentuated by interference with trade through the wars and governmental effort to maintain self-sufficiency in food (or to benefit the landed interest, which controlled the government), land rents rose with the increase in agricultural prices relative to industrial, the currency was depreciated (a practically universal accompaniment of any major war), rates of interest and of profits were disturbed and, after the peace, both industry and agriculture experienced depression conditions. Some of these conspicuous and important phenomena engaged the attention of parliamentary committees, all of them attracted the interest of thoughtful men who, with Adam Smith's picture of the mechanism of organized economic life in their minds, thought of them as inter-related, and attempted to explain them in some consistent and comparatively simple way. Out of the discussions of the period, in pamphlets and controversial tracts, there emerged a formal system of political economy. It owed much to Smith, but it stressed matters to which he had given little or no attention, and amended his views at a number of important points. This newer political economy was concerned more largely with abstract general relations, but it dealt with real problems and dealt with them in what was intended to be a practical way. There is an appearance of paradox, but only an appearance, in the fact that the type of economics which grew out of attempts to deal intelligently with the problems of a period of economic storm and stress was one which gave particular attention to normal tendencies and to the conditions of economic equilibrium rather than to the immediate causes of economic maladjustments. A parallel may be found in the way in which the study of pathology has contributed to men's knowledge of normal physiology.

For convenience, the period of which we are now speaking may be taken as definitely beginning with the publication of David Ricardo's *Principles of Political Economy and Taxation* in 1817, and as culminating with the publication of John Stuart Mill's *Principles of Political Economy* in 1848. One who comprises the economic tracts and the systematic treatises of that period with the *Wealth of Nations* will be impressed with the increased importance given to a group of problems which have continued to be principal concerns of economics, problems now commonly grouped under the head of theory of value and distribution. These problems of price mechanics unfortunately tend to get separated from the real issues, of the way in which the price system organizes production and distributes the result. The theory of value, of course, attempts to explain why goods exchange at particular ratios, why some are relatively expensive and others cheap. (Absolute money prices are of course a matter of the value, or purchasing power of money, a distinct problem.) The modern theory of distribution is really a part of value theory, dealing with the prices of productive services, with a view to explaining the sharing of the national income or social dividend, or why some are poor and others rich. But the classical economists (from Smith to J. S. Mill) did not look at the problem in this way; they held a more metaphysical theory of the division of the total product into the three traditional shares, wages of labour, profits of capital and rent of land. This theory will be considered presently. Later on, the conception of a fourth share, the profits of enterprise, or of the successful direction of production, was taken over from the French economists (Say and his followers), the earnings of capital, separated from the entrepreneurial functions of management and responsible risk-taking, came to be called interest (whether actually paid out for borrowed money or imputed to that of the owner, an individual or a group). This has been more true in the United States than in Britain, where economists still rather typically speak of the profits of capital, in the language of business and of everyday life. And the

treatment of enterprise or risk-taking (better called uncertainty bearing since there can be no measurement of the risk as in gambling or insurance) raises problems on which there is no general agreement among economists.

The three fold (or four fold) classification of factors is clearly in part arbitrary. Some economists use a two fold classification, treating land as a particular form of capital, others point out that a logical classification would recognize many different kinds of capital, of labour, and of natural resources, with some kinds under one head economically less similar to others in the same class than to some in other classes. And it must also be recognized that in the long run, all productive agents largely represent a cost of production, an investment of resources, in the past (with wide variation in the relation between such cost and present value because of uncertainty), and that this investment is more or less subject to recovery and reinvestment in other types of productive agent. Yet the three forms of income are very real to ordinary thinking, which does not distinguish, for example, between the four or five elements obviously present in most personal earnings. One part is based on natural capacity, one on the "pain" or irksomeness of the work, one on the investment in training, and there is the factor of risk or imperfect foresight, which so profoundly affects the return on any investment for return in a fairly remote future, and finally, noneconomic motives affect in special ways the investment in human capacity. A somewhat similar analysis could be made of the payments for the use of what are commonly classed as either natural resources or capital goods. (See CAPITAL AND INTEREST.)

The classical theory of value stressed chiefly the tendency for the prices of goods produced and sold under competitive conditions to be proportionate to the respective costs of producing them. However, costs meant not the money outlays of the producers (entrepreneurs) but the "real" costs, human sacrifice or pain. For Ricardo in particular this in turn meant quantity of labour, that labour alone is really productive, other factors only assisting, was basic to the labour theory of value, which was taken over and exploited for propaganda purposes by the various schools of socialists and economic radicals. Later, the notion that the abstinence involved in saving and accumulation of capital is also a pain cost was introduced by Nassau William Senior (*An Outline of the Science of Political Economy*, [1836]). The socialists of course scornfully rejected this innovation. The classical economists did not see, at least not at all clearly, that what is economized is the use of resources, both human and nonhuman, and that the ultimate meaning of the cost of any product is the nonuse of resources for some other end. This fact is now known as the alternative cost principle. But the alternative end sacrificed is not always and entirely a quantity of another marketable product, it may be the leisure use of time and labour, or some direct (non-market) use of any other resource. Interpreted in this way, the notion of pain cost has some validity. It should be noted that, as all modern economists have recognized, the cost explanation of value applies only in a long-run view, over time sufficient to adjust production to demand. The classical economists freely recognized that over short periods, price depends on demand and supply, i.e., the demand for the existing supply already produced, or for which commitments have been made.

A similar division between short and long run views was inevitable in connection with the theory of distribution. Neither theory has stood up well under later criticism, though many important facts and principles were recognized. In a general way, the short run theory held that labour gets as wages its means of subsistence, and the capitalist the excess of the product (of labour or labour-plus capital) on marginal land—or at the intensive margin on better land, in any case where no rent was deducted—after payment of a subsistence wage. Land (of a quality above that barely worth using) received as rent the excess (surplus) product above that of the same amount of labour and capital on no rent land. The foundation of the position is the subsistence theory of wages, but it is hard to make out whether this limitation to a minimum was due to the power of the employer over the worker (Adam Smith sometimes comes near to stating the

exploitation theory of the later socialists) or to a tendency of the working population to multiply up to the means of subsistence. The latter view (more conspicuous in Smith's treatment) would clearly operate only in the long run. And somehow, another theory must be fitted into the picture—that of the famous wages-fund. In its simplest version, this meant that the capital (the annual product or some ill defined part of it) was supposed to be advanced to labourers each year, making the average wage simply the total capital divided by the total working population. Ricardo and later members of the school recognized that the period of production or turnover is longer than a year in industries employing fixed capital, but they failed to see that capital is never produced by labour alone but rather reproduces itself (unless it is disinvested), so that no determinate period or cycle in production can be found.

In the long run theory of distribution, the notion of cost played a part—though not as large a one as it logically should have in view of the fact that all productive agents, human or other, are in a general sense products. In the long run interpretation the idea that the standard of living determines wages is in effect a cost of production theory of the price of labour. This doctrine rested upon the theory of population associated with the name of Thomas Robert Malthus, though it was clearly stated in general terms by Adam Smith and by still earlier writers. In the later form, the notion of subsistence, as a physiological minimum, was replaced by, or interpreted to mean, a standard of living, a scale or level which labourers think of as necessary in order to undertake family life. If wages fall below that level, it was thought, the rate of growth of the working population will be negative (births fewer than deaths), and the decline in the labour supply will raise wages. If wages are above this level, population will increase and wages will fall—unless a higher standard of living becomes effective as a control of marriage. Somewhat similar reasoning was applied to profit, the rate of return on capital. The supply tends to increase as long as the return is above what savers generally consider sufficient to compensate for the abstinence required to save, and will decrease when it is below such a level, hence the rate of profit tends toward this level as a position of equilibrium.

The rent of land, however, was held not to be affected by the principle of cost. Land was thought to be permanently fixed in supply, it was deemed by Ricardo as "the original and indestructible powers of the soil." Hence, a rise in rent will not tend to counteract itself by bringing forth an additional supply—or reciprocally for a decline. Correspondingly, as already noted, rent was not supposed to be a part of or to influence the price of its produce, which in this view is determined by their cost (wages plus profit) on land barely worth using and yielding no rent—or by the cost at the intensive margin. Changes in rent were thus the effect, not the cause, of changes in product prices. This doctrine rested on a sharp separation between land and capital (capital goods) which later economists have tended to view as unrealistic. It also rested on an assumption that land is used only to produce a single distinctive product, hence is not, like labour and capital, transferred from one use to another in response to changes in relative prices. This view has also given place to recognition that raw produce is less a product than a stage in the production of all final products. But there is an important element of truth in the older views. In the classical system of distribution as a whole a very important place was ascribed to the "law of diminishing returns," in a particular long-run or historical interpretation. As the theory ran, the growth of population, itself dependent on growth of capital, requires resort to poorer land and also to more intensive cultivation of land already in use. In either case, the increase of product would not be proportionate to the increased amount of labour (and capital). Manufactures, in contrast, were thought to be subject to increasing returns, because of larger opportunities for the economies of the division of labour and for invention and the application of the fruits of scientific progress to industry. Agriculture also benefits by technical progress, but here the possibility of improvement was thought to be smaller and to be more than counter-

balanced by the increasingly disadvantageous proportioning of labour and capital to land. Since labourers must always get the same real wages—the means of subsistence—the profits of capital must decline, until the growth of population and wealth would come to an end in a stationary economy. Taken as a prophecy, this doctrine has so far been disproved by the course of events. The possibilities of improvement in agricultural technique were underestimated, new lands of good quality have been brought under cultivation and their produce brought to market by cheap transportation, and the Malthusian "law" has been partly falsified by declining birth rates going with the general progress of civilization—the rise in the effective standard of living already referred to.

Any general system of value theory must have something to say about the measure of value, hence the value of money or the general price level, in contrast with relative prices. This problem was of especial concern to Adam Smith, because of the price revolution which had swept over Europe after the discovery of America, and of its startling effects. And later this interest was nourished by the monetary and price changes of the period of the great wars of the French Revolution and of Napoleon. On this point, the classical school held to the doctrine later known as the quantity theory of money—other things being equal, the value of money (and reciprocally the price level) depends on its quantity in relation to the volume of production and trade. Allowance would also be made for the use of money substitutes, such as bank credit, already familiar in Europe. As a long run view, this was supplemented by the notion that the quantity of money is determined by the costs of mining the precious metals. Among different countries, especially those with and those without mines, prices would tend to be equalized by a flow of money or bullion from countries in which it would buy less to those in which it would buy more. This part of classical value theory has in general stood up better than the views on value and distribution. It would be an error to think of these earlier economists as altogether preoccupied with abstract theories, or not to recognize that their interest in these was born of an interest in practical problems. And in general, they were not such uncompromising opponents of any sort of interference by government in industry as some later critics and pretended expounders of their views have made them out to be.

The Critical Schools.—Before reviewing the later progress of economics, especially the revolutionary developments of the later 19th century, it will be helpful to look at the principal types of criticism which have been directed against the older political economy, and in part are still maintained against the later developments, and at the conceptions which have been proposed as replacement. In the first place, romanticists, like Adam Müller in Germany and John Ruskin in England, intensely disliked the new individualistic economic mechanism into the workings of which the economists were trying to probe. And consequently, they particularly disliked the defense of this mechanism, of economic *laissez faire*, which the economists in general did defend, by statement or implication. They preferred an ordered society, with economic subordinated to moral or religious or aesthetic values, such as they typically thought had been more or less fully embodied in the social structure of the middle ages. Work, they inclined to insist, is not merely a means to an end, particularly what are called economic ends, good work is worth doing for its own sake and for its effect upon character. They did not impugn the fitness of economics as an instrument of attack upon its special problems so much as they belittled these problems.

Another group of writers, for whom there is no better descriptive name than "the critical school," come much closer to meeting the orthodox economists upon their own ground. One of the earliest, and much the most influential, of them was Simonde de Sismondi (*Nouveaux principes d'économie politique* [revised ed. 1827] and other works). Other able writers, often without any conscious discipleship, have taken a similar position. These critics urge that more attention be given to the defects of the competitive economic mechanism, even viewed merely as a means of providing

for material needs. They contend that the economists contemplating the long run or normal tendencies and the theoretical beauties of the automatic processes by which the pursuit of individual economic interests becomes or may become a vast scheme of economic co-operation forget how often the mechanism breaks down and normal economic life is interrupted by crisis and depression. How unemployment chronic as well as epidemic, is a disease of this economic order, how unequally the aggregate product is distributed among individuals or families, and how many of the things men do for their own economic advantage are in fact inimical to the interests of the community. As later critics have put it, businessmen are interested primarily in making money, which does not always mean making more goods. The picture of the economic harmonies (the title of a mid-nineteenth century French apologetic work) requires, it is urged, rationalizing of the facts to an unwarranted degree. These criticisms also undoubtedly go too far. They unduly play down the role of the abstract principles stressed by the older economists, in the general course of the economic activities of the community. And no economist of the first rank has ever been a devotee of the pure tutism of the market. But the critical school has had a wholesome influence on the progress of economic science. It should be observed that this school occupies a position between that of the orthodox school and that of the socialists who denounce the works of the latter as mere apologetics, a product of the existing economic order and prompted by the interests of those who benefit by its iniquities.

Another line of attack was adopted by the historical school—or more accurately, "schools," since the term covers several different groups. This position has been represented in all countries, but it has been most influential in Germany. The most important of its early exponents were Friedrich List (*Das Nationale System der politischen Ökonomie* [1841]) and Wilhelm Roscher (*Grundlagen der Nationalökonomie* [1854] and other works). The term of a nation's economic life, said these critics, is a historical category, peculiar to a given nation at a given time, a product of its past and therefore only to be understood through a study of that past. The wisdom of particular economic policies is relative to conditions of a place and time, and the supposedly universal laws of abstract economics need to be supplemented by or even subordinated to study of concrete facts of the national situation. If they had gone no further, the historicists would have found many to agree with them. But they tended to make of the historical method something arbitrary and doctrinaire. (Karl Kries, whose work, *Die politische Ökonomie vom Standpunkte der geschichtlichen Methode*, appeared in 1893, is a notable exception.) Not content with looking to history for the causes of these concrete differences of economic structure in which they were interested, they proposed to derive from history itself universal and binding laws, akin to those of the physical sciences. They were fond of schemes of stages of economic development through which they thought every nation must pass. In these speculations they were really elaborating suggestions found not in historical research, but in the Greek speculative historians. They regarded the forms taken by economic life, past and present, as inevitable products of historical forces, and at the same time, unconscious of the inconsistency, they advocated a rather heavy handed control of economic activities by the state.

The British and French economists had looked upon the organization of economic life as being shaped and determined by the interplay of the interests and rational activities of individual men, and had viewed the state as an instrument of individual purposes—well being as judged, in the main, by each person for himself. The spokesmen of the historical school, in contrast, were strongly influenced by the philosopher Georg Wilhelm Friedrich Hegel, who ascribed a prior and independent value to the state, with individuals somewhat in the role of means, on the analogy of cells or organs in the human body, the view is related to that of the mercantilists, though more sophisticated. Although they pushed their views to extremes, they gave a needed emphasis to what has come to be called the institutional view of economic activities, as contrasted with the individualistic or contractual aspect. But

both the older historicists and the later institutionalists (largely a U.S. movement of the early twentieth century) slurred over the contrast between two kinds or meanings of institution, i.e., patterns of action moving in predestined grooves under the influence of relatively unconscious social forces, versus those embodying deliberate organization and control, such as the political organs of the state. The state, in turn, was conceived by the older schools in what would now be called totalitarian terms, while the institutionalists, like the socialists (in contrast with the communists) thought of it as democratic. Historical economists have also been more ready to think of change, as contrasted with finality, in the pattern of economic organization, and they gave a useful impulse to the study of economic history, which is valuable both in itself and as a complement to economic theory. Under the influence of historical study the old dogmatism of the historical economists gradually gave way to a realization of the variety and complexity of the fabric of economic history, and the newer schools of historical economics, under the leadership of such scholars as Gustav von Schmoller in Germany and Ashley and George Unwin in Great Britain (to name only men no longer living) are, as they should be, devoted to historical research. The movement also broadened out, particularly in Germany, under such leaders as Max Weber and Werner Sombart, into what is often called sociological economics, a position also well represented in France (François Simiand, Maurice Halbwachs, C. Bouglé).

The Progress of Economic Theory—Economic theory is the name now commonly given to the more general and abstract parts of economics, the principles. These parts are no less practical than concrete descriptive or applied economics, but are less directly related to immediate problems. The mechanics of price relations or of markets afford a general explanation of the organization of production and distribution in so far as this is actually worked out and controlled through competitive buying and selling—which would largely be true even in a planned or socialistic economy that stopped short of complete military regimentation. This branch of the study bears somewhat the same relation to economic politics that pure physics bears to the engineering sciences. Hence the problems of value and distribution have continued to hold their place among the central concerns of economists. However, there has been a notable—one might say a revolutionary—change in the general character of the analysis. The older classical economists, as we have seen, centred their attention on the long run relations between value and costs and were generally content to dispose of short run variations of price by merely invoking the formula of demand and supply. This was used without careful analysis of the short-run situation, particularly of the role of demand. Work directed toward filling in this gap had important effects in changing the whole conceptual picture. Similar steps introducing the new analysis were taken independently and almost simultaneously, in the early 1870s, by William Stanley Jevons in England, Karl Menger in Austria, and Marie Esprit Léon Walras in France and Switzerland. (It presently became known that they had been in part anticipated by earlier writers who were ignored and forgotten.)

Adam Smith, in a famous passage, had contrasted value in use with value in exchange, noting that the former is high for water and low for diamonds, and conversely for the latter. The new discovery was that there is nonetheless a definite relation between value in use (or utility) and exchange value, hence price. The value in use is not properly measured by the difference between having the normal supply of a good and having none at all, but by the difference it makes to have a little more or a little less, that is, things are actually valued by increments in consumption. Water, for example, has a wide variety of uses, all progressively satiable, and its exchange value at a particular time and place depends on its marginal use, the use and the degree of importance in that use, which would have to be forgone if the supply were just a little smaller. From the standpoint of action since a buyer has choice of how much he will take, all units are alike and the use value as well as the exchange value of any total supply is the product of the value of the unit (increment) in the least important-use by the number of units. Thus where water

is scarce its value—both use and exchange value—is exceedingly high, because the marginal use meets an intense desire or need, and if diamonds were abundant enough their value would be small. Goods, however important, that are superabundant, the supply being unlimited by any cost, have no economic utility or economic value, though to common sense this seems a paradox. The earlier utility or subjective value theorists tended to think of the consumption of any quantity of a particular good as representing or causing a definite quantity of pleasure, and of rational economic behaviour as that which yields a maximum of pleasure or happiness. It is now generally agreed that this is dubious psychology, and that the economic theories had better use the notion of a maximum without trying to say exactly what is maximized—much as the physicist speaks of matter or mass in terms of the way it is measured without trying to define its nature. Perhaps the most important feature of the new views, considered as theories of demand and of price, was not the psychological explanation but clarification of the nature of what Adam Smith called the “effective demand.” It was seen that the demand for a commodity by any consumer or in any market is not a definite magnitude but a functional relation (most commonly represented in textbooks by a descending curve), showing a whole schedule of decreasing amounts that will be purchased as the price is higher. The actual quantities depend on both the desires or tastes of the consumer or consumers and on their purchasing power, and in addition on the availability of other products competing for the expenditure of income, and the prices of these. This idea served to clarify the relation that Smith and his followers had crudely expounded between market price and natural price, now more generally referred to as price in the short run versus the long run. In the former case, the supply is typically the amount already on the market, and the price is the marginal demand price for this amount. But in the longer run, production itself responds to price and price to supply, so that the long-run or normal or equilibrium price is that at which the amount consumers will take is equal to the amount which producers find it profitable to produce. This advance is largely to be credited especially to Alfred Marshall (*Principles of Economics* [1890] and numerous later editions, considerably revised).

Still more important were indirect consequences of the new theories, in connection with supply and cost. One such consequence was a gradual shift of emphasis from wealth to income as the primary fact in economic life and the centre of attention in the science. With respect to price analysis, the earlier economists had recognized—though not clearly or consistently, but N. W. Senior was an exception for clarity—that even in the long run cost affects price only indirectly, by influencing production and supply, hence, as it was now seen, it acts by affecting marginal utility, which is the direct determinant. But the cost of which producers take account is the payments they must make for the productive services they require, and the value of these is derived from, or merely reflects, the value of final products. But with respect to any single product, the costs that must be incurred reflect the value of resources in other uses, giving rise to the principle now generally known as alternative cost, in contrast with the older theory of real cost or pain cost. Subjective sacrifices do play some role, but the correspondence between such cost and the money cost to the producer is very imperfect and the relation may be inverse. (J. S. Mill pointed out that higher paid labour typically involves less pain than lower paid, not more, but he proposed no satisfactory way of meeting this difficulty.) It was also gradually recognized that the costs of production consist of the payments which at the same time constitute the shares in the distribution of the product among the different productive agents. Thus a rational conception of production in terms of the allocation of productive capacity among alternative modes of use, through the competitive bidding of business units (or their managers or entrepreneurs), explains at the same time the prices of final products, the costs of production and functional distribution. Personal distribution depends in addition on the amount as well as the value of the productive services of all kinds that are owned or controlled by the various participants in

economic activity.

Goods are typically produced by the co-operation of various kinds of productive services, and the special problem of distribution, in modern terms, is that of the division of this joint product among the different kinds of co-operating productive services or agents. If only one kind were employed, or even if a number of kinds were always used in fixed proportions the problem would be simple, the value of the productive service (or combination) would obviously be the value of the product. But the fact that goods can be produced by combinations in variable proportions, which sets the problem, also affords the solution. One type of agent can be substituted for another, or the product can be increased or diminished a definite amount by varying the amount of one factor, all others being held constant. This will be clear if one thinks of a farm producing, say, wheat and assumes that the manager uses the three traditional factors, land, labour and capital (embodied in capital goods), however distinguished. But using increasing amounts of any one factor involves diminishing returns. It follows that under effective competition the joint product—of a whole economy as well as of each single enterprise—tends to be divided up in the proportions which measure the efficacy of each factor in increasing the product when the available supplies of all the factors in the economy are used in the way that yields the maximum total product, measured by the economic demand. Around the end of the 19th century a number of writers (especially Philip Henry Wicksteed) pointed out that the principle of diminishing returns, previously applied only to the use of more labour and capital on a given amount of land, is reversible and quite general in application. It governs the competition of different industries and enterprises for given amounts of all the factors, and the historical question whether labour and capital really increase faster than the supply of land is a separate issue and is to be answered only by observing the facts. Hence, under given conditions and under free and frictionless competition, the amount of product assigned (in technical terms “imputed”) to any particular labourer or other agent or unit is the amount which really depends upon the use of that particular agent. A labourer or other agent counts for more and in effect produces more when there is a larger supply of other agents to work with him or it. The amount earned will of course depend on effort and skill and the quality of management, and the real wage or other share will also depend on the prices of the final products for which the labourer or property owner spends the money income he receives. The effort of managers (entrepreneurs) to secure maximum return for their expenditures for productive resources will lead them to buy these in such proportions that at the margin equal expenditures secure equal increments to total product. Any resource will tend to move toward employments where the yield—of a dollar's worth—is highest. And the tendency, again in so far as competition is free and frictionless, is to establish such prices that all dollar's worths of each are of the same value to all employers.

This theory, or principle, that every agent tends to get what it produces does not mean that each person gets what he deserves, and in fact tells us little about the ethical quality or social desirability of the result. It must be remembered that differences in respect of training and of opportunity greatly affect men's productive capacities as workers, and that institutions, especially inheritance, enter into this picture as well as into the ownership of property and the opportunity to accumulate. And the swift process of change in technology and demand often robs men of the fruits of skill acquired at great cost—and also of the savings committed to particular industries. In particular, such innovative activities as invention and exploration for minerals may yield anything from zero to a reward quite disproportionate to the outlay in effort or money. These facts set the general problem of profit, and of its ethical significance. Finally, even when a venture is not undertaken on a gambling chance, various impediments, including the antisocial activities of monopolists, prevent the free mobility of capital and labour from uses of lower to those of higher yield. The doctrine that rewards tend to be proportionate to products is true only as a tendency, but it is

highly important is a corrective to the belief that there is little or no connection, and product itself (value product), to repeat, is no measure or moral desert. The social problems raised must be examined on their merits in terms of ethical principles and the pros and cons of the expediency of political measures. Enforcement of equality may reduce incentive and production, most especially the incentive to take the large risks or chances that always affect innovations. With respect to profit in particular—properly separated analytically from both wages of management and the yield of investment in fairly safe forms—it must be remembered that a prospect of disproportionate gain if successful is necessary if men are to assume voluntarily the risks of loss. The final judgment as to ideal right, and the balance between that and expediency where they seem to conflict, must be left to 'that insidious and crafty animal vulgarly called a statesman or politician' to use a famous phrase of Adam Smith. Experience seems to show however, that considerable taxation of exceptional gains is possible without demonstrably affecting incentives. As just suggested profit, in realistic business usage is a mixed form of income containing elements of interest and of wages for that vaguely distinguishable part of management activity which may be treated as labour, and both the amount of the owner's capital and the proper rate of interest to allow are also uncertain. The distinguishing mark of profit is that its amount is not stipulated in any agreement or fixed in an exchange but is contingent upon the success of a particular enterprise or undertaking. In general profit arises from error, or imperfect foresight, on the part of the responsible entrepreneur, in making policy decisions or in delegating these to salaried managers as his agents (in a corporation the agents of the voting stockholders as a group). Pure profit is the amount left over after making all stipulated payments for productive services, raw materials etc., and after deduction of the going rate of payment for the entrepreneur's own capital and services. It may be a negative as well as a positive sum, and it is impossible to say conclusively whether the gains are greater or less than the losses in the aggregate for a whole economy. Pure profit is of course increased in any individual case by greater accuracy in the ultimate managerial decisions, and tends to be decreased by excessive optimism on the part of entrepreneurs.

The rate of interest has also received much attention in modern discussion. Controversy was stimulated in particular by the publication, in the 1880s of two books by Eugen Boehm von Bawerk, a disciple of Karl Menger. He propounded two views of interest, both adumbrated a half century earlier in the work of N. W. Senior. One is a reworking of the abstinence theory into one of postponement or waiting, or discount of the future. Interest is viewed as the reward or necessary inducement for waiting, hence as the measure of the superior attraction of near over remote enjoyment. The other view regards interest as the yield or productivity of investment due to the greater efficacy of more roundabout processes. Boehm von Bawerk followed the Ricardian notion that capital-goods are produced by labour, or labour and land, it has since been pointed out that co-operation of previously existing capital is also involved and that in terms of value, capital reproduces itself and in addition yields a surplus for consumption or for further investment. The interest rate on loans tends to equal the ratio of the yield obtainable on investments to their amount, i.e., the ratio of the net rental on capital goods (after provision for maintenance and eventual replacement) to their cost, and the cost is the value of consumable goods sacrificed in using productive capacities to create them. When conditions change, after an investment is made the capital which the good represents (its value) is the least cost of producing an item of the same earning power. The psychology of postponement operates by affecting the supply of savings for investment. (See CAPITAL AND INTEREST.) Interest is a form in which the yield of a capital-good (or some part of it) is paid and received, rather than a distinct share in distribution, coming from a distinct source, the lease of a farm or building or other piece of property for a rental achieves the same general result as its sale coupled with a loan, and under perfect competition the choice would be a matter of indifference to both parties. The theory of interest is of the

greatest importance in the general system of value theory, since the value of all durable goods bought and sold is immediately determined by the capitalization of the expected future income. This tends to be the same as their cost since no such good will be produced, or long maintained, unless it is expected to yield at least the going rate on its costs, and if it yields more, new supply will lower the rate. But errors and unexpected changes in conditions often for a time cause capital goods to be worth more or less than cost (to yield less or more than interest on cost). The difference is a profit, or loss.

Methods of Economics—Reference has already been made to the controversy between the critics and the expounders of analytical or theoretical economics—allied in its methods and aims to the older political economy, even when different in content. It is essentially abstract and deductive, proceeding from a few general principles, such as the laws of diminishing returns and diminishing utility, and the uniformity of price to all buyers and sellers in an effective or competitive market. Most of its conclusions can be viewed as cases under a general principle of economic behaviour. The principle is that resources tend to be allocated among alternative modes of use in such a way that they will be equally remunerative in all and so will yield the maximum total return. In another form of statement, it posits an economic man, whose behaviour under given circumstances is completely rational. A free economic order must assume that men actually tend to be rational in the use of means—that they try to be, and tend to succeed. The given circumstances include the wants to be satisfied, the resources themselves, and the modes of use or technology extant in the society at the time. These must be explained or treated mainly by other disciplines than economics. Any science which explains phenomena in terms of measured cause and effect must be abstract, economics (by this method) is often compared with theoretical mechanics, based on frictionless conditions, and the concept of adaptive behaviour in biology is a similar principle, since in fact adaptation is always more or less imperfect. The careful economic theorist does not confuse the abstraction of perfectly economic behaviour, or the economic man, with actual behaviour of real men, any more than the physicist or engineer assumes that friction is absent in real machines. Applied economics must try to take account of the role in business life of error and of motives (good or bad), such as prejudice, curiosity and the various forms of the play interest, which do not conform to the pattern of economic rationality. Competition itself, in the psychological meaning, is a noneconomic interest. The economic interest is merely a striving for efficiency in the use of means, whatever means are available, and whatever ends are pursued. It does operate, at least in modern civilization, in a particularly regular and predictable fashion, and a community whose policies disregard its principles will suffer loss if not disaster. But these principles alone do not make it possible to predict the course of real events or the results of action. They must be filled in with data secured by inductive investigation, as well as qualified to allow for various departures from the behaviour pattern of economic rationality.

Hence it will be evident that the other methods, or approaches to economic data, notably historical research and statistical investigation, are not to be thought of as substitutes for sound theory along the traditional lines, but as complementary to it. This is true also of social sciences other than history and statistics, notably psychology, with or without such qualifiers as social, political, analytic, etc. All are needed to supply data and interpretation to put content and definiteness into the valid but highly abstract laws of economic choice and of market phenomena. Without such supplementation economic laws have little value for prediction, since the essential factor of wants is not open to sense observation and any course of events that occurs can be fitted into the theoretical pattern. The growing accumulations of numerical information covering a wide variety of economic facts, coupled with the advance of statistical technique, have been working a notable change in the character and content of economics as a whole, without nullifying any of its established principles, but giving more knowledge of the actual degree of stability or vari-

ability in the relationships in real life. Interpretation of records covering averages and aggregates and their movements can add much to what can be inferred from common sense principles or observation of particular cases. This does not mean, however, that economics will be or can be purely statistical, a new kind of political arithmetic. The broader the average or aggregate the more heterogeneous the data it covers, and these magnitudes become subject to limitations similar to those of abstract principles. If statistical magnitudes and correlations are to be understood and intelligently used—in guiding such measures as taxation and the regulation of business in the public interest—they must be understood through weaving them into the general structure of our knowledge and relating them to other things we know.

On the other hand, any brief statement of general principles is bound to make economic theories appear thinner and more remote from the concrete facts of economic life than they are. There is a place and a need for all degrees of generality. In recent decades this need has found increasing expression in the developing and spreading study of mathematical economics, in which exposition is made accurate and compact by the use of graphs and of algebraic formulas. In the form of econometrics this movement also brings analytical theory into close alliance with concrete facts, statistically presented. Only by the use of mathematics is it possible to bring together into a single comprehensible picture the variety, the complexity, and most of all the interdependence, of the numerous factors which determine prices, costs, output and demand and the wages or hire of productive agents. The mathematical treatment of economic principles was first successfully undertaken by the French economist, mathematician and philosopher, Antoine Augustin Cournot (*Recherches sur les principes mathématiques de la théorie des richesses*, [1838]). Elaborate mathematical formulations of the conditions of general economic equilibrium have been worked out, notably by Walras (*Elements d'économie politique pure*, [1874-77] and later editions) and his follower Vilfredo Pareto (*Manuale di economia politica* [1906] and other works). The principal value of such elaborate and abstract systems lies in forcibly reminding the enquirer that a change in practically any economic variable has direct or indirect effects on innumerable other magnitudes, and so preventing him from fatally oversimplifying conceptions of economic cause and effect. Other writers, notably Alfred Marshall, adopted an intermediate position. Marshall was a competent mathematician, but used and advocated the literary form of exposition (contemptuously so named by Pareto), relegating the mathematics to footnotes and appendices in his monumental work. He also emphasized the interdependence of economic phenomena, but centred his attention on the relations between the more closely connected factors, the relations of greatest practical import, in contrast with system building. But his successors, of the Cambridge or neoclassical school (notably A. C. Pigou), were impelled to make more direct use of mathematics in their exposition, and the study and use of algebra and calculus spread rapidly among economists in all countries. And, in line with the older classical tradition, the science places increasing emphasis upon factors which make for change and disequilibrium, as well as those making for stability.

Problems of Present Day Economics—Since all general principles are necessarily abstract, the more theoretical parts of economics cannot be taken to be a complete and adequate account of the mechanism of modern economic life. They afford serviceable approximations to partial, but important, aspects of the truth, and the study of history and factual data yields other true and important generalizations. Even in their present imperfect and incomplete state the generalizations an economist has at hand constitute an organon of proved effectiveness, an instrument by means of which some of the results of economic changes, whether planned or not planned, may be predicted with a fair degree of certainty. New problems constantly appear and challenge attention, as facts change and new interests emerge, and different groups of problems have their special literature and engage the attention of corps of specialists. The most striking and possibly the most important characteristic of recent work in economics,

as contrasted with the older, is its greater realism. It does not attempt to do without abstract conceptions, but it does attempt to take these from the world of affairs, or bring them into line with facts.

This trait is conspicuous in the treatment of the two great practical problems or groups of problems which have particularly forced themselves on the attention of the public and of statesmen and economists in roughly the past two generations. These problems centre respectively in the growth of large scale corporate business and associations of firms which concentrate power and tend to exploit the public through monopoly and high finance (and labour problems are related to these), and in the mechanism of money and credit commonly held responsible for the recurring phenomena of industrial fluctuations or business cycles, with their attendant wastes and hardships. Depressions and the measures taken by different countries for dealing with them, in connection with the impact of two world wars, have also intensified interest in international economic relations affecting money and capital movements and trade in general, and in tariff duties and other devices for controlling it. The depression of the 1930s and World War II generated a world wide movement toward state control or planning of economic life, and particularly toward use of quotas on imports and strict control of foreign exchange, and even governmental conduct of foreign trade. In none of these fields is the ground completely explored or all the issues settled, but findings have been reached which appear to have permanent value. The outcome of the various fiscal and monetary measures to which governments have resorted, and the results of the restrictions imposed upon trade and industry have in general been about what competent economists predicted, and this is true of the experience with reparations and monetary stabilization after World War I. The tendency has been to confirm long established principles, though political considerations have made it difficult for governments to learn, or at least for them to apply, the lessons taught. This fact is especially prominent in connection with the perennial issues of protection in international trade, and of inflation, through cheap money or credit. Inflation is tempting as an easy way to finance a government at war or under special financial stress from any cause and as a way to achieve a bogus prosperity, not to mention the fallacy of making capital cheap and lightening the burdens of debtors through an abundance of money. (But inflationary measures may be justified to counteract deflation and relieve depression.)

The general form given to economics by the early classical writers was determined very largely by preoccupation with certain special types of problems, notably problems of national commercial policy. Recent events have brought this group of problems again to the fore and later experience and discussion, while confirming earlier views in a general way, have led to some modification. The older economists, in their efforts to dig beneath that surface view of economic life which had deceived the mercantilists, held that money is merely an instrument or tool. They carried this idea to extremes, though in some types of pure economic theory today it is found convenient to go still further and assume that trade is conducted by barter, without the use of any special medium of exchange (all commodities having equally the character of money). But the phenomena of inflation and deflation and of boom and depression, have forced modern economists to recognize that the use of money and credit has important effects on the character of effective demand and on production and distribution. Quite naturally, the great depression of the 1930s gave a tremendous impetus to discussion in this field, and its importance was further enhanced by the fear of depression, or boom and then depression, to follow World War II, and by measures taken or proposed in this connection. A landmark in this discussion was the publication, in 1936, of a book, *The General Theory of Employment, Interest and Money*, by John Maynard Keynes, of Cambridge university. Fuller treatment of these issues is given in other articles. It must suffice here to note that the discussion has at least called attention to one fact. The famous "law of the market" (often called "Say's law" from its formulation by the great French economist) stating that the demand for any good

is the supply of other goods, and the supply of any one is the demand for others while a truism for a barter system is not valid in the short run in a complex monetary economy. And further, the short run may be both longer and more important than is likely to be inferred from the orthodox or neoclassical expositions of economic theory. In emphasizing the nature and conditions of a theoretical equilibrium, these writers have tended to undue neglect of changes in monetary circulation (hoarding and dishoarding, or changes in the quantity of money or substitutes, such as bank credit, or its velocity of circulation) and their often serious and protracted consequences. In particular, it cannot be assumed that monetary saving will be followed automatically and immediately by investment. The funds need not be offered on the loan market, and if they are offered they may not cause a sufficient decline in the long-run interest rate to cause real investment, since this depends largely on speculative anticipations and these in turn often depend more on conjecture and mass psychology than on definite knowledge and rational calculation of future prospects. In consequence, production of capital goods, particularly the more lasting forms, including durable consumption goods, may decline heavily, and unemployment in these industries will cause shrinkage even in the industries producing for immediate consumption.

Even if it is admitted, as it doubtless must be, that if all prices were immediately and uniformly responsive to monetary changes, this is not what happens in reality. In particular, monetary wages are "sticky," and are especially resistant to downward movement. And wages are the largest factor in production costs, and notably in the variable and marginal costs which are most influential in producers' planning. Thus wage policy becomes a crucial factor in the problem. There is a real danger, even a probability, that reduction of wage rates may reduce total disbursement of purchasing power in the field of consumption, which may react seriously on the effective investment demand. Drastic action in the direction of inflation (or deflation, a word that came into use in the early years of the great depression) may be the only feasible way of counteracting the tendency to a downward spiral. The appropriate methods and instruments of such action came to occupy a large place in the discussion and controversy set in motion by the distress of the 1930s and particularly by Keynes and his followers and opponents. Accentuation of issues in international economic policy was another result, which can only be mentioned here, the need for any country to protect itself against economic repercussions abroad runs into measures open to the accusation of exporting unemployment, and in the absence of wise concerted international action they certainly tend to aggravate the situation.

One of the conspicuous phenomena in recent economies has been intensified activity in the field of labour problems, already mentioned as a development consequent upon the labour movement of the 19th century and after, connected with the growth of large corporations and other forms of unified action among business interests. Up to the last quarter of that century there was little careful analysis of those problems, apart from discussion of the general theory of wages under some approximation to free competition. Now however, there is hardly a field of economic inquiry which is more thoroughly cultivated, or in which there is more controversy. It runs into the general problems of economic planning and socialism. The labour union movement and its significance, the pros and cons of collective bargaining, the length of the working day, factory legislation, profit sharing, the organization of control within the enterprise, labour turnover, the legal minimum wage, the prevention and settlement of industrial disputes, compulsory arbitration and social insurance in its various forms, as well as the causes of unemployment and its possible remedies, are all burning issues in both economic science and practical politics.

It is important to observe that all these practical problems have been brought into the scope of economics by the course of change in economic and business life, the attention now given to them does not mark a change of attitude or general social position among economists. The earlier thinkers, in response to the conditions and needs of their times, at the beginning of the modern industrial era, were primarily concerned with exploding popular fallacies with respect to the ways in which the prosperity of the community can best be secured and, with that end in view, in showing how the economic activities of individuals may work together, through the open market, and be so interrelated as to constitute a great communal economic mechanism. Under the circumstances, they were more concerned with what governments could not or should not do than with what they could wisely attempt. Thus they often gave the impression—an impression which careful study of

the writings of the ablest of them will dispel—that they regarded that mechanism as all-sufficient, needing neither interference nor direction on the part of the community. While the need for a better understanding of the theory of the open market organization and better appreciation of its merits is still present, modern economics tends to strike a different note. Its tone is less negative, it is more insistent in its search for and scrutiny of possible ways of altering for the better the organization of the community's economic life, which has remained on guard against the dangers of disaster from unforeseen results of wrong lines of action. Since almost every gain has its cost, most of the problems resolve themselves into a question of a balance of advantage. But the advantages and disadvantages are hardly ever purely economic and therefore no analysis in terms of purely scientific economics can completely dispose of such questions. Political, social and ethical ideas and issues must also be taken into account, and economists are showing an increased awareness of these broader considerations. The economist, however, may gauge the general character of the probable effects of a specific measure upon production and distribution, and so make it possible to discuss the wisdom of any proposed action in the light of its probable consequences.

In connection with this shift of emphasis an important factor is the vast accumulation of more—and more reliable—factual data. Reliable records of economic activities, or at any rate of their results, are now brought together and published by governments and by business and other private organizations, on a scale which would have excited the envy of the earlier economists. A much wider range of economic experience is now available for study and analysis. In dealing with this new material—a sense of the product of these activities which it records—economics is impelled toward a more realistic and concrete view. It has to deal with economic events in the forms in which they actually occur, and to search for the systematic relations which run through the mass of real events. But although the interests of economics have become more varied and concrete, and although economists have become better adapted to handling the facts of economic life as those facts present themselves, economics remains a political or social science and also, in the old sense as well as new senses, a theoretical discipline. Particular findings or tenets have been discarded and replaced, or fundamentally re-stated, and sweeping additions have been made. But the general picture of a scheme of communal economic life remains a picture sufficiently ordered to be useful for analysis and prediction, though imperfect enough to give point and purpose to its continued study, elaboration and refinement, in spite of changes of viewpoint and of method.

BIBLIOGRAPHY—A. E. Monroe, ed., *Early Economic Thought* (1924) contains well chosen excerpts of adequate length from 16 economic writers of period before Adam Smith. S. H. Patterson, ed., *Readings in the History of Economic Thought* (1932) contains a series of essays from Smith onward. Paul Gsell, ed., *Les grandes économistes* (1925) covers both periods, excellent bibliographies. On the history of the period before Smith the best general reference is August Oncken, *Die Geschichte der Nationalökonomie*, 3rd ed. (1922). For the later period, Charles Gide and Charles Rist, *History of Economic Doctrines*, tr. from the French (1948) and William A. Scott, *The Development of Economics* (1933) are similarly useful. Recent literature is treated in detail in Theo Suranyi Unger, *Economics in the Twentieth Century*, trans. and rev. from German ed. of 1927 (1931) and, more critically, in Hans Mayer, F. A. Fetter and R. R. Ruch, eds., *Die Wirtschaftstheorie der Gegenwart*, 4 vols. (1927-32). On special periods or aspects: George O'Brien, *An Essay on Medieval Economic Teaching* (1910); E. H. F. Heckscher, *Merchants*, 2 vols. following Swedish and German editions (1935); Edwin Cannan, *A History of the Theories of Production and Distribution in English Political Economy, from 1776 to 1848*, 3rd ed. (1924); S. P. Altmann and others, *Die Entwicklung der deutschen Volkswirtschaftslehre im 19ten Jahrhundert*, 2 vols. (1908); James Bonar, *Philosophy and Political Economy in Some of Their Historical Relations*, 4th ed. (1922); Walter Bagehot, *Economic Studies* (1886); T. E. Cliffe Leslie, *Essays in Political and Moral Philosophy* and ed. (1888); William Stark, *The Early Foundations of Economic Thought* (1941); E. R. A. Seligman, *Ideas in Economics* (1924); G. H. Bousquet, *Essai sur l'évolution de la pensée économique* (1917); Othmar Spann, *The History of Economics*, Eng. trans. from 19th, Ger. ed. (1930). The following are standard treatises: J. K. Ingram, *History of Economic Thought*, rev. ed. (1923); L. H. Haney, *History of Economic Thought*, 3rd ed. (1936); Hector Denis, *Histoire des systèmes économiques et socialistes*, 2 vols. (1904-1907); Charles René Gonnard, *Histoire des doctrines économiques*, 3 vols. (1921-22); Joseph Schumpeter, "Epochen der Methoden- und Dogmengeschichte," *Grundriss der Sozialökonomik*, vol. I (1924); E. H. Roll, *A History of Economic Thought*, 2nd ed. (1947); Edmund Whittaker, *A History of Economic Ideas* (1940). For a general characterization of contemporary economic theory, see Lionel Robbins, *An Essay on the Nature and Significance of Economic Science* (1932), and T. W. Hutchison, *The Significance and Basic Postulates of Economic Theory* (1938). Articles on special topics and individuals with bibliographies, will be found in the *Handwörterbuch der Staatswissenschaften*, 4th ed., 8 vols. (1911-28), also in the *Dictionary of Political Economy*, edited by Sir R. H. I. Palgrave (revised ed., edited by Henry Figgis, 3 vols. (1926)) and in the *Encyclopaedia of the Social Sciences*, ed. by E. R. A. Seligman and Alvin Johnson, 15 vols. (1930-35), 2d. issued, 8 vols. (1937). (F. H. K.)

ECONOMICS, PRIMITIVE Comparatively little is known about the economic organization of savage peoples. Being apparently one of the simplest and least interesting aspects of their social life, it has been the last to receive attention from the anthropologist, though in reality it presents complex problems of vital concern for native welfare. Most of our knowledge of the principles of savage economic life is due to the work of German scholars. The earliest studies in economic anthropology were largely of an evolutionary nature, attention being concentrated on the somewhat barren aim of fitting phenomena into schemes of stages of progress and constructing theories of development from one stage to another. Best known of all is the *Dreistufenschema*, the three stage scheme of society by which mankind, having first lived as hunters and fishers, advanced through the pastoral grade of existence to attain the state of agriculture, which represented the final achievement of primitive industry. This scheme of the economist Friedrich List persisted for several decades, though the idea of a universal course of evolution for all mankind soon disappeared. Rival theories, as that of the barter, money, credit periods of development of Bruno Hildebrand, were also advanced. In time the old three stage pattern of economic progress was abandoned, owing to the destructive criticism of geographers such as Friedrich Ratzel and anthropologists like Eduard Hahn. Other schemes of classification of culture, associated with the names of Hahn, Ernst Grosse, Alfred Vierkandt and Heinrich Schurtz, came in rapid succession, but the value of such work lay in the collection of data and the incidental analysis of native economic conditions—as in Hahn's distinction between hoe-cultivation and agriculture proper with plough and domesticated animals—rather than in the actual theories propounded.

The writings of Karl Bucher, by drawing the economy of primitive man into relation with that of our civilization, have done much to provoke interest in the subject. His classification, however, of all savage economic life as being either a selfish individual hunt for food or at best a sharing of goods within the closed circle of the household, does not conform to the facts as now known, nor do his theories of the development of exchange from the custom of giving presents and the origin of work in play find much modern support.

Exponents of the *kulturhistorische* method in anthropology, notably Wilhelm Koppers, have also laid due stress on the economic factor as a prime determinant of culture. But their study of economic life is made subservient to their attempt to establish certain theories regarding the history of mankind which involve a hypothetical scheme of *kulturkreise* or stages of culture. This interest in the problematical origins of native custom has led to a neglect of its real place in native life.

Studies by such writers as M. Marcel Mauss, Prof. Richard Thurnwald and Dr. Bronislaw Malinowski have done much to retrieve the position. The attempt to establish evolutionary sequences has been discarded, and the imagined history of institutions left on the side. Primitive economic organization is studied for its relation to the existing social mechanism, for the ends which it serves in the present, not for what it may have been in past ages. In short, the "functional method" of inquiry is employed. The institution of the exchange of gifts, for example, is shown to be part of the native economic system, not in virtue of being a transition stage from gift making to trade, but because it satisfies certain practical needs and allows for the expression of social sentiments—ideas of rank, prestige, liberality and fulfillment of obligation. Recent work of this type in primitive economics has thrown light upon such questions as the character of leadership in native labour, the social stimuli involved, the part played by co-operation, the nature of economic reward, the action of the principle of reciprocity in exchange, the value of magic in industry, and the influence of wealth upon chieftainship and rank.

Such problems are concerned with vital issues, and the investigator here is grappling with the reality which lies at the foundation of the life and work of the native. Such study, apart from its interest to the economic historian in throwing light on

the nature of less developed forms, portrays the land and sea and practical value. An adequate knowledge for a distance of about 100 miles of a native people is essential before the river on which is traded with them, utilize their labour, secure gulf and its northern political affairs, or preserve them from the numerous estuaries contact with white civilization. the Estero Salado

ECONOMIZER An important adjunct to a steam generator plant. Instead of being allowed to escape to the chimney direct from the furnaces, the waste gases are led through passages in

DIAGRAM TO SHOW PASSAGE OF WASTE GASES FROM BOILERS WHICH ARE MADE TO HEAT WATER IN ECONOMIZER BEFORE ESCAPING BY CHIMNEY

which are placed sets of vertical tubes. Water passes through the tubes and the heat of the gases raises it to a useful temperature for various purposes, not merely to supply the feed for the boilers, but also for supply where a large quantity of hot water is required, as in laundries, hotels, breweries, dyeworks and so on. At the same time, strains on the boiler plates and parts through exposure to an inflow of cold water are prevented. Scale trouble in the boiler is also greatly reduced, because the scale forms instead inside the economizer tubes, and these are readily cleaned. About 15% to 20% of coal is saved on the installation of an economizer. Evidence of this is found in one example of an economizer for which the gases leave the boiler at 650° F., the feed water entering the economizer at 100° F. leaves it at 272° F., reducing the temperature of the gases to 330° F. The Green economizer consists of a number of vertical cast-iron tubes, 4½ in. external diameter, made up in sections, and connected with branch pipes at top and bottom. The outside of each tube is kept clean by encircling scrapers, which travel slowly up and down all the time, actuated by automatic mechanism at the top. The soot falls into a pit for convenient removal. There is also a horizontal type of economizer which is mounted above a water tube boiler. In some designs of economizers tubes with gills are used, to obtain the maximum heat transference, and the soot is cleaned off by steam blowers.

ECONOMY, the thrifty management of the financial resources of a household or of an individual, hence a "saving," not only of money, but of time, labour or effort, and generally, the least expenditure of means to attain a required end. "Economy" is also used in theology in such expressions as "Mosaic" or "Christian economy" as a synonym of "dispensation," for the administration of the world by God at particular times or for particular races. From the meaning of organization or administration of a house or State the word is applied more widely to the ordered arrangement of any organized body, and is equivalent almost to "system"; thus the "economy" of nature or of animal or plant life may be spoken of. "Political economy" is the science dealing with the production, distribution and consumption of wealth (see ECONOMICS).

ECORSE, a village of Wayne county, Mich., U.S., on the Detroit river, 7 mi SSW of Detroit. It is served by the Detroit, Toledo and Ironton, the Michigan Central and the New York Central railways. The population was 17,571 in 1950 and was 13,209 in 1940 by the federal census. It is an industrial suburb of Detroit. The village was founded about 1812 and was incorporated in 1902.

sometimes reaches 2,600 ft altitude

The *montañas de Cajas* in the western part of the province of Esmeraldas, lie between the Pacific and the Rio Quinde. These "mountains" are a narrow ridge about 35 mi long and reaching 1,000 ft altitude. Just southeast of the town of Esmeraldas is a narrow ridge called *montañas de Atacames*. It is about 20 mi long and its summits attain an elevation of nearly 1,000 ft above the sea.

Scarcely anything is known of the coastal region between the rivers Esmeraldas province is supposed to be a tableland having summits of about 1,000 ft elevation and valleys dissected to nearly sea level. The Guayas river and its tributaries form a large part of the coastal region. The river is in part an estuary extending north from the Gulf of Guayaquil and is the largest navigable stream on the Pacific coast of South America. At Guayaquil to which seagoing vessels ascend it is about 2 mi wide. The river rises near the equator, and its main tributaries are the Daule, the Vences, Rio Zapotal and Rio Chimbo, all navigable on their lower courses and having extensive swamp areas. Steamboats go regularly from Guayaquil up the Rio Bodegas to Babahoyo 80 mi above Guayaquil and for 40 mi up the Daule. The navigable channels of the Guayas and its tributaries are computed to be 200 mi long, the drainage basin is said to cover about 14,000 sq mi. The second large river system of the coastal region is the Rio Esmeraldas, which like the Guayas has tributaries whose sources are in the snows of the Andean highlands. The Rio Esmeraldas is formed by the Guallabamba and Blanco about 42 mi from its mouth and discharges into the Pacific at 1° N and 79° 40' W through a narrow and precipitous gorge. The most northerly important coastal river system is the Santiago, formed by the Cayapas and the Santiago. The Cayapas is navigable by canoe for a long distance, the Santiago for only a few leagues above its junction with the Cayapas. Below La Concepcion, the Santiago is a broad, deep stream. Near its mouth it divides and forms many islands, chief of which are La Fola, Santa Rosa and San Pedro. The Mira, north of the Santiago, forms for a part of its course the boundary between Colombia and Ecuador.

Bays.—The coast extends from about 1° 30' N and 78° 55' W to lat 4° 35' S and curves westward to 81° W. Most prominent headlands are La Puntilla, Cabo de San Lorenzo, Cabo Pasado and Punta Galera. The bays are commonly broad indentations with the exception of the gulf of Guayaquil, and the rivers discharging into them are generally obstructed by bars so that the small ports of the coast do not afford much protection to shipping. The most northerly of these bays is Ancón de Sardinias, lying south of the Mira delta. The head of the bay is fringed with islands and reefs behind which is the mouth of the Mataje, the boundary between Colombia and Ecuador, and that of the Santiago. The small bay of San Lorenzo would form an excellent port terminus for Quito. The coast for about 80 mi E and W of the mouth of the Esmeraldas consists of rocky promontories and of high cliffs broken here and there by short river ravines. The Esmeraldas has a wide mouth with islands and shoals constantly altered by the swift current. The port of Esmeraldas is on the left bank of the river. As the mouth is obstructed by a bar and the river current is swift, the anchorage for ships is outside in an open roadstead with slight protection. Between Cabo Pasado and Cabo de San Lorenzo is a broad indentation in which is the Bahía de Caraquez, a small bay, now the terminus of a railway which runs inland 47½ mi to Chone. The southern portion of the broad indentation is called Bahía de Manta and on this is a small port served by a railway extending inland 37 mi to Santa Ana. The Bahía de Santa Elena is formed by a broad curve from Punta Ayacucho to La Puntilla. At Salinas a small settlement on the end of the point "La Puntilla" is the landing place of the All-America cable. A pipe line terminates on the shore east of Salinas bringing petroleum from the wells of the Anglo-Ecuadorian Oil Co., situated on the south coast of the peninsula. Ships anchor with little protection in the roadstead between Salinas and Balenita. The gulf of Guayaquil is the largest on the Pacific coast of South America. Its mouth is 140 mi wide between La Puntilla on the north and

Cabo Blanco on the south and it penetrates the land eastward with a slight curve northward at its head for a distance of about 100 mi, terminating in the Guayas estuary and river on which is the port of Guayaquil. The upper end of the gulf and its northern shores are fringed with swamps through which numerous estuaries penetrate for some distance inland. Of these, the Estero Salado west of the Guayas, formed of many shallow tide water channels, penetrates as far inland as Guayaquil, but is used only by canoes. Near Guayaquil in the Estero Salado is good bathing. The upper end of the gulf of Guayaquil is filling up with the silt brought down from the Andes. It is divided midway by the large island of Puna, at the eastern end of which is the anchorage for steamers too large to ascend the Guayas. The steamship channel passes between this island and the Peruvian coast and is known as the Jambeli channel. The Morro channel west of Puna, is obstructed by shoals and is dangerous for shipping. In the Jambeli channel on the southeastern shore of the gulf is the small port of Puerto Bolívar, serving Machala and the Zaruma mining district.

Islands.—There are few islands off Ecuador, and only one of any considerable size that of Puna in the northeast part of the Gulf of Guayaquil. This is 29 mi long by 8 mi to 14 mi wide. Puna generally is low and swampy and its shores, except on the east, are fringed with mud banks. It is densely wooded, in marked contrast to the opposite Peruvian shore and is unhealthy the greater part of the year. It has a population of about 3,000, about 800 living in the village of Puna at its northeastern extremity. Pilots are taken on there to ascend to Guayaquil. Twelve miles southwest of Puna island and 80 mi from Guayaquil is Amortajado (or Santa Clara) island, whose resemblance to a shrouded corpse suggested the name which it bears. It rises to a considerable elevation, and carries a light 256 ft above sea level. There are some low, swampy islands, or mud flats, covered with mangrove thickets, in the lower Guayas, but they are uninhabited. On the coast north of the Gulf of Guayaquil there are only two small islands of more than local interest. The first of these is Salango, in 1° 35' S, which is about 2 mi in diameter and rises to a height of 524 ft. It is well wooded, and has a well sheltered anchorage formerly frequented by whalers in search of water and fresh provisions. The next is La Plata, in 1° 16' S, which rises to a height of 790 ft, and has a deep anchorage on its eastern side where Drake is said to have anchored in 1579 to divide the spoils of the Spanish treasure ship "Cacafuego." The Galapagos Islands (g's) belong to Ecuador, and form a part of the province of Guayas.

The Amazon Region.—The region east of the Andes mountains or the Amazon region is called the Oriente and is entirely forested. It begins at the eastern base of the Andes mountains which may be taken at about 4,000 ft above the sea, and the southeastern portion of the region was involved in the frontier dispute with Peru (see above on boundaries).

The land surface in general slopes eastward, at first rapidly until at about 850 ft above the sea it becomes a part of the Amazon lowland. Very little is known of the interstream areas. Immediately east of the Andes the general surface is deeply dissected by rivers, but in a measure as one proceeds eastward the land surface tends in general to meet the level of the rivers. Near the Andes are here and there mountainous masses like the volcano Sumaco (12,490 ft above the sea) and the cordillera Galeras which in reality belong to the Andean region for they are connected to the Andes by the 4,000 ft contour. A few detached mountain masses such as the Lumbachi mountains on the equator in longitude 77° 20' west of Greenwich are known to exist and doubtless others will be discovered later.

The main rivers of the Oriente originate on the Andes. All flow into the Atlantic and those whose sources are in the Andes emerge in great gorges on to the Amazon lowland. They are torrential and not navigable till they reach a low elevation when they suddenly become navigable, not only for canoes, but for launches and steamers.

This uppermost point of navigation, or fall line is clearly marked. The streams for about 100 mi east of the Andes are torrential and full of rapids. Their courses in this part are usually

"braided", i.e., choked with debris from the Andes so that there are many channels and islands. The beds are of boulders which decrease in size eastward. At the fall line which on the Rio Napo for example is 850 ft above the sea in longitude 77° 00' W of Greenwich, and about 3,000 mi from the Atlantic, the braided character disappears and the rivers become deep sluggish and wide, with low mud banks.

Tributaries.—The streams are all tributaries of the Amazon (qv) divided into two classes, those which rise in the Andes and those which have their entire courses east of the mountains. In the first class are the Rio Napo, Rio Pastaza, Rio Santiago and Rio Chinchipe. To the second subdivision belong the Rio Tigre and the Rio Morona. The Rio Napo, the tributaries of which rise on the Andean slopes from Cotacachi north to Tulcan, is the largest of these rivers. Its total length is about 700 mi and it enters the Amazon at about 385 ft above the sea, in lat 3° 20' S and long 72° 40' W of Greenwich. From the village of Napo near the base of the Andes where it has an elevation of 1,580 ft above the sea, it descends in 90 mi to an elevation of about 900 ft above the sea, at the mouth of the Rio Coca. From there it drops 515 ft in about 464 mi or about one foot per mile. In the stretch between Napo and the mouth of the Rio Coca, the river is shallow and canoes can be used but going upstream against the current and with bad rapids, it is slow work, about 14 mi per hour. The descent from Napo to the mouth of the Coca is done by canoe and by shooting the rapids, in two days, i.e., at the rate of about 5 mi per hour. At the mouth of the Coca, the Napo is about 1,500 ft wide, at its mouth it is nearly one mile wide. Steam launches can ascend to a point several miles above the mouth of the Rio Coca. The principal tributaries of the Napo are the Aguacico and the Coca from the north, and the Curaray from the south. The Coca unites with the Napo in lat 0° 30' S and long 77° 00' W of Greenwich and is about 150 mi long. This river was explored by J. H. Sinclair, who found that at Papallacta it is about 10,333 ft above the sea and at Baena 20 mi farther east, 5,863 ft having a fall of about 213 ft per mile in this distance, a total of 4,470 ft.

The main tributary of the Napo from the south is the Rio Curaray. This stream rises east of the Andes 18 mi north of Canelos. This stream rises east of the Andes 18 mi north of Canelos, in hills about 2,000 ft above the sea. It is about 400 mi long and joins the Napo about 143 mi from the Amazon. Near its headwaters it is a creek with a serpentine course and it is described as having this feature all the way to its mouth. It is said to be navigable on account of its sluggish current as far as Canelos, about 300 mi from its confluence with the Napo. Sinclair crossed it in 1921 in long 77° 40' W of Greenwich and gave its elevation there as 2,000 ft above the sea with a fall of about 5 ft per mile.

The Rio Pastaza which is about 450 mi long enters the Amazon at a point 76° 20' W of Greenwich and about 4° 55' S lat. The upper portion of this river, 127 mi long lies on the Andean highlands and has been described above as far as Mera, 1,808 ft above the sea where the river enters the Amazon lowland. From Mera the river drops at the rate of 40 ft per mile to the mouth of the Rio Pindo (2,700 ft above the sea), where it is still a torrential stream. Apparently the river is not navigable for canoes above Andoa, a settlement about 68 mi below the Pindo, for the usual route of Indians and travellers eastward leaves the Pastaza near the mouth of the Pindo, to proceed overland to Canelos (1,690 ft above the sea, in lat 1° 35' S and long 77° 45' W of Greenwich) on the Rio Bohonaza where canoes are taken to its confluence with the Pastaza at Andoa, a point about 216 mi from the Amazon. It is said that boats of a draught not exceeding 4 ft may ascend about 110 mi from the Amazon.

The Tigre is an affluent of the Amazon and rises east of the Andes. Its length is a little over 400 mi. It joins the Amazon in 73° 55' W of Greenwich and in 4° 20' S lat. It is navigable for boats drawing 6 ft at high water from the confluence of its tributaries, the Cunambo and the Pintuyacu, to its mouth, a distance of about 400 mi. About 104 mi from its mouth it receives the Rio Corrientes, an affluent from the west which is navigable for about 100 mi. The Rio Pucacuri joins it from the north about 152 mi from its mouth and this latter stream is navigable

it is said for about 37 mi above its mouth. The width to the mouth of the Corrientes is 650 ft to 980 ft and its depth from 25 ft to 30 ft. The current is said to flow at about 15 mi per hour. The ascent of 400 mi can be made in about 67 hr, there being only two bad places, the Island of Tacuma and at Piedra Lisa.

The Morona is an affluent of the Amazon, whose course is also entirely on the lowlands east of the Andes. Its sources are said to be in the Rio Cumasi and other streams north of Macas at elevations of about 4,000 ft above the sea. Its length is about 340 mi. It joins the Amazon at 485 ft elevation in longitude 77° 02' W of Greenwich and 4° 45' S lat. It is a meandering river and at 243 mi from its mouth is only 660 ft above the sea, 203 mi further down its elevation is 515 ft and the fall is thus only 144 ft in 203 miles. From there to the mouth, 41 mi, the drop is only 30 ft. It is navigable from its mouth to the Manahuasí, 110 mi upstream at all times and for two thirds of its length by steam launches drawing 4 ft. Its depth is from 40 ft to 50 ft and its width from 260 ft to 490 ft.

The Rio Santiago empties into the Amazon in 77° 38' W of Greenwich and 4° 25' S lat at an elevation of 580 ft above the sea. Its mouth is just above the Pongo de Manseriche. Its total length following the tributary Rio Zamora is 281 mi, the Rio Zamora being 150 mi long. From Macas, 3,580 ft above the sea, on the Rio Upano, to the mouth of the Santiago, 580 ft elevation, the distance is about 182 mi and the drop 3,000 ft, i.e., about 16 ft per mile.

The Rio Chinchipe is about 88 mi long and is almost entirely in the Andes. It joins the Amazon in 5° 27' S lat and long 78° 32' W of Greenwich at an elevation of about 1,209 ft.

(J. H. S. K., X.)

Geology.—The Andes reach great heights in Ecuador, where they include several lofty volcanic peaks. The volcanoes are of Tertiary or later origin and are most numerous in the northern half of the country. Cotacachi, Chimborazo and Cayambe are volcanoes that rise more than 10,000 ft above sea level, and these and other snow covered and ice capped peaks form the culminating points of the mountain mass. This has been divided into the Eastern cordillera, composed of gneiss, mica schist and other old crystalline rocks, and the Western cordillera, composed of porphyritic eruptive rocks of Mesozoic age and of Mesozoic sedimentary beds, mainly Cretaceous. Between these ranges are recent deposits that contain plant remains. Northward this depression is in large part filled with lava, tuff and agglomerate from the volcanoes, which stand either upon the folded Mesozoic beds of the Western cordillera, on the old rocks of the Eastern cordillera or on the floor of the depression. The lavas and ashes are mostly Andesitic. Ecuador is more subject to volcanic disturbances than any other South American country, excepting perhaps Chile.

The mineral resources of Ecuador have been only slightly developed. Gold, mercury, copper, iron, silver and lead are mined. Platinum was discovered in the Santa Elena peninsula, north of Guayas Gulf. The largest development is that of gold, centring around Zaruma in the province of El Oro. Some sulphur deposits exist in the Pichincha and Chimborazo districts, and in the Galapagos Islands. There is coal in the interior of the republic. Ecuador has important petroleum fields, the coastal region of the Santa Elena peninsula, the Amazon country in the east and the Andean plateau.

(G. McL. W. S., X.)

Climate.—Were it not for its lofty mountains and the Humboldt current the climate of Ecuador would be entirely tropical, for it is traversed by the equator. But, inasmuch as the elevations extend from sea level up to 20,576 ft, the climates vary from the tropical of the lowlands east and west of the Andes, through the temperate of the higher slopes, to the Arctic climate of the peaks of Chimborazo, Cayambe, Antisana, etc.

The tropical lowlands are along the Pacific coast and the tributaries of the Amazon, east of the Andes. The former are comparatively dry, the latter extremely humid because of the Atlantic trade winds in their southwestern course across the low and extremely wet basin of the Amazon.

The Pacific coast is one of transition between the arid climate of the coast of Peru to the south and the northerly humid one of

Colombia. The former climate is caused mainly by the presence of the Humboldt current which flows from the coast of Chile north, and the latter by the warm south flowing waters of the Central American current. These two currents, with a difference of temperature of from 6° to 8° F., meet off the coast of Ecuador and flow west to the Galapagos Islands. Only at rare intervals is their relative strength altered, as in 1925 when the Central American current flowed farther south than had ever been known and the Humboldt current appeared to be missing entirely. Consequently the deserts of Peru and of southern Ecuador were visited by large quantities of rain for the first time in many years.

Under normal conditions, the inner shores of the Gulf of Guayaquil, the island of Puna, the valley of the Guayas and all the coast of Ecuador north of Cape San Lorenzo have considerable rainfall, while the coast from the Santa Elena peninsula north to Cape San Lorenzo, including the island of La Plata, is a region of scanty rainfall. From Cape San Lorenzo south there appear to be four climatic provinces. In the Montecristi region the climate is normally semiarid but the hills receive a typical heavy Scotch mist. In the *cordillera de Colonoche*, a ridge about 1,800 ft high south of the above region, there is more humidity and very thick vegetation. In the Santa Elena peninsula there are no hills and the climate is extremely arid. Finally along the shore of the Gulf of Guayaquil southeast from Santa Elena the climate is tropical with luxuriant and profuse vegetation. The Santa Elena climate is characteristic of the arid type.

There seems to be a clearly marked division in the Pacific coastal region into cooler months from July to November and warmer months the rest of the year. The tropical region east of the Andes is the zone of greatest rainfall.

Flora.—The flora varies from that of the tropics to that of icy mountains, from vegetation characteristic of humid and arid regions on the Equator to lichens on the snows at 18,400 ft above the sea. Corresponding to the broad climatic divisions the vegetation is classified into five types: (1) that of the arid regions on the low-lying Pacific coast, (2) that of the humid regions on this same coast and in the low lying Amazon region east of the Andes, (3) that of the forests on the eastern and western slopes of the Andes up to about 10,000 ft altitude, (4) that of the so called "cereal" zone, a treeless region on top of the Andean plateau, and (5) the *paramo* or Alpine region which terminates in the region of perpetual ice and snow. Because of this great diversity of climate, the flora of Ecuador is exceedingly rich, and species before unknown from this region are constantly being discovered. J. N. Rose raised the number of known species of cacti from 12 to 30. A. S. Hitchcock studied the grasses which extend in great diversity from the lowlands to the snow line. W. Popenoe described about 100 species of fruits. Ferns are abundant and of many types ranging from the filmy ferns of the fog covered forests to the giant tree ferns of the tropical valleys. The genus *Eupatorium* occurs in many forms, more than 50 species being reported. Numerous species of the heath family are found in the forested mountains and the high *paramos*.

Among the more common economic plants are the *corozo* or ivory-nut palm (*Phytelephas macrocarpa*), which furnishes vegetable ivory for manufacturing buttons, the cacao tree (*Theobroma cacao*), from which the cacao bean is gathered, the hbre plant *Carludovica palmata* (not a palm), used for making Panama hats, the balsa (*g v*) tree or corkwood (*Ochroma lagopus*), furnishing the lightest timber in the world, and the cinchona tree which yields quinine. Wheat grows at elevations of from 4,500 ft to 9,800 ft and barley up to 11,500 feet. More than 100 kinds of useful woods have been described.

Mammals.—While in general mammals are comparatively scarce, according to G. H. H. Tate they are represented by a very wide range of species. In the forests east of the Andes the Primates are numerous, but on the west coast only three genera occur: spider monkeys, howlers and capuchins. The Carnivora include the jaguar, puma, ocelot, foxes, weasel, tayra, otter, skunk, grison, racoon, coati and kinkajou. The Ungulates comprise the tapir, two kinds of deer and two sorts of peccaries. Among the rodents are the amphibious capybara (east of the

Andes), paca, agouti and the rare *Dinomys*, the smaller forms include squirrels, rabbits, cavies and numerous rats and mice. There are numerous species of bats, including the bloodsucking vampire. Representatives of the sloths anteaters and armadillos are not rare. The opossums, with half a dozen genera, include the web footed *Chromectes*, and the curious little *Caeolestes*, the so called "living fossil," of the high Andes.

The chief governing factor in the distribution of these animals is the Andes mountains which run north and south through the country causing wide variations in the climate. Broadly speaking the climates are tropical from sea level up to 5,000 ft, subtropical from 5,000 to 11,000 ft, and temperate, from 11,000 ft up to snow line. These conditions, modified by rainfall, act directly upon the vegetation and the animal life within the several zones, resulting in the evolution of specially adapted forms. The only indigenous animals under domestication are the llama and alpaca. Neither is abundant. But horses, cattle, sheep, goats and pigs are now raised everywhere. In the high plateaus, sheep and cattle thrive particularly well.

Remains of extinct vertebrates, such as mastodons and horses, are found in the Pleistocene deposits of the highlands and also of the Pacific coast. The natives at the time of the arrival of Francisco Pizarro, in 1537, ascribed these to a race of giants which formerly inhabited the country.

Birds.—Frank Chapman stated that about 1,500 species of birds had been found in Ecuador. This is approximately one fourth of the South American avifauna and is doubtless a larger number of birds than has been recorded from any other area of similar size. Ecuador owes its exceptional abundance of bird life primarily to the extent and altitude of its mountains, which add to the lower or tropical zone, three additional zones, each of which has species that are restricted to it (endemic). They are the subtropical zone (alt. from 3,000 or 4,000 ft to 9,000 ft) with 237 species, the temperate zone (alt. 9,000 ft to 12,000 ft) with 142 species and the *paramo* zone (alt. 12,000 ft to snow line) with 33 species. These endemic zonal species have been derived from the tropical zone at the base of the Andes and also from both the south temperate and the north temperate zones. Their existence affords an admirable illustration of the stimulating effects of change of environment on the evolution of species. For example, Ecuador is known as the land of humming birds, but it is not generally realized that only 66 of its 147 species are found in the tropical zone, while 81 are confined to the upper life zones and in large part at least, have therefore been evolved since the latter part of the Tertiary when the mountains they occupy were elevated.

The brilliantly coloured tanagers (*Tanagridae*) are also commonly considered as characteristic of the American tropics, but of the 106 species found in Ecuador only 52 are known from the tropical zone, while 46 are confined to the subtropical and 18 to the temperate zone. Other birds with numerous species in Ecuador are the pigeons (*Columbidae*) 26 species, parrots (*Psittacidae*) 38 species, toucans (*Rhamphastidae*) 19 species, woodpeckers (*Picidae*) 37 species, antbirds (*Formicariidae*) 114 species, woodhewers (*Dendrocolaptidae*) 31 species, flycatchers (*Tyrannidae*) 160 species, and wrens (*Troglodytidae*) 32 species.

Sixty six species of birds that nest in North America visit Ecuador in winter. Among this number are the Carolina rail, or sora (*Porsana carolina*), blue-winged teal (*Querquedula discors*), kingbird (*Tyrannus tyrannus*), barn swallow (*Hirundo erythro gaster*), red eyed vireo (*Vireo olivaceus*), redbstart (*Setophaga ruticilla*), rose breasted grosbeak (*Zamelodia ludoviciana*) and scarlet tanager (*Pranga erythromelas*).

Fishes.—When compared with the Amazonian fauna, the fresh water fish fauna of the Pacific slope of Ecuador (see Carl H. Eigenmann, "Fishes of Northwestern South America," *Memoirs of the Carnegie Museum*, vol. 1, no. 1), is relatively meagre, only about 60 species being included. The fishes of the eastern part of Ecuador are as yet practically unknown. Although the species and many genera are now different, all of the fishes of the Pacific slope streams are similar in character to their Amazonian relatives and were evidently derived from, them before the uprising of the

Andes. This Pacific slope fauna is characterized by the lack of certain usual Amazonian types such as the electric eel and the piranha. One of the most remarkable of Ecuadorian fish is according to Arthur W. Henn of the Carnegie Museum is the rasbora (*Plecotomus spinosissimus*) which is a sort of pitted catfish so well protected by its spiny covering that, if care is taken not to frighten it it may be picked up by hand from the sundrills. In the same waters, the Guayas system, occurs a blind catfish the ciego (*Cetopsis occidentalis*), the eyes of which are covered with thick skin.

Another celebrated Andean species found in Ecuador is the so called volcano fish (*Astroblepus gualan*) which, by means of its disc-like sucking mouth and prickly fins is enabled to live in torrential mountain streams. Formerly this fish was erroneously said to be thrown in great quantities during eruptions from subterranean lakes within volcanoes.

Reptiles—All the major groups of reptiles are known. According to Alexander G. Ruthven there are fresh water and land turtles, crocodilians, lizards and snakes. Among the lizards, the beautiful fan lizards, Amazonian chameleons or Anoles, are conspicuous for their delicate changeable colours and flashing throat fans. Other interesting lizards are the *Ameiva*, active and conspicuous on bright warm days, the blind lizard *Amphibacna*, frequently found in ant and termite nests, the spiny *Elmhosauri*, and several geckos. The snakes of Ecuador vary in size from threadlike *Helminthophis*, which burrows in decaying wood, to the large boa (*Constrictor constrictor*). There are fresh water snakes, sea snakes, tree snakes, ground snakes and burrowing snakes. Many are harmless, but there are numerous venomous species. Among the latter are several opisthoglyph snakes, several protoglyph snakes, coral snakes (*Elaps* or *Micurus*) and the dangerous solenoglyph pit vipers, notably the *fer de lance* (*g u*). There are also various tree snakes such as *Oxybelis*, interesting for their attenuated form and habit of resembling vines. The crocodilians are represented by a true crocodile and the broad snouted cuman. A few fresh water turtles and the large land tortoise (*Testudo denticulata*) are known.

Insects—While the insect inhabitants of Ecuador embrace numerous genera and species representing the most important orders, no comprehensive survey has been completed. Campos enumerated about 1,550 known species, chiefly butterflies and moths (Lepidoptera), beetles (Coleoptera), grasshoppers and their allies (Orthoptera), and bees and ants (Hymenoptera). Of beetles alone there are estimated to be 3,000 species. In general it may be said that for each 1,500 ft. of elevation there is a new province of insect life. Lepidoptera have been collected on the slopes of Antisana at 16,000 ft. altitude. A giant beetle (*Dynastes hercules*) attains a length of five inches. Certain click beetles and fireflies are noted for their phosphorescent light. Among the Diptera is found or rather was found the mosquito *Aedes argenteus*, the carrier of the yellow fever germ, known also as *Sicogomyia fasciata*. Below 1,500 ft. elevation also occurs the mosquito *Anopheles albimanis*, carrier of the malaria germ. Numerous parasitic insect pests abound among the Indians.

HISTORY

Archaeology and Antiquities—All that is known about human life in Ecuador up to a few years before the arrival of the Incas, i. e., about two or three generations before the arrival of the Spaniards in 1537, is contained in archaeological and linguistic remains, for writing of any kind was not only unknown to the earliest inhabitants but even to the Incas themselves.

At various places in the western lowlands, in the central highlands and even in the forests east of the Andes are found archaeological remains, which prove the existence at certain times of a considerable culture. Although objects have been found which according to Max Uhle point to a relationship with the Maya civilization in Central America which was flourishing as early as A. D. 68 and probably much earlier, other objects indicate the presence of man in Ecuador several thousand years ago.

The pre-Inca archaeological remains of Ecuador are of three unrelated types of culture. One, peculiar to the high Andean

valleys a second, to the Pacific coast lowlands, and a third, to the forested region east of the Andes. The first two types prove, says Uhle, that two perhaps independent, migrations from Central America took place and that the emigrants were profoundly influenced afterward by a widely different environment. The region east of the Andes has furnished little archaeological material, but this shows a close affiliation with objects found in the great forest area along the upper Amazon, whose inhabitants Uhle believes migrated from Central America but turned eastward from the isthmus of Panama to follow the north coast through Colombia, Venezuela and the Guianas to the mouth of the Amazon, which they ascended. Perhaps at the same time there was a contemporaneous filtration of people south by way of the numerous waterways which drain into the Caribbean sea. The first type of remains, i. e., those peculiar to the high Andean valleys of Ecuador, may be subdivided into three minor classes in each of which the remains show a more or less centralized development. Remains of the first subdivision are found in the three northern provinces, Carchi, Imbabura and Pichincha. Those of the second class come from the region near the volcanoes, Tungurahua and Chimborazo, and those of the third subdivision from the provinces of Cañar, Azuay and Loja in southern Ecuador.

The most noteworthy features of the ceramic art of the first subdivision are long slender vessels found in large numbers, in the deep, well like tombs at Angel and vicinity, and bowls painted with many motifs of great interest in aboriginal decoration. The second subdivision is characterized by vessels with thin walls, or named with straight or wavy parallel lines. This is the most important of all the ancient culture centres of the Andes because of the stratified sequence revealed in excavations where six horizons have been recognized according to Uhle. The lowest of these, which is called the Proto-Panzaleo, no. 1 shows profound Central American influence, as Uhle has declared. The Proto-Panzaleo, no. 2, which overlies the first, is a continuation of the first but with marked traces of a new influence from the north. The Tuncabuan overlying this is thinner and therefore indicates a period of shorter duration than the others, but it is more widely spread, being found over almost the entire Andean region of Ecuador. It is marked by the disappearance of tripod vessels, by abundance of negative painting, and by the first white pottery ornamentation. There also appear objects of copper. The next, or San Sebastian, layer contains new types of pottery vessels, and there progress was made in architecture, as shown by the ruins near Guano. In the fifth horizon from the bottom the art of Chimborazo reached its highest development. Negative and positive painting of earthenware flourished, and jars with conventional human faces and arms, placed in low relief on the necks and upper body parts of the vessels are characteristic. In this restricted region there is much pottery of this style, but none has been discovered beyond. Human bones and innumerable small shell beads have been found in some vessels, while in others yellow powder reveals Chicha sediment showing that they had been filled with liquid for the refreshment of the deceased with whom the receptacles had been buried. Many copper ornaments are in this horizon. This is the art of the Puruha who lived as late as the time of the Spanish conquest. The sixth horizon, i. e., the most recent, is called the Huavalac and is characterized by "lost colour" ware.

CENTRAL AMERICAN INFLUENCE

Near Cañar, Azuay and Loja, a high degree of culture is revealed, of marked Central American influence, says Uhle. There architecture reached a high plane as the ruins of splendid fortresses and other edifices attest. A wealth of gold ornaments and implements has been found in tombs at Chorodeleg and Sigis. In the second great cultural area, viz., that of the Pacific coast, climatic conditions were very different from those in the highlands, for the region is comparatively low and almost entirely covered with forests. This zone contains two cultural centres, one extending from what is now Esmeraldas south 150 mi., and the other in the province of Manabí with its alternate arid and humid climatic conditions. These two cultures, says Marshall Howard Saville, prove

the existence of two distinct peoples whose occupancy extended over a considerable period, and whose highest development seemingly was reached long before the coming of the Spaniards. Their cultures differ widely from those represented by the artifacts of the highlands, and apparently there was no connection between the two.

In some respects the most interesting culture in Ecuador is that of Esmeraldas. Prominent features are the surprising advancement it shows in modelling clay figures and the great progress in gold working. A dominant feature is the almost microscopic character of many of the objects fashioned in filigree, another is the occurrence of jewels of pure platinum or of platinum and gold filigree. Many pieces are so closely allied to Mayan artifacts as to be almost indistinguishable. The type of culture in general is intermediate between the Mayan and that of the Peruvian coast.

Of the Manabí culture, the outstanding feature is the development of stone architecture, almost entirely unknown in the interior highlands and entirely on the Esmeraldas coast. The Manabí sculptures are unique in South America, says Saville, and have been found in the ruins of houses in hilltop villages and in a few town sites on the arid plains of Manabí. These sculptures include stone seats, believed to have been used ceremonially in household sanctuaries, sculptured slabs of stone, or bas reliefs, representing female deities, etc., columns recalling those of Costa Rica, birds, animals and human figures in stone. A few pieces of copper and some ornaments of gilded copper are the only examples that have been discovered thus far of the metal work of the ancients of Manabí. In their towns the dead were buried in bottle-shaped tombs cut into the solid rock as well as in mounds or "tolas."

The third great zone of culture east of the Andes has not been studied. It is represented by a few remains in the Napo region which distinguish it from that of the neighbouring highlands and the Pacific coast, it is apparently related to one farther east near the mouth of the Amazon.

Writing was unknown before the Spanish conquest. At the time of the arrival of the Incas in Ecuador, a number of languages were spoken. Several of these survived the superposition of the Inca language, i.e., the Quechua, to the time of the arrival of the Spaniards. One, the Esmeraldas, has died out only in recent years, while two, the Cayapa Colorados and the Jivaro still survive owing to their existence in inaccessible regions. On the basis of geographic names as well as the vocabularies of the three known pre-Inca languages above mentioned, the following languages are recognized as having been in existence at or shortly before the arrival of the Incas.

Quillacingas, Pastos, Caranquis (or Imbaburas or Cayapa-Colorados), Tacungas or Panzaleos, Purihaes, Cafitris, Paltas and Jivaros, Bolona (Rabona and others), Esmeraldas, Manabitas or Mantenos and Mochica (or Yungas).

Jacinto Jijón y Caamaño thinks that the oldest types represented in Ecuador were the Cayapa Colorados, the Jivaros and the Chimus and that the others represent modern elements in Ecuadorian ethnology. For Inca history see INCA.

SPANISH CONQUEST

Spaniards' Arrival.—In 1526 Bartolomé Ruiz, the pilot of Francisco Pizarro, having been sent south from the main base of the second expedition for the conquest of Peru, at that time situated at the mouth of the San Juan in what is now Colombia, rounded Cape Pasado to 1° S and returned. He was thus the first European to cross the equator on the Pacific coast of South America, and to see the shores of what is now Ecuador. Ruiz first reached the Esmeraldas where the present town of Esmeraldas is situated and discovered there three large settlements of Indians who received him in a very friendly manner. They wore jewels of gold and three of the Indians who came out in canoes to receive Ruiz wore golden diadems on their heads.

Ruiz on his return to the San Juan informed Pizarro of his discoveries, and then, joined by Pizarro and Diego de Almagro, made a second voyage as far south as Atacames, discovering more large towns, much cultivated ground and a formidable array of

well armed Indians. Returning to the island of Gallo in 1° 57' N they sought reinforcements. Early in 1527 Pizarro sailed to the Gulf of Guayaquil opposite the town of Tumbes where they saw the undoubted signs of a great civilization, confirmed by a cruise as far south as Santa (9° S). Pizarro returned to Spain where, by the contract between himself and the crown, dated July 26, 1529, he was appointed captain general and *adelantado* of the region. He returned, this time with a large retinue, among them his four brothers, his young cousin Pedro Pizarro the future historian, and several Dominican priests. He sailed from Panama on Dec. 28, 1531, with three small vessels carrying 183 men and 37 horses, and in 13 days arrived at the Bay of San Mateo, in northern Ecuador, where he landed his forces and commenced a devastating march along the entire western coast to the Gulf of Guayaquil. He crossed this in boats to Puní, where a destructive war was waged with the unfortunate natives. After subjugating them Pizarro crossed over on ships to the mainland where now is situated the town of Tumbes. Pizarro and his forces left Tumbes on May 18, 1532, founded the city of San Miguel, marched on ward in search of the Inca Atahualpa, made him prisoner and massacred his forces. Atahualpa was executed in the square of Caxamarca on Aug. 29, 1533, and the Inca empire came to an end.

Pizarro, desirous of forbidding the entrance of adventurers into Peru to make discoveries on their own account, sent Sebastián de Benalcázar as his representative to govern San Miguel which was at that time the key to Peru. In Nov. 1533 Benalcázar learned that Pedro de Alvarado, one of the conquerors of Mexico, had sailed from Guatemala to take the kingdom of Quito, which was famous for the riches of Atahualpa. Benalcázar collected a few Spaniards and Indians, marched from San Miguel in the last days of 1533 and crossed the cordillera of the Andes to the great highway of the Incas in the province of Loja, now Ecuador, at that time inhabited by peaceful tribes of Palcas. Following this north without opposition, he reached the pueblo of Tomebamba in the country of the Cañaris and persuaded these tribes to join forces with him against their enemies to the north. He then marched north through the province of Azuay, defeated the Indians at Riobamba and finally in May or June 1534 arrived at the city of Quito which he found in ruins. He then continued north to Cayambe where he received word that Almagro had been sent by Pizarro to join forces with him in opposing the expedition of Pedro de Alvarado, which had landed at Puerto Viejo in March 1534 and which was proceeding with frightful hardships straight east from the coast through unknown forests to ascend the west slope of the Andes where no trails even existed. Returning to Riobamba, Benalcázar met Almagro and they founded the city of Santiago de Quito on Aug. 15, 1534, as an evidence of formal possession of the territory by Pizarro. This then was the first city to be founded in Ecuador. Alvarado when he finally reached the summit of the Andes, after one of the most extraordinary expeditions of the Spanish conquest, found that he had been outmatched. On Aug. 26, 1534, Alvarado agreed to retire from Peru.

Pizarro then proceeded to pacify Ecuador. The city of Santiago de Quito, founded near the present site of Riobamba, was moved to the present site of Quito, on Aug. 28, 1534, and the name changed to San Francisco de Quito. The territory embracing the most northern limits of the Inca empire was soon conquered and finally the conquest continued north into what is now Colombia. It was then continued east of the Andes. Lured by the account of fabulous riches, Francisco Pizarro appointed his brother Gonzalo governor of Quito on Dec. 1, 1540, and the final conquest of Ecuador took place. Leaving Quito in Feb. 1541, Gonzalo Pizarro crossed the Guamaní pass of the Andes, 13,350 ft. above the sea, wandered in the forests east of the Andes many months and finally, after a feat of exploration which brought him to the Amazon and permitted Francisco de Orellana, one of his lieutenants, to descend it to its mouth, returned to Quito in rags and with but 97 men, leaving his companions in unmarked graves in the forests east of the Andes.

Conquerors' Discords.—The period of conquest was followed by civil war among the *conquistadores*. Diego de Almagro and Francisco Pizarro perished by assassination and Gonzalo Pizarro

rebelled against Spain. All the new possessions in South America were now erected by the crown into the viceroyalty of Peru and in this governmental body was concentrated the executive power. To this was added a judicial body, the *audiencia*, and the first viceroy was the president of the first *audiencia* of Lima. In addition Roman Catholicism, the state religion, was put in charge of a bishop, the first bishopric embraced practically all the viceroyalty. The first viceroy, Blasco Núñez Vela, arrived in Ecuador en route to Peru but was defeated by Gonzalo Pizarro at the battle of Inaquito, near Quito, Jan. 18, 1546. He himself was killed and his head exhibited at Quito. Gonzalo Pizarro, however, did not long enjoy the fruit of his rebellion for a new royal representative, Pedro de la Cueva, met and defeated him at Jaqui-jiguaní, Peru, on April 9, 1549. Surrendering, he was executed almost forthwith.

The government by viceroys continued for 174 years. For the first few years after the establishment of the viceroyalty of Peru the territory now known as Ecuador was ruled by its representatives in the cities of Quito, Guayaquil, Puerto Viejo, Loja, and Cuenca. In 1545, the bishopric of Quito was formed of that portion of the bishopric of Cuzco extending from Payta north into what is now Colombia, and on Aug. 29, 1563, the *audiencia* of Quito was established with judicial authority over the region from Carchi on the north to Buenaventura on the Pacific, and to far east of the Andes, covering all the explorations of Gonzalo Pizarro in 1541, south as far as the latitude of Payta, thus embracing the bishoprics of Quito and Popayan. Because of the isolation of the region from viceregal authority and the presence of the governor as president of the *audiencia*, that body came to be not only judicial in nature but administrative as well.

The *audiencia* or presidency, of Quito, as it was almost interchangeably called, remained a part of the viceroyalty of Peru until, by royal edict of Mar. 27, 1717, it was transferred to the newly created viceroyalty of Nueva Granada, whose seat was at Bogotá. Six years later, the new viceroyalty was abolished and Quito returned to the authority of the viceroy of Peru but in 1740, when the viceroyalty of Nueva Granada was restored, Quito was again put under its jurisdiction, where it remained until the end of Spanish dominion.

Independence.—The ultimate phase of colonial history, viz., the movement for independence, had its birth in the activities of Eugenio Espejo (born in Quito, 1747), Antonio Ante, Juan Pío Montufar and others. The first blow was struck in Quito on Aug. 10, 1809, but the new revolutionary government established soon perished and on Aug. 2, 1810, most of the leaders responsible for it were massacred in Quito. A second attempt on Oct. 11, 1810, set up the "Eight Provinces of the State of Quito" which fell in Dec. 1812. The royalists then maintained their power until May 24, 1822, when, with the assistance of Antonio José de Sucre sent by Simon Bolivar, the republican forces defeated the royalists at the battle of Pichincha and two days later Aymerich, the last president of the *audiencia*, capitulated. Ecuador, under the name of "department of the south," now joined with Venezuela and Colombia in the confederacy known as the republic of Colombia.

RULE OF THE PRESIDENTS

The efforts of Bolivar to maintain this greater republic were unsuccessful. Although Bolivar defeated Peru in 1829, fixing the limits between Peru and Colombia as those of the old viceroyalties of Lima and Bogotá, Venezuela soon after withdrew from the confederacy (Nov. 29, 1829), and a constitutional convention in Riohacha (Aug. 11 to Sept. 28, 1830) the three dependent units of Azuay, Guayas and Quito formed themselves into an independent state called the Estado del Ecuador in Colombia and adopted the first constitution of what is now Ecuador.

The history of Ecuador since its separation from Bolivar's great state has been very largely that of its great dictators, of whom three stand out most prominently: Juan José Flores, Gabriel García Moreno and Eloy Alfaro. Its course has been controlled by internal struggles of Liberals against Conservatives of section against section, and, particularly in the 20th century, by economic factors.

The first president of the new republic was Gen. Juan José Flores, a Venezuelan by birth, who had identified himself with Ecuador and had led the movement for separation. President Flores represented a Conservative group, whose stronghold was inland Quito, conservative, aristocratic, and devoutly loyal to the Roman Catholic Church, in politics as well as in religion. There were, however, particularly in Guayaquil, elements in whom the liberal ideas of the 18th century ran strong. Coupled with this was sectional rivalry between Guayaquil and Quito.

By 1833, opposition to Flores, headed by Vicente Rocafuerte, became formidable, and soon revolt broke out. After over a year of indecisive civil war, the two rival leaders effected a compromise whereby Flores agreed to acquiesce in Rocafuerte's election as his successor in 1835. Four years later (1839) Flores returned as president, but soon had difficulties with congress, and after further disorders accepted exile in 1845, going to Spain, where he involved himself in plans for restoration of Spanish control. In 1851 he made an unsuccessful attempt to return to power.

Meanwhile president had followed president, with only the exceptional one serving his full term. In Jan. 1860, while Ecuador was torn by internal dissensions, Peruvian warships blockaded Guayaquil and forced acceptance of a treaty recognizing Peru's boundary claims. This treaty was repudiated shortly, however, when the government signing was overthrown in Sept. 1860 by a revolution headed by Gabriel García Moreno, son in law of Flores, and one of the most distinctive figures in Ecuadorian history.

Gabriel García Moreno (1821-1875), whose length of service amounted to 10 years and nearly 5 months (two terms), held power longer than any other president. He was starting a third term when he was assassinated on Aug. 5, 1875, thus having the second distinction of being the only president to die by assassination while in office. His period of power brought the church party to its zenith in Ecuador, so much so that García Moreno's presidency was often referred to as a Jesuit government. He perhaps did more for Ecuador than any other president, for he gave it a strong government and peace. He caused the Roman Catholic Church to send out from Europe a number of Jesuit priests, eminent in science, to become teachers. Among these were Theodor Wolf, the geologist, Sodiro, the botanist, Menten, the astronomer, Dressel, the chemist and Kolberg, mathematician. He was a great patron of science, a man of extraordinary energy and a strict ruler. The reaction from his policy carried successive governments to greater and greater "liberalism" and finally to the deprivation of the Catholic clergy of their extensive landed properties, to the establishment of civil marriage and to freedom of worship.

The years following García Moreno's death were marked, initially, by a reaction against the extreme clericalism of his time, but not for long. The issue of separation of church and state continued to be bitterly fought, amid nearly constant internal disturbance. Not until the rise to power of Eloy Alfaro in 1895 did order and relative stability return to Ecuador. During his presidency (1895-1901) various restrictions upon clerical activity were enacted into law, comparable in most respects to those exercised by Spain during the colonial regime. His successor, Leónidas Plaza Gutiérrez, went further, and under him civil marriage and divorce were legalized and control of education taken from the hands of the church.

In 1906, former President Alfaro returned to power, and was elected president for a second constitutional term. Under him a new constitution was promulgated. It made the government more centralized, forbade immediate re-election of a president, and set forth various liberal reforms. This constitution, the country's 12th in 86 years, lasted for 2 years, longer than had any of its predecessors. Under Alfaro, too, the railway from Guayaquil to Quito, first in the country, was completed (1902). In 1911, during a revolution against Alfaro's successor, the former president was arrested, and a few months later was dragged from his prison and murdered by a mob in Jan. 1912.

At the outbreak of World War I, Ecuador proclaimed its neutrality, but after entrance of the United States into the conflict, relations with Germany were broken off and German shipping in Ecuadorian harbors seized.

A coup d'état in 1925 ushered in a period of excessive political instability which was not terminated until the election of Pres. Galo Plaza Lasso in 1948. The coup of 1925 brought into power a junta which dissolved congress. Subsequently a military board assumed control and made Isidro Ayora president. In 1929 constitutional reforms were resumed and Ayora's authority was confirmed by election. His administration, however, lost its army support by its budgetary policy and in 1931 Ayora resigned. Factional strife and minor uprisings, partly the results of economic depression, prevailed thereafter. In Aug. 1935, Pres. José María Velasco Ibarra was deposed by the army, and a junta was set up with Federico Páez as nominal head. The government sternly repressed adverse criticism, but, as internal unrest continued, Páez was forced to resign (Oct. 24, 1937), being succeeded by his war minister, Gen. Alberto Enriquez Gallo. Enriquez Gallo served until a constituent assembly, meeting Aug. 10, 1938, chose Manuel Marín Borrero and subsequently (Dec. 1) Alberto Mosquera Narváez.

Narvaez, fourth president in 14 months, was able to retain his position only by force, crushing a revolution with artillery after two days' fighting, and died in office Nov. 17, 1939. His successor, Carlos Alberto Arroyo del Río, resigned in favour of Andrés F. Córdova (Dec. 11) to run in the Jan. 1940 presidential elections. Elected, he took office Sept. 1940.

On May 28, 1944, Pres. Arroyo del Río was overthrown in one of Ecuador's most violent revolutions. The insurgents delivered the government to former President Velasco Ibarra, who remained in office until Aug. 23, 1947. His ouster at that time inaugurated a month of chaotic instability characterized by frequently changing administrations. Pres. Carlos Manchengo, who had deposed Velasco Ibarra, was himself overthrown on Sept. 2, 1947, and his successor, Pres. Mariano Suárez Veintimilla, presented his own resignation, effective Sept. 17, 1947, to congress. That body thereupon chose Carlos Julo Arosemena to serve out the unexpired portion of Velasco Ibarra's term. Arosemena was successful in achieving sufficiently orderly conditions to permit a relatively free presidential election to be held on June 6, 1948. Galo Plaza Lasso, the victor in that electoral contest, embarked on Sept. 1, 1948, on a four-year presidential term.

(J H SR, L W BE, G I B)

POPULATION, GOVERNMENT, ETC

Population.—The first national population census ever conducted in Ecuador was taken in conjunction with the over all 1950 census of the Americas. Figures published at that time set the population of Ecuador at 3,076,933. Indians accounted for about 60% of this figure, mestizos 25% to 30%, and whites at most 15%. There are a few Negroes on the coast. Guayas is the most populous province, with Pichincha, Manabí, Azuay, Loja and Chimborazo following in order. The language of the whites and mestizos is Spanish, that of most of the Indians is Quechua, although some speak Spanish in the forest region to the east of the Andes. The Jivaro language is spoken among many of the Indians.

Some attempts to attract European immigration were made, but with little success. During World War II, war refugees were invited to settle in the country, and, throughout the Hitlerian era, about 1,000 Europeans, many of them Jews, came to Ecuador as immigrants. All in all, however, there was probably a smaller proportion of new blood brought into Ecuador after independence than into any other country of South America.

Government.—Under the constitution of Dec. 31, 1945—the republic's 15th constitution—Ecuador was declared a unitary or cen-

Army, Navy and Aviation.—At mid-20th century the army consisted of approximately 70,000 with 40,000 reserves. Military service was compulsory for men on reaching the age of 18. Lots were drawn to determine who was to undergo special training at that time. All men from 18 to 50 years of age are part of the reserves. The Ecuadorian government maintained at the aviation base at Guayaquil a school of aviation where young Ecuadorians were trained as pilots and in the mechanics of ground air service. It was there that numbers of men became proficient in the various branches of air service. The navy maintained a naval school at Salinas.

Religion.—Of the pre-Inca religions the only one remaining is possibly that of the Jivaro Indians of eastern Ecuador, which Rafael Karsten says is wholly unaffected by Christianity. In this there is no notion whatsoever of a supreme being and creator of the universe, but it is by no means a pure demology. The Inca religion has apparently entirely disappeared (see INCA).

The Spaniards made the conquest of Peru not only a territorial extension of their power but a means of conversion of the aborigines to the Roman Catholic religion. The capitulation of July 26, 1529, made Hernando de Luque bishop of Peru, and Francisco Pizarro, when he returned from Spain after having made this contract, took with him a number of Dominican priests, among them, Fray Vicente de Valverde. Soon more priests, this time Mercedarians, arrived and the campaign to convert the Indians was well started. Luque never went to Tumbez to take over his charge, but Valverde was made bishop at Cuzco over all of Peru. González Suárez states that by the end of the 17th century there were in Ecuador alone 42 convents belonging to the Dominicans, Franciscans, Augustinians, Mercedarians, Jesuits and barefooted Carmelites. The number of priests was very large, Quito alone having, as he states, about 1,200 priests. Great wealth was accumulated and "great damage was caused to the moral advancement of the people by the bad example not only in lack of virtue among the priests, but by their lack of good manners." González Suárez concludes, however, that the convents were the cradle of culture. It is certain that by the end of the 17th century, no part of the Andean region remained unsvisited by the missionaries. In 1767 the Jesuits were expelled from all the Spanish dominions in America.

The opposition to the official religion was intended to restrict clerical influence in political affairs. The growth of liberalism resulted in 1889 in the church tithes (10% of the value of the production of the farms) being abolished, a tax of 3 per mil on the value of the farms was substituted. In 1902 civil marriage was permitted and in 1904 the church was placed under state control, the foundation of new religious orders was forbidden and new religious communities were denied entrance. In addition all members of the episcopate had to be Ecuadorians. The state took over the landed property of the religious orders and administered it under a board of charities which gave a pension to the friars. The excuse for this latter action was stated to be the great wealth of the church, gained largely through participation in legacies and by labour which received no earthly pay.

A few Protestant missionaries penetrated the country, among the Indians east of the Andes (Tena and Macas). Freedom of religion, provided for in the constitutions of 1906 and 1929, was limited by the 1945 constitution.

The Catholic Church has an archbishop at Quito and bishops in Ibarra, Robamba, Cuenca, Guayaquil and Puerto Viejo.

Education.—The ministry of public instruction exercises supervision over all educational institutions. Higher education is provided at the Central university of Quito, the University of Cuenca, the University of Guayaquil, and the Junta Universitaria of Loja, all of them government supported. The Central university has faculties of law and social sciences, physical and natural sciences, philosophy and letters, and medicine. The national veterinary school, a school for nurses and a vaccination institute come under the last, a school of agronomy under the faculty of physical and natural sciences, and a section of pedagogy under that of philosophy and letters. The University of Cuenca has faculties of medicine and of law and political and social science, along with a school of painting and art and the superior school of mining engineering. Faculties of law and social science, medicine, pharmacy, odontology, physical sciences and mathematics and a school for nurses are part of the University of Guayaquil. The Junta Universitaria has only a faculty of law and political and social sciences. Teacher training is provided in four normal schools, two in Quito and one each in Cuenca and Guayaquil. In addition, short elementary normal courses have been established in seven cities.

A committee consisting of experts in educational methods, school architecture, public health, etc., known as the National Council on Education, was appointed by the government in 1935 to reorganize primary and secondary education along modern lines, by issuing pamphlets to interpret the ideals of the new type of school, by building experimental schools, organizing demonstration schools for Indians and establishing welfare centres for underprivileged children of preschool age.

At mid-20th century there were about 3,500 public and private elementary schools with about 265,000 pupils, and 135 secondary schools with enrolment of 18,000. To provide necessary funds for education the government required municipal governments to increase their contributions toward defrayment of school costs. Revolutionary changes in secondary school requirements were made, with radical changes in the curriculums which broke down the rigidity of the old system and its

of 64 members elected for two-year terms theoretically on the basis

chalet

There are 17 provinces, 86 cantons and 651 parishes. Each province is ruled by a governor, each canton by a *jefe político*, and each parish by a *teniente político*. The Galápagos Islands are administered through the ministry of national defense and are, technically, a naval command. The Oriente is divided into the two provinces of Napo-Pastaza and Santiago-Zamora.

excessive expenditures and through enlargement of the number of elective courses made for flexibility. Further efforts at school improvement were made by introducing teachers to improve themselves. In 1914 a campaign against illiteracy was launched, the government attempted to impose a fine upon landowners for each illiterate person over 12 years old working on the property.

Despite these efforts, however, illiteracy was still estimated at 60% in 1945.

In addition to the National library at Quito are municipal libraries at Quito, Guayaquil and Riobamba.

TRANSPORTATION AND FINANCE

Transportation—Guayaquil, situated on the Guayas river about 40 mi from the coast, is the chief port. Almost all of the country's foreign commerce flows through it. The Guayas is navigable for 40 mi above Guayaquil. Several other small rivers are navigable as is the Marañon (the upper Amazon) in the eastern part of the country.

Railways—Approximately 700 mi of railway was in operation at mid century, the most important being the Guayaquil and Quito rail way, 297 mi in length connecting the capital with the coast. Its construction completed in 1908, was regarded as having been one of the most difficult ever attempted. Its cost was in excess of \$19,000,000, averaging \$68.15 per mile. Originally a private enterprise, it was subsequently nationalized, as was all other railway trucking in the country.

Highways—New highway construction and rehabilitation of old roads was pushed extensively in the first half of the 20th century. In the single year 1916, the automobile highway mileage increased from 2.48 mi to 2,710 mi or 12%. Highway mileage at mid-century was approaching 3,000 mi, including the Ecuadorian section of the Pan American highway.

Aviation—Ecuador has external communication by air with all parts of the Americas, to the north through Colombia, and to the south through Peru. Aviation facilities were materially improved when Quito became a regular port of call for north south airlines.

Revenues—The ordinary budget for 1952 was estimated to balance at 465,000,000 sucres, the equivalent of \$30,600,000 U.S. Decline of the sucre in international exchange was partially responsible for the increase in terms of sucres.

In the average fiscal year, revenues are apportioned among the following sources: taxes on state monopolies, 25%; import duties, 24%; consular fees, 6%; petroleum taxes 5% substitute for sales tax, 5%; income tax, 5%; port duties, 4%; post office, 4% stamp tax, 3%; rural property tax, 3%; public debt, 5%; foreign affairs, 5%; miscellaneous, 25%. This pattern was expected to change in consequence of a new individual income tax adopted in 1952. Expenditures normally reflect the following proportions: national defense, 22%; public works and communications, 15%; education, 15%; treasury, 9%; military, 9%; social welfare, 2%; public debt, 5%; foreign affairs, 5%; general expense, 4%; state pensions 4%; judiciary, 2%; others, 5%.

The public debt of Ecuador (foreign) was \$41,341,000 on Nov. 1, 1950, the internal debt totalled 121,548,000 sucres on that date.

Currency Exchange—Ecuador was on a gold standard, adopted in 1908, until 1912, when payments in gold were stopped by decree. Although the bank-note circulation increased to a considerable extent after 1914, the exchange rate was maintained with very little fluctuations at about the legal parity of \$0.4867 to the sucre, until in the middle of 1918 it declined in value to 35 cents U.S. This situation was due to the effects of World War I and to the passage of the "law of the inconvertibility of bank notes" which was really a moratorium. This law probably saved the banks, particularly the Banco Comercial y Agrícola de Guayaquil, as it absolved them from paying gold for their notes, but certainly did great injury to the country at large. In Nov. 1918, the sucre suddenly rose in value to 15 cents and held this to the beginning of 1920 when it was quoted at 47½ cents. The exchange market then broke suddenly and the sucre depreciated in value until it reached 183 cents, when, by executive decree of Nov. 16, 1922, the government took over the monopoly and complete control of all foreign bills of exchange, fixing the rate of exchange at about 47 cents. This official rate was subsequently reduced to approximately 33 cents and eventually to 25 cents, remaining at the latter level until official control was abolished in Oct. 1924.

Meanwhile, in the open market, the sucre had fallen as low as 17 cents, following abolition, however, it rose as high as 25½ cents before beginning a decline which carried it as low as 6 cents in 1952.

Production and Commerce—Ecuador's chief product is cacao, in which it is third in world production. Cacao was exported to Europe as early as the 16th century, and until the 20th century Ecuador was the world's leading producer. By the second decade of the 20th century, however, it had been exceeded by Brazil and subsequently by the Gold Coast of Africa as well. This relative decline was due not only to increased production elsewhere, but to local difficulties as well, especially to the ravages of the famous witchbroom disease and of the monilia disease. By 1936 production had fallen from a former high of 16% of world output to 2%. Nevertheless, in 1950 cacao accounted for 29% of the country's exports, and the country's prospects still depended primarily on this product.

Coffee ordinarily ranks fifth to first among exports of the country, accounting in 1950 for 20% of all exports. Bananas were first ex-

ported in 1931, and comprised 15% of the total exports in 1950. A government decree of July 8, 1938, restricted the holdings of a single foreign company to 50,000 ha, and required the sale of any excess to Ecuadorian citizens within five years.

Another industry of Ecuador is the production of tagua, or vegetable ivory, a palm fruit whose fruit is used as a substitute for elephant tusk product. The tagua, or Panama hat, so called because exports enter world trade through Panama, is made from the straw of a native plant (*Carludovicia palmata*).

Mineral Production—Gold production was stimulated by the decline of the sucre, but remained small. In 1949 it aggregated 99,741 troy ounces.

Development of petroleum resources began in 1925. In that year 144,000 bbl of crude petroleum were produced, and the output steadily increased until it was between 2,000,000 bbl and 3,000,000 bbl annually (2,617,000 bbl in 1949). Around 95% of the production is in the hands of one British company.

Foreign Commerce—Quoted in either Ecuadorian sucres or United States dollars, Ecuador's foreign commerce increased rapidly after World War II, but in part this reflected both the fall of the sucre and inflation in the United States.

Ecuadorian export and import figures for 1936, 1939 and 1951 were as follows:

	1936 (U.S. \$)	1939 (U.S. \$)	1951 (U.S. \$)
Exports	13,493,000	11,341,000	61,000,000
Imports	10,857,000	10,173,000	47,000,000

The United States has long been both the largest buyer of Ecuador's exports and the principal supplier of her imports. U.S. Ecuadorian commerce, expressed in terms of the major commodities traded, was as follows at mid century:

Chief exports to U.S.	First 9 months of 1951 (U.S. \$)	Per cent increase over same period 1950	Chief imports from U.S.	First 9 months of 1951 (U.S. \$)	Per cent increase over same period 1950
Cacao	9,500,000	12	Automotive parts	4,800,000	60
Bananas	9,200,000	31	Grains and preparations	2,600,000	44
Coffee	5,600,000	34	Textile manufactures	2,100,000	35
Panama hats	2,700,000	4	Furniture	1,800,000	25
			Electrical machinery	1,300,000	20

ECZEMA, a common and important inflammation of the skin originating without visible external irritation, and characterized in some stage of its evolution by a serous exudation. For an attack of eczema two conditions are necessary, a predisposition or special irritability of the skin, and a directly exciting cause. The first condition is usually inherited or depends on some underlying constitutional state. The number of such states incalculable and their diversity are expressions of our ignorance of the real causation, but there is an undoubted relationship between eczema and certain forms of functional neurosis, particularly asthma. Sufferers from rheumatism and gout are also prone to eczema, though the exact relationship is much disputed. Eczema is not contagious, though when complicated by pyogenic micro organisms (impetigo), it is both auto-inoculable and contagious. Females (except when menstruation is becoming established, and at the menopause) are less liable to be attacked than males. In old age the sex influence is lost.

An attack of eczema is usually described as acute or chronic, but the only distinction lies in its greater or less intensity at the time of description, it has nothing to do with the length of time that the disease has lasted. It usually begins with local itching and burning and an erythematous blush, on which numerous tiny vesicles form. The vesicles grow larger, run together, and either burst or are broken by the patient's scratching, a clear fluid exuding which stiffens linen. The discharge does not dry up at once, but continues to exude—hence the name of "weeping eczema" when this is a prominent symptom. In some cases papules predominate, in others, especially when the face is attacked, erythema is more marked. The general health seldom suffers appreciably, unless the itching is so bad as to make sleep impossible. The irritation and local heat may be out of all proportion to visible changes in the skin, and in neurotic patients the nervous excitement may be extreme. The attack may affect any part of the body, but it usually begins at one of the following sites: the bends of the elbows or knees, the groins, between the buttocks, the groove behind the ears, the scalp, the palms or the soles, and the breasts of women. According to its position the form of the eczema is somewhat modified. On the front of the legs and arms, there is uniform redness. On the scalp it is generally seborrhoeic, and in children, especially when pediculi are present, it will become pustular. On the palms and soles it brings about thickening of the epidermis and the formation of cracks.

Treatment is unsatisfactory. Some cases are benefited by X-rays, others by alkaline bicarbonates or calomel, but the condition seems to wax and wane, or even disappear in an arbitrary way and the last treatment employed is given the credit. The only safe statements are (a) that the inflamed area should be protected from air and irritation and (b) that highly seasoned foods should be avoided.

EDAM, a town in the province of North Holland, close to the Zuider Zee, about 13 m NNE of Amsterdam. It is connected with the Zuider Zee by a fine canal protected by a large sea-lock (1828). Pop. (1940) 8,947. Germany occupied Edam in 1940.

Edam took its name and origin from the dam built on the Ye, which joined the Purmer lake close by. Free access to the Zuider Zee was obtained by the construction of a new dock in 1357, when the town also received civic rights from William V of Bavaria, count of Holland. Owing to the danger of the extension of the Purmer and Beemster lakes, Philip II of Spain caused a sluice

to be built into the dock in 1567. In the next century Edam was a great shipbuilding centre, and nearly the whole of de Ruyter's fleet was built here, then the harbour began to get silted up, and commercial and industrial activity slowly waned. The Great Church (St Nicholas) probably 14th century, was largely rebuilt after a fire in 1602, which destroyed nearly the whole town. It contains some fine stained glass and carved woodwork of this period. The Little Church (15th century) was demolished in 1883, except for a portion of the nave and the old tower and steeple. The town hall dates from 1737, and there is a museum founded in 1895. Cheese making is important and Edam gives its name to the "sweet milk cheese" (*zoetemelks kaas*) made throughout North Holland.

EDDA, the title given to two very remarkable collections of old Icelandic literature. Of these one bears that title from the middle ages, the other is called *Edda* by a comparatively modern misnomer. The word is first met with in *Rígsþula*, a fragmentary poem dating from the first half of the 10th century, where it is introduced as the name or title of a great-grandmother. From the 14th to the 17th century, this word—but no one has formed a reasonable conjecture why—was used as a synonym for the technical laws of the Norwegian Court-metre, *Eddu regla*, and "never to have heard or seen Edda" signified "never to have learned the art of poetry." The only known work by the name in the middle ages was the miscellaneous group of writings composed by Snorri Sturluson (q.v., 1179-1241), the greatest name in old Scandinavian literature. It is believed that the *Edda*, as he left it, was completed about 1222. Whether he gave this name to the work is doubtful, the title first occurs in the *Uppsala Codex*, transcribed about 50 years after his death. The collection of Snorri is now known as the *Prose* or *Younger Edda*, the title of *Elder Edda* being given to a collection of mythological and heroic poems, discovered by the Icelandic bishop of Skálholt, Brynjólfur Sveinsson, in 1643 and erroneously named by him the *Edda* of Saemundr.

The Prose Edda—Properly known as *Edda Snorra Sturlusonar*, this was undoubtedly written by Snorri Sturluson. It is divided into five parts, the Preface or *Formdli*, *Gylfaginning*, *Brágarœður*, *Skáldskaparmál* and *Háttatal*. The Preface bears a very modern character and simply gives a résumé of the biblical story of the creation and the flood, with a brief account of the rise and spread of paganism. *Gylfaginning*, or the Delusion of Gylfi, on the other hand, is the most precious compendium which we possess of the mythological system of the ancient inhabitants of Scandinavia. The *Brágarœður*, or sayings of Bragi, are further legends of the deities, attributed to Bragi, the god of poetry. The *Skáldskaparmál*, or Art of Poetry, commonly called *Skálda*, contains the instructions given by Bragi to Agnir, and consists of the rules and theories of ancient verse, exemplified in copious extracts from Eyvindr Skáldaspillir and other eminent Icelandic poets. The fifth section of the *Edda*, the *Háttatal*, or Number of Metres, is a running technical commentary on the text of Snorri's three poems written in honour of Hákon, king of Norway. Affixed to some mass of the *Younger Edda* are a list of poets and a number of philological treatises and grammatical studies. These belong, however, to a later period than the life of Snorri Sturluson.

The three oldest mss of the *Prose Edda* all belong to the beginning of the 14th century. The Wurm ms was sent to Ole Wurm in 1628, the *Codex Regius* was discovered by the indefatigable bishop Brynjólfur Sveinsson in 1643. The most important, however, of these mss is the *Uppsala Codex*, an octavo volume written probably about the year 1300. There have been several good editions of the *Edda Snorra Sturlusonar*, of which, perhaps, the best is the edition published by the Arnemagnæan Society in Copenhagen in 1848-52, edited by a group of scholars under the direction of Jón Sigurðsson, and the more recent Danish (1900) and Icelandic (1907) editions of Finnur Jónsson. There are English translations by T. Percy, *Northern Antiquaries*, from the French of P. H. Mallet (1770), by G. Webbe Dasent (Stockholm, 1842), by R. B. Anderson (Chicago, 1905), by A. G. Brodeur (1916). The last-named version contains the whole of the *Prose Edda*, with the exception of the very technical and

practically untranslatable *Hattatal*

The *Elder Edda*, *Poetic Edda* or *Saemund's Edda* *hinn fröða* was entirely unknown until about 1643, when it came into the hands of Brynjólfur Sveinsson, who, puzzled to classify it, gave it the title of *Edda Saemundis multis*. Saemundur Sigfusson, who was thus credited with the collection of these poems, came of an old and distinguished Icelandic family, and lived from about 1056 to 1133. The poems themselves are many of them only fragments of longer heroic chants now otherwise entirely lost. They treat of mythical and heroic legends of an early Scandinavian civilization, and are composed of the simplest and most archaic forms of Norse verse. They present many difficult problems upon which scholars have expended an inexhaustible but not always conclusive erudition.

It may be said with some confidence, however, that the 34 poems usually included in the *Edda* were composed between the 9th and 12th centuries, and that they were the composition of poets, whose very names are unknown, but who were certainly Norwegians by birth or descent and shared the same religious and poetic convention. These poets were not uncultured, they were affected by the beliefs of the Christianized peoples of western Europe, they used as material for their art Danish and German legends, they were influenced by the Anglo-Saxon and Irish literatures. Irish influence is marked in *Kræfþula*, to what extent it affected the *Edda* as a whole is debatable. The honour of having been the home land of the *Edda* has been claimed in turn for Norway, Iceland, the British Isles and Denmark. The two *Athi* poems can be assigned with certainty to Greenland, *Grimmsdál* appears from internal evidence to have been composed in Norway, and *Grípissþula* in Iceland. *Risþula* may have been composed in Ireland or in northern England. The meaning of the title "*Edda*" is still in doubt, it has been variously explained by scholars as "Tales of a Grandmother," "Poetics," "The Book of Oddi"—Saemundur resided at Oddi—"Poems of Death and Destruction," from the Irish word *ath*, signifying "deaths." The poems appear to have been collected from oral tradition and committed to writing in the 12th century, probably in Iceland and possibly by Saemundur.

The most remarkable of the poems in this priceless collection is the *Völuspá*, or prophecy of the *Völva* or Sibyl. In this chant we listen to an inspired prophetess, "seated on her high seat, and addressing Odin, while the gods listen to her words." She sings of the world before the gods were made, of the coming and the meeting of the Aesir, of the origin of the giants, dwarfs and men, of the happy beginning of all things, and the sad ending that shall be in the chaos of Ragnarok. The melodies of the verse, exquisite in their extreme and severe simplicity, are wholly rhythmical and alliterative, and return upon themselves like a solemn incantation.

Hávamál, the Lesson of the High One, or Odin, follows, this contains proverbs and wise saws, and a series of stories, some of them comical, told by Odin against himself.

In *Hyndluljóð*, the Lay of Hyndla, the goddess Freyja rides to question the *völva* Hyndla with regard to the ancestry of her young paramour, Ottar. With this poem, the first or wholly mythological portion of the collection closes. What follows is heroic and pseudo-historic. The *Völundarkviða*, or Song of Volund, is engaged with the adventures of Volund, the smith-ling, during his stay with Nidud, king of Sweden. Volund, identical with the Anglo-Saxon Wieland and the German Wieland (O.H.G. *Weland*), is sometimes confused with Odin, the master smith. This poem contains the beautiful figure of Svanhvit, the swan-maiden, who stays seven winters with Volund, and then yearning for her fatherland, flies away home through the dark forest. *Holgakviða Hjörvarðssonar*, the Song of Helga, the Son of Hjorvard, celebrates the wooing of Helgi of Svava, who like Atalanta, ends by loving the man with whom she has fought in battle. Two Songs of Helgi the Hunting's Bane, *Holgakviða Hundingsbana*, open the long and very important series of lays relating to the heroic families of the Volsungs and the Nibelungs. A very curious poem is the Song of the Sun, *Solarlof*, which forms a kind of appendix to the *Poetic Edda*. In this the

spirit of a dead father addresses his living son, and exhorts him, with maxims that resemble those of *Hávamál*, to righteousness of life. Though found only in the 17th century copies of the *Edda*, *Solarlof* appears from internal evidence to have been written in the 11th century, and to have been the composition of a Christian mystic who had not completely shed heathen modes of thought and expression.

The principal ms of this *Edda* is the Codex Regius in the royal library of Copenhagen, written continuously, without regard to prose or verse, on 45 vellum leaves. This is that found by Bishop Brynjólfur. Another valuable fragment exists in the Armaghman collection in the University of Copenhagen, consisting of four sheets, 22 leaves in all. These are the only mss older than the 17th century which contain a collection of the ancient mytho-heroic lays, but fragments occur in various other works, and especially in the *Edda* of Snorri. The text of the *Poetic Edda* has been edited by Möbius, Sophus Bugge, Hildebrand, Symons and Gerner, Finnur Jonsson, Neckel Dittler and Heintel (1903), and Sievers (1923). Twelve poems from the *Poetic Edda* were translated into English verse by Amos Cottle in 1797, the poet Gray produced a version of the *Völuspá* in 1797, but the first translation of the whole was that published by Benjamin Thorpe in 1866. The most recent English versions are those of Olive Rieu (1908) and H. A. Bullows (1923).

The Ldric poems were rearranged, on a system of their own which differs entirely from that of the early mss by Gudbrand Vigfusson and E. V. Rieu, in their *Corpus poeticon boreale* (1883). This is a collection not of *Edda* only, but of all existing fragments of the vast literary literature of ancient Iceland.

(X, R P Co)

EDDINGTON, SIR ARTHUR STANLEY (1882-1944)

British astronomer. He was born at Kendal, England, Dec. 28, 1882. He was educated at Owen's college, Manchester and Trinity college, Cambridge, where he was Senior Wrangler in 1904 and Smith's Prizeman in 1907. In the latter year he was elected fellow of his college. From 1906 to 1913 he held the post of chief assistant at the Royal observatory at Greenwich, and in 1913 he became Plumian professor of astronomy at Cambridge. In 1914 he was made director of the observatory at Cambridge, and in the same year was elected fellow of the Royal Society.

He was a member of many British and foreign scientific societies and was awarded the Hopkins prize of the Cambridge Philosophical society (1918-21), the Pontecoulte prize of the French Academy (1919), the gold medal of the Royal Astronomical Society (1924), the Bruce medal of the Astronomical Society of the Pacific (1924), and others. He was knighted in 1930 and was awarded the Order of Merit in 1938.

Eddington's principal researches were on the motions of stars, stellar evolution and relativity. His first published paper in 1906 was on the systematic motion of stars, this was followed during the next nine years by a series of papers on the structure of the heavens. "The Systematic Motions of the Stars of Professor Boss's Preliminary General Catalogue" appeared in 1910, in this paper Eddington analyzed this catalogue of 6,188 stars and some of his later researches were based on this analysis. In 1916-17 he published papers on "the radiative equilibrium of the stars," dealing with the interior of a star. Eddington grasped the significance of the theory of relativity at an early stage of its development, and, by means of articles, books and lectures, gave a clear exposition of the theory.

Eddington died Nov. 22, 1944.

His published works include *Stellar Movement and the Structure of the Universe* (1912), *Report on the Relativity Theory of Gravitation* (1918), *Space, Time and Gravitation* (1920), *The Mathematical Theory of Relativity* (1921), *Stars and Atoms* (1921), *The Expanding Universe* (1933), *New Pathways in Science* (1935), *Relativity Theory of Protons and Electrons* (1936) and *The Philosophy of Physical Science* (1939). (See RELATIVITY.)

EDDIUS or **ÆDDI**, a Kentish choirmaster, was employed by Wilfrid (c. 634-709), bishop of York, to organize services in Northumbria. His *Life of Wilfrid* is the earliest extant work of an Anglo-Saxon author. It is invaluable for its period, though strongly partisan in feeling, and was used by Bede for his *Histories*.

See Eddius, *Vita Wilfridi* (Räme, *Historians of Church of York*, London, 1879-84, 14), ed. with trans. and notes by B. Colgrave (Cambridge, 1927), Bede, *Hist. Eccl.* (ed. Plummer, Oxford, 1896), II, 2.

EDDY, MARY BAKER (1821-1910), the founder and leader of the Christian Science movement, was born on July 16, 1821, at Bow, near Concord, New Hampshire, USA. She was the youngest of the six children of Mark Baker and Abigail Ambrose Baker. Her father was a man of local prominence, first at Bow and later at Tilton, New Hampshire, a landowner, a justice of the peace, a member of the committee having charge of the public schools and a deacon of the Congregational Church. Her mother was the daughter of Deacon Nathaniel Ambrose, of Pembroke, New Hampshire, who also represented the same type of citizenship.

In 1843 Mary Baker married Major George W. Glover, a native of Concord, New Hampshire, but a resident of Charleston, S.C. By occupation a contractor and builder, he had an honorary title "by appointment to the staff of the governor of South Carolina." Major Glover died six months after their marriage while they were at Wilmington, N.C. Her only child (also named George W. Glover) was born three months later, after she had returned to New Hampshire. During the next nine years she lived at Tilton, New Hampshire, with her father, or with her sister Mrs. Abigail Tilton, and occupied herself to the extent allowed by delicate health in caring for her child and in teaching. For a time she conducted a private school for young children, at other times she was an extra teacher in a New Hampshire Conference Seminary.

In 1853 Mary Glover married Dr. Daniel Patterson, of Franklin, N.H., a dentist. This marriage proved to be extremely unfortunate. After ten years of alternate care and neglect, he finally deserted her at Lynn, Mass., whither they had removed from New Hampshire. Ten years later (at Lynn, in 1873) she obtained a divorce from him for desertion following after adultery. In 1877 Mrs. Glover (Mrs. Patterson having resumed this name) married Asa Gilbert Eddy, of Lynn, an ardent Christian Scientist and the first of her followers to engage in the public practice of Christian Science. After his death (at Lynn, in 1882) Mrs. Eddy continued as a widow until she died at Chestnut Hill, Mass., near Boston, on Dec. 3, 1910.

Considering that educational facilities for women were limited when Mrs. Eddy was young and that her attendance at school was interrupted by delicate health, the education she obtained was exceptionally liberal. In addition to attending ordinary schools, she attended the Academy at Tilton and received instruction from tutors. An extensive reader of good literature, she also wrote acceptable poetry and prose which appeared frequently in New England publications long before her discovery of Christian Science. After her discovery of Christian Science, she contributed the principal literature of this subject, employing for this purpose a distinctive literary style, as well as a notable ability to elucidate metaphysical and religious topics.

As a child and as a young woman, Mrs. Eddy showed an exceptional interest in religious subjects. In the development of this interest she was aided by her devout and intelligent mother, as well as by the Congregational pastors at Bow and Tilton and by other ministers whom her parents frequently entertained. At the age of 12, she had the courage and independence to dispute a point in theology when she was examined for church membership. Between then and her first marriage, she often discussed religious topics with her parents and with ministers, exhibiting a comprehension which they regarded as remarkable. Shortly before her first marriage, one of her pastors who also tutored her for six or seven years (Rev. Enoch Corser) predicted for Mrs. Eddy a great future and spoke of her as "an intellectual and spiritual genius."

The beginning of Mrs. Eddy's interest in religious or spiritual healing can be traced to an incident which occurred when she was 12 years old, immediately before her examination for admission to the Congregational Church. During a fever her mother commended prayer to God. Then, as Mrs. Eddy has related, "I prayed, and a soft glow of ineffable joy came over me. The fever was gone, and I rose and dressed myself, in a normal condition of health" (*Retrospection and Introspection*, p. 13). This incident, together with others of an extraordinary nature, is believed to have contributed to the observation and study which resulted

ultimately in Mrs. Eddy's discovery of Christian Science.

Mrs. Eddy regarded her discovery of Christian Science as resulting directly and immediately from an incident which occurred at Lynn in 1866. While returning from a meeting of Good Templars, she fell on an icy street and was injured severely. Carried to a nearby residence, she was attended by a physician and cated for during the night. The next day she was removed to her home, as a local newspaper reported at the time, "in a very critical condition." On the third day after this injury, having obtained little or no relief, Mrs. Eddy asked for her Bible, opened it so that she read an account of Christian healing (Matt. 9:2) and again experienced an immediate recovery.

Concerning the study which then ensued, Mrs. Eddy has written: "The Bible was my textbook. It answered my questions as to how I was healed, but the Scriptures had to me a new meaning, a new tongue. Their spiritual significance appeared, and I apprehended for the first time, in their spiritual meaning, Jesus' teaching and demonstration, and the Principle and rule of spiritual Science and metaphysical healing,—in a word, Christian Science."

Mrs. Eddy's published works on Christian Science began with a pamphlet copyrighted in 1870, entitled *The Science of Man*, of which only one small edition was printed. In this pamphlet she said, "In the nineteenth century I affirm for all time the word *Science to Christianity, and error to personal sense*, and call the world to battle on this issue." Her principal work, the Christian Science textbook, first entitled *Science and Health* but after ward entitled *Science and Health with Key to the Scriptures*, was issued in 1875. Occasionally revised by the author, "only to give a clearer and fuller expression of its original meaning," and finally revised in 1907, this book continues to be the fundamental and standard statement of Christian Science. Other published works by Mrs. Eddy include *The People's Idea of God* (1886), *Christian Healing* (1886), *Unity of Good* (1891), *Rudimentary Divine Science* (1891), *Retrospection and Introspection* (1891), *No and Yes* (1891), *Church Manual* (1895-1910), *Miscellaneous Writings* (1896), *Christ and Christmas* (1897), *Christian Science versus Pantheism* (1898), *Pulpit and Press* (1898), *Messages to The Mother Church* (1900, 1901, 1902), *The First Church of Christ, Scientist, and Miscellany* (1913).

Naturally, Mrs. Eddy was the first practitioner and the first teacher of her religion. As a practitioner, she demonstrated her religion by healings in many cases, until duties which could not be left to others required all of her time. As a teacher, she taught students until she was obliged to leave class teaching to students whom she selected for this work. She began to organize the Christian Science movement in 1876 when she and a few of her students formed the Christian Science Association. After three years she and a selected number of her followers organized the Church of Christ, Scientist, into which the earlier Association was merged. In 1892, she and a selected number of her followers organized the Christian Science mother church, the First Church of Christ, Scientist, in Boston, which succeeded the earlier church. The Mother Church, together with the branch churches or local congregations throughout the world, constitutes the present organization. In 1892 Mrs. Eddy also founded the Christian Science Publishing Society as an agency of her church.

Next to what Mrs. Eddy did as the discoverer and founder of Christian Science, her greatest work was done as the leader of the Christian Science movement. Although living a rather secluded life (at Lynn until 1882, in Boston from then until 1889, at Pleasant View, near Concord, N.H., from then until 1908, and afterward at Chestnut Hill, near Boston), she initiated and either directed or supervised every important activity of her Church, and she formulated the plan, set forth in the *Church Manual*, by which its affairs are to be conducted permanently. From the general point of view, Mrs. Eddy was a remarkable woman, for it was no light task to propose a new system of religious philosophy which was at the time and is even now so radically at variance with much of prevailing orthodox beliefs. She was 57 when she founded the Church of Christ, Scientist, which in half a century extended its branches throughout the world totalling (1928) 2,370 churches and societies. She followed this with the founding of the *Chris-*

tion Science Journal, a monthly magazine which she edited for 11 yrs., and 15 yrs later she founded the *Christian Science Sentinel*, a weekly. In 1908, when Mrs Eddy was 87, she established the *Christian Science Monitor*, a successful daily news paper, giving news free from sensation and scandal. Nor did Mrs Eddy, at these times, relinquish her other activities. Her own life illustrated and demonstrated her proposition that "prayer, watching and working combined with self immolation, are God's gracious means for accomplishing whatever has been successfully done for the Christianization and health of mankind" (*Science and Health*, p. 1). See CHRISTIAN SCIENCE (C P S).

EDE, a town in the province of Gelderland, the Netherlands, on the railway Utrecht-Amhem. Pop. (1940) 34,567. Ede is the seat of the important Dutch Enka ryon silk industry. At 3 mi distance is the castle of St Hubertus, containing the modern art collection of Krollier Muller, which gained special fame for its outstanding collection of paintings by Vincent Van Gogh.

EDELINCK, GERARD (1649-1707), Flemish copper plate engraver, was born in Antwerp on Oct. 20, 1649. He learned the rudiments of the art in his native town under Gaspard Huybrecht. He then went to Paris in 1665 and worked under de Poilly. On the recommendation of Le Brun, he was appointed teacher at the academy established at the Gobelins to train workers in tapestry.

Edelincx with Nanteuil and Masson formed the great triumvirate of the best period of French portrait engraving. He excelled in rendering light and shade, colour and the texture of surfaces. He was the first to execute prints in the lozenge shape. Among his works, which number 341, are a "Holy Family," after Raphael, a "Penitent Magdalen," after Charles le Brun, "Alexander at the Tent of Darius," after Le Brun, a "Combat of Four Knights" after Leonardo da Vinci, "Christ Surrounded by Angels," "St. Louis Praying," and "St. Charles Borromeo before a Crucifix"—the last three after Le Brun. Edelincx engraved portraits of Louis XIV, Le Brun, Rigaud, Philippe de Champagne (which the engraver thought his best), Santeuil, La Fontaine, Colbert, John Dryden, Descartes, etc. He died in Paris on April 2, 1707. His two brothers, Jean and Gaspard François, and his son Nicolas, were also engravers, but did not attain to his excellence.

See H. Delaborde, *Gérard Edelincx* (1886), Robert Dumesnil, *Le graveur français*, vol. vii (1835-71).

EDELWEISS (*Leontopodium alpinum*), a perennial plant of the composite family (*Compositae*), native of the Alps and the Andes. It is a small herb reaching about 6 in. high, with narrow white woolly leaves and terminal flowerheads enveloped in woolly bracts. The woolly covering is assumed to protect the plant, in the exposed situations in which it is found, by preventing its drying up through excessive loss of moisture. It is much sought after by some visitors to the Alps but although rather sporadic in its distribution it is not rare and grows readily in gardens under lowland conditions.

EDEN, SIR ASHLEY (1837-1924), Anglo-Indian official and diplomatist (third son of Robert John Eden, third Lord Auckland and bishop of Bath and Wells), was born on Nov. 13, 1837, and entered the Indian civil service in 1852. In 1855 he helped to suppress the "mutiny" and from 1860 to 1871 was secretary to the Bengal government with an *ex officio* seat on the legislative council. Eden was (1871) the first civilian governor

of British Burma, in 1877 he became lieutenant-governor of Bengal. He returned to England on his appointment (1882) to the council of the secretary of state for India, of which he remained a member till his death on July 9, 1887.

EDEN, though often used as the name of the garden in which, according to Gen. 11 and 12, lived the first man created, is strictly the name of the region in which that garden was situated. The garden contained beautiful fruit trees providing food for the man whom God had appointed to till it. In it, too, were "the tree of the knowledge of good and evil" and "the tree of life," magical trees conferring upon those who ate of their fruit wisdom and immortality. The man and his wife were expelled from the garden because, having tasted, contrary to the divine command, of the fruit of the former, God feared that they might eat also of the other tree's fruit. The story blends many mythological conceptions which belong to the primitive age of Semitic religion. Close study of the story reveals that it is compounded of at least two traditions, one concerned with the tree of knowledge, the other with the tree of life. Prof. H. T. Obbink of Utrecht has suggested that the narrative has been generally misunderstood. His view is that the tree of life was really intended to furnish divine food by which the first man maintained his immortality, and that he was evicted from the garden to cut him off from this nourishment.

Many speculations have been made as to the site of the garden, which seems to be thought of as an oasis in a barren region. According to Gen. 11:8 it was "eastward" verses 10-14 describe a river as flowing forth from it, and dividing into four streams. One of these is the Euphrates, and another, "Hiddekel," almost certainly the Tigris. This would suggest a site north of Babylon. It is true that the Euphrates and the Tigris near Baghdad approach so closely together that the former discharges water through canals into the latter. But even if it be supposed that these two rivers might be regarded as coming from a common source no satisfactory explanation of the two remaining rivers is offered. To define the site from these details is impossible, it is obvious, moreover, that verses 10-14 are a learned note intruded into the simple story. The attempt to locate a mythological garden is bound to be attended by considerable difficulty, and all that can be safely said is that the story in its present form combines two traditions, one of which placed the garden in the far east, the other in the far north, where, according to Babylonian tradition, the garden of the gods was to be found. Yet another tradition as to the garden, which underlies Ezek. xxxvii 12-19, connects it with the mountain of God, placed by Isa. xiv 13 in the "sides of the north." (W. L. W.)

EDENBRIDGE, a market town in the Sevenoaks parliamentary division of Kent, England, 2½ mi SSE of London on the Southern railway, and 10 mi W of Tonbridge on the line to Redhill. Pop. of civil parish (1931) 3,254. It is pleasantly situated on the river Eden, an affluent of the Medway, in a valley between the Ragstone hills and the Forest ridges, on the Surrey border. The church of St Peter and St Paul is principally perpendicular. The town has considerable agricultural trade and a chalybeate spring which is little used. Hever castle, 2 mi SW, is a beautiful moated mansion of the 15th and 16th centuries, but occupying the site of an earlier structure. This was rebuilt by Sir Geoffrey Boleyn, whose grandson, Sir Thomas, was father of Anne, second wife of Henry VIII, who here spent much of her life before her marriage and was visited by the king. There is a chapel of her family in the fine parish church of Hever. Not far distant is the modern Chiddingstone castle, on an ancient site. A block of sandstone in the park is called the "chiding stone," tradition asserting it to be a prehistoric seat of judgment.

EDEN HALL, LUCK OF, an old painted or enamelled glass drinking goblet preserved at Eden Hall, Cumberland, the seat of the Musgrave family, perhaps of the 16th century. It has the letters IHS on the top. Round the vase is the verse given below. In the grounds of Eden Hall is a spring called St. Cuthbert's Well, and the story is that one of the early Musgraves surprised the faeries making merry at the well, and seized the goblet from the fairy king, who eventually acknowledged his

EDELWEISS A HANDSOME WOOLLY PLANT FOUND IN THE ALPS OF CENTRAL EUROPE. OFTEN GROWN IN ROCK GARDENS.

defeat and gave him the cup, but warned him

When this cup shall break or fall,
Farewell the luck of Eden Hall

Possessed of the cup, the knight of Musgrave is said to have at once prospered in a love suit. There is a poem on the cup called "The Drinking Match at Eden Hall," by Philip, duke of Wharton, a parody on the ballad of Chevy Chase, reprinted in Edward Walford's *Tales of Great Families* (1877, vol. x), as "The witty Duke of Wharton."

EDENKOBEN, a town of Germany, in the Bavarian palatinate, 6 mi. N from Landau, on the railway to Weissenburg. Population 5,218. It has a sulphur spring. Its industries comprise ironworks, and the manufacture of machinery, furniture and cigars. It has also a large trade in wine and is frequented for the grape-cure.

EDENTATA, an order of Mammalia (*q.v.*) comprising the sloths, anteaters and armadillos restricted to the warmer parts of America. But this name, meaning toothless, applies only to the anteaters. The teeth of sloths and armadillos, however, are abnormal in being of persistent growth, seldom differentiated, without enamel and invariably absent in the front of both jaws. A character distinctive of the order is the presence of accessory articular processes on some of the vertebrae. From this the name *Xenarthra* has been given to these groups to distinguish them from the pangolins and aardvarks of the old world which were formerly associated with the American edentates as *Nomarthra* on account of the normal construction of the vertebrae. There is, however, no evidence of kinship between the anteaters of the old and new worlds, such resemblances as they exhibit being superficial adaptations to diet. The pangolins and aardvark are therefore dealt with separately in this article.

The existing edentates are divided into two suborders, the Pilosa or Anicanodonta and the Lorica or Hicanodonta.

Pilosa.—In the Pilosa the anus and external genitalia are close together on a common eminence or enclosed in a fold of skin, both the clitoris and penis being quite short, and there is no exoskeleton of dermal bones. There are two well defined groups, the Tardigrada or sloths and the Vermilingua or anteaters. In the Tardigrada the jaws are short, strong, and the wide mouth is provided with teeth and a short flat tongue, the tail is short or absent and the limbs are long and slender, the fore and hind feet are similar in being long and narrow and in having the two or three digits compactly united and furnished with long, curved, equal claws. In the skull the zygomatic arch is branched.

The existing sloths feed upon leaves and are entirely arboreal. Their limbs are especially modified to enable them to climb or hang back downwards on branches, and their long coarse hair harbours microscopic green algae which serve to conceal them in the trees.

The sloths are referred to two subfamilies, the Bradypodinae and Choloepinae. In the Bradypodinae, or three-toed sloths, all the feet are furnished with three digits, and the soles are almost entirely hairy, there is a distinct tail, the hair on the head grows forward, forming a fringe round the face, the nostrils are small and the ears very simple. Sometimes known as aye-ayes, they are found in the tropical forests of South and Central America. The few known species are referred to two genera, *Bradypus* and *Scaevops*.

The Choloepinae or two-toed sloths, also known as unau, have only two digits on the forefoot, the soles are quite naked, there is no external tail, the hair on the head grows backwards, the nostrils have a thickened margin and the ear is provided with a valvular flap. The single genus *Choloepus*, represented by a few species, ranges from Nicaragua to Brazil.

In the Myrmecophagidae or anteaters the snout is elongated and down-curved, the mouth has a very short gape, a long worm-like tongue and no teeth, the fore and hind feet are dissimilar and the digits of the forefoot are unequal in size, the third being the largest and armed with a great falcate claw and the tail is very long. In the skull the jaws are weak and the zygomatic arch is slender and unbranched. The anteaters are assigned to two subfamilies, the Cyclopedinae and Myrmecophaginae.

In the Cyclopedinae, containing only *Cyclopes didactylus*, the silky or two-toed anteater, the limbs are adapted essentially for climbing. The forefoot has only two digits with strong claws which close upon a large cushion-like pad, the hind foot has four fused digits, each with a long claw, and capable of folding down on to the heel for grasping, the tail is prehensile and naked at the tip beneath but otherwise covered, like the head and body, with long silky hairs which on the head conceal the simple ears. The jaws and other parts of the skull are less specialized than in the next family. This little arboreal anteater, which is no bigger than a rat, is found in tropical South and Central America.

The Myrmecophaginae contain two very distinct forms, the great anteater (*Myrmecophaga jubata*) and lesser anteater or tamandua (*Tamandua tetradactyla*). The feet are adapted for progression on the ground although in the tamandua they also serve for climbing. The forefoot has four clawed toes, and on its outer side a large supporting pad, the hind foot has five toes with short claws, and is plantigrade, the hair is not silky and on the head is quite short so that the better developed ears are prominent. The skull differs from that of *Cyclopes* in having a weaker mandible and in the fusion of the pterygoids to prolong the nasal passages. In the tamandua the tail is prehensile and covered mostly with small scales and short hairs, the hair of the body is short and smooth and the forefoot has a large carpal pad confluent with the ambulatory pad. This anteater, which is about the size of a cat, lives in the forests of tropical America.

The great anteater (*Myrmecophaga jubata*), standing over two feet high, is purely terrestrial in habits. The hair on the body and tail is long, shaggy and coarse, the tail is rigid and not prehensile, the forefoot has a very large ambulatory pad and a small isolated carpal pad and the snout is much longer than in the tamandua. It lives in the swampy savannas and forests of tropical America, feeding, like the other anteaters, mainly on termites the nests of which it rips open with the great falcate claws of the fore feet.

Loricata.—In the Loricata the external genitalia are long and not associated with the anus, as in the Pilosa, there is a dermal bony exoskeleton and the hairy covering is usually scanty. The armadillos which constitute this suborder are divisible into several subfamilies.

In the Dasypodinae the bony exoskeleton consists of a head-shield, one or more free bands on the neck, a large compact scapular shield enclosing the fore quarters, followed by from 6 to 13 free dorsal bands and a large solid pelvic shield over the hind quarters, the scutes of these areas being tolerably alike in size and shape, the flexible tail tapers to a point and its bony rings never consist of more than two rows of scutes, the skin of the lower surface is scanty hairy and tubercular, the legs are scaly above and there are five toes on each foot, those of the fore foot being provided with fossorial claws, the fourth toe being the longest, while on the hind foot the third and fourth are subequal and all the claws are smaller, the ears are large, situated on the sides of the head some distance behind the eyes.

There are two tribes, the Dasypodini and the Cabassini. The Dasypodini have from six to eight dorsal bands, one neck band, the scutes are coarsely sculptured, and the tail has jointed rings. To this subfamily belong the six-banded armadillo (*Dasypus sexcinctus*) of Paraguay and Brazil, and many related species. A remarkable Brazilian species (*Scleropleura bruneti*) has the dermal scutes defective, especially on the back. These armadillos are active animals of small or medium size, ranging in length of head and body from about six inches in the pigmy to a foot or rather more in the six-banded armadillo.

In the Cabassini there are from 11 to 13 dorsal and from three to four neck bands, the scutes are often polished, the scutes of the tail are not arranged in distinct rings and may be defective, and the forefeet are more fossorial, the claws of the third or third and fourth being specially enlarged. To this group belong the tatouay (*Cabassous unicinctus*) of Brazil and Surinam, and the giant armadillo (*Protonotus gigas*) of Brazil, which may reach a length of three feet.

The subfamily Tatunae contains the peba or nine-banded arma-

dillo (*Tatu* or *Tatusia*) which differs from the Dasypodinae in having the ears set close together on the top of the head no bands on the neck, the scutes of the dorsal bands larger and differently shaped from the small scutes of the scapular and pelvic shields, the bands on the long tail are composed of three rows of scutes, in the fore foot the fifth toe is absent and the third is as large as or larger than the fourth, and the five toes of the hind foot are symmetrically arranged, the third being median. The genus ranges from Texas to the Argentine and is represented by a few species of which the best known is *Tatu novemcincta*. A rare species, the hairy peba (*T. pilosa*), is remarkable for having a coat of long hair concealing the scutes. It has been referred to a distinct genus *Cryptopractus*.

To the subfamily Tolypeutinae belong the apurú or bill armadillos, so called from their power to roll up into a compact sphere. In adaptation to this protective habit there is beneath the very large pelvic and scapular shields a deep recess into which the limbs can be withdrawn. The tail is very short and rigid. They also differ from the Dasypodinae in having from two to four dorsal bands and in being more digitigrade, the second, third and fourth toes of the hind foot which have broad hoof like claws, and the tips of the long claws of the third and fourth digits of the fore foot resting on the ground during progression. The toes vary from five to three. A few species of the genus *Tolypeutes* are admitted. The best known is the common three-banded armadillo (*T. tricinctus*) from the Argentine.

The little silky armadillo or pichichiago (*Chlamyphorus tridactylus*) the type of the subfamily Chlamyphorinae, differs from all existing armadillos in having a continuous series of scutes, forming transverse bands, extending from the head shield to the pelvic shield, the latter forming a vertical semicircular disc giving a truncated appearance to the hinder end of the body, in having the dorsal bands attached to the body along the middle of the back and overlapping its sides, which, like the ventral surface and legs, are clothed with silky hair, like a cloak, in the reduction of the ear to a tiny lobe close to the eye and in having the tail spatulate. The feet nearly resemble those of the Dasypodinae but have larger falcate claws. This armadillo, which is found in the sandy deserts of the Argentine, is an expert digger and largely subterranean in habits. A related genus, *Burmeisteria*, found in Bolivia, differs in having the shell adherent to the sides of the body and the bony scutes of the pelvis shield defective.

Extinct Edentates.—The fossil remains of edentates, found in abundance in Tertiary deposits of North and South America, show that the existing sloths, anteaters and armadillos are the widely divergent survivors of a great, and now waning group represented in the past by large numbers of highly diversified genera, some of the species of which were colossal in bulk. Some of these fossils serve to link in a measure, not only the sloths with the anteaters, but the armadillos with both these groups.

Taking first the Pilosa, the discovery of sloths and anteaters differs, but little from existing species in Pleistocene deposits of South American lands only, passing reference of former writers to the former sloths, the Gravigradis standing between the Trigradids and the Vermivora with skulls and teeth in the former and the rest of the skeleton more as in the latter. The kno in genera are grounded round three main types: *Megatherium*, *Myodon* and *Megalonyx*.

Megatherium had a long, very strong tail, broad hips and very stout hind limbs, with a huge heel and only three toes, the third alone being armed with a large claw, the fore limbs were long and strong and four toed, the second, third and fourth toes being armed with claws, that of the third being exceptionally large, there were well developed collar bones, the skull had interiorly protruding massive jaws, with a chisel shaped zygomatic arch. There is no doubt that this great bear, measuring 18 ft long, the skull being about two feet long upon foliage and ways which he reached by rearing up against a tree trunk supported on his hind legs and tail, and using his fore legs to pull down the branches, and a long flexible tongue to gather the leaves into his mouth. It also seems clear that in standing and walking on the ground he rested on the outer side of both fore and hind feet. The remains

of *Megatherium* itself are found in Pleistocene deposits of the southern United States and South America. Related forms occur in the Pliocene of Argentina, and considerably smaller forms, regarded as ancestral, occur in Miocene beds of Patagonia.

Myodon, although smaller, with the skull about a foot and a half long, closely resembled *Megatherium* in general form, but had weaker, short jaws, differently shaped, smaller teeth, and five toes on the fore foot and four on the hind, but evidently walked on the outer side of both feet, like *Megatherium*. Its remains are found in Pleistocene beds of North and South America. There are many related genera, also Pleistocene. Of particular interest was *Glossotherium* on account of the presence of bones in the skin beneath the hair, recalling the exoskeleton of the armadillos. Supposedly ancestral forms of *Myodon* and its allies are found in Miocene deposits of Patagonia.

Megalonyx, with the skull a foot or more in length, found in Pleistocene and Pliocene deposits of North America, is distinguished from the preceding genera by having the first of the five upper teeth large, tusk like and isolated. A large number of related genera from Miocene deposits in Patagonia are smaller and less specialized.

It is amongst the earlier Miocene forms of Gravigrada that we find evidence of convergence between the sloths and anteaters. Not only are they smaller than the later evolved forms but also their limbs are more slender and their feet more normal, in the number and size of the digits, and in the hind feet being plantigrade, as in the great anteater.

With regard to the Loricae, many existing genera occur in the Pleistocene of Argentina and Brazil, and Pleistocene and Pliocene beds have yielded remains of a huge armadillo (*Chlamydotherrum*), comparable to a rhinoceros in size and with teeth less simplified than in surviving species. A large number of genera approximating to existing forms have also been found in Miocene and earlier deposits in Patagonia. One of these, *Stegotherium*, is of particular moment from possessing long, narrow jaws with a few minute, simple teeth at the back of the mouth, thus approaching the long jawed toothless anteaters. But excelling all in interest are the Glyptodonts, a group of extinct, highly specialized armadillos distinguished by having the entire body encased in an unjointed bony carapace, in the fusion of the vertebrae of the back, the peculiar jointing of the neck so that the head could be withdrawn into the shell, and in the structure of the skull which was remarkably like that of *Megatherium*, in general appearance. To support the great weight of the carapace the feet were short and broad with hoof like nails especially on the hind feet, and the long tapering tail was jointed, with bony rings in its basal portion and encased in an unjointed sheath at the end. Some of these armadillos, like *Glyptodon* and *Panochthus*, from the Pleistocene of South America, were eight or nine feet long and about four feet high and they moved about slowly, grazing on herbage like huge tortoises. They died out in the Pleistocene, but the group is traceable through the Pliocene back to Miocene deposits of Patagonia.

Another group of extinct mammals, shown by the structure of their vertebrae to belong to the edentate stock, is the Taeniodonta or Glondonts whose remains occur in Lower and Middle Eocene deposits in North America. In the structure of the skull and of the massive limbs this suborder shows considerable resemblance to the Gravigradids, but although the median molar teeth, both above and below, seem to be missing, the rest of the dentition is quite unlike that of typical edentates in being heterodont, with large canines and cuspid, usually rooted cheek teeth, all more or less covered with enamel. The best known forms are *Conoryctes*, *Pastacotherium* and *Hemiganus*.

The Lower Eocene of North America has yielded yet another group, the Pliacodonts (*Pliacodon*, *Metachromys*), which has been claimed to be ancestral to the edentates. It is said to resemble the Loricae in the structure of the feet and other respects, such as the absence of molar teeth, but differed in the absence of dermal bones and of cheek-teeth and the presence of large cutting canines. Since, moreover, the vertebrae were normally constructed and there was no union between the poste-

rior part of the pelvis and the anterior vertebrae of the tail such as is found in all typical Edentata, it is difficult to justify this classification

PHOLIDOTA

The pangolins (*q v*) or scaly anteaters of Africa and tropical Asia were at one time associated with the Edentata mainly on account of their likeness to the South American anteaters in the absence of teeth, the weakness of the jaws, the enlargement of the salivary glands, and the length of the vermiform, extensible tongue, and to the armadillos in the possession of a hard dermal exoskeleton. But the resemblances to the former group are adaptive and due to similarity of diet and the exoskeleton is of a totally different type from that of the armadillos, since it consists of large, erectile, overlapping horny scales, composed of cemented hairs, there being no trace of bony matter in the skin. They show, indeed, no resemblances to the edentates of any systematic importance and differ from them fundamentally in many characters, such as the absence of extra articular processes in the spinal column, the presence of a bicornuate, instead of a globular, uterus, of a diffused, non deciduate, instead of a dome-shaped deciduate, placenta, etc.

The head is short and conical, with functionless facial vibrissae and a most normal rhinarium as in *Myrmecophaga*, the ear sometimes has a distinct pinna but may be represented by a vertical slit only. The legs are short but the feet vary in structure according to habit. The fore foot has five toes of which the second, third and fourth are always armed with large claws, the largest being on the third, the first and fifth digits are very variable in size and are usually small clawed. The hind foot also has five toes which vary in size and in the size of the claws. The tail is also variable, sometimes being excessively long and prehensile, sometimes comparatively short and forming, with the hind legs, a kind of tripod support, at other times it is intermediate in structure. The anus and external genitalia are situated close together on an eminence formed mainly by the enlarged anal glands, and the anus is sunk in a depression into which the ducts of the glands open, both the penis and clitoris are quite small.

Pangolins range in Asia from north India and south China to Ceylon and Borneo and in Africa from Sierra Leone and Uganda to the Cape. There are several different kinds. Some are almost entirely arboreal, some purely terrestrial, while others which live in the main on the ground also climb trees as well. Otherwise their habits are very similar. They feed mostly on termites, ripping open the nests of these insects with the strong claws of the fore feet. Their means of defence are the emission of a repulsive odour from the large anal glands and rolling into a compact ball with the hard, often sharp, erected scales presented to the enemy and protecting the soft skinned hairy underside of the body from injury.

There are several species and genera, all referred to the family Manidae. But this is divisible into three sub-families. In the Asiatic species, the Maninae, the hinder end of the sternum or breast-bone is shaped like the blade of a spade, having a convex posterior edge and two forwardly directed spiniform angles. To this group belong the north Indian and Chinese eared pangolin (*Manis pentadactyla*), the Indian and Ceylonese thick tailed pangolin (*Phatagius crassicauda*) and the Javanese and Bornean pangolin (*Paramanus javanicus*), which differ in many external characters.

In the African pangolins the end of the breast-bone is prolonged into two long rods running back to the posterior ribs. There are two well defined sub-families differing in habitat and correlated structural characters. The Smutsinae, containing the genus *Smutsia* with the two species *temminckii* and *gigantea*, are terrestrial with the feet and tail adapted for ground life, and the Phataginae, containing the two small west African pangolins, *Phatagius tricuspis* and *Uromanus longicauda*, which differ from all other pangolins in being adapted to arboreal life, their tails being exceedingly long and prehensile, and the feet with only four functional toes, the upper side of the fore foot being without scales.

Extinct Pangolins.—Bones of a large pangolin, indistinguishable from the African giant pangolin, have been found in a cave in Madras, in Lower Pliocene deposits of Samos occur *Palaeomamus* and earlier still are *Leptomamus* and *Necromamus* from the Upper Eocene phosphorites of Query.

TUBULIDENTATA

To the order Tubulidentata belongs the aardvark (*q v*) or African antbear, *Orycteropus*, representing the family Orycteropodidae, which was formerly associated with the American edentates and the scaly anteaters because, feeding on termites, it has a longish snout, a long, extensible tongue, a small gape, no teeth in the fore part of the jaws and cheek teeth defective in enamel and of persistent growth. In no other respects does it resemble the edentates, and although it is like the scaly anteaters (Pholidota) in having normally articulated vertebrae and a bicornuate uterus, these are characters common to many orders of mammals. The aardvark is a burrowing, heavily built animal, about six feet long, scantily covered with hair, with a long narrow head carrying huge rabbit like ears and ending in a swollen mobile snout with terminal valvular nostrils closed with long hair. The tongue, although long, is not vermiform. The feet are powerful and very much alike except that the fore foot has no first toe, the toes are long, armed with huge flattened claws, and the second and third, which are the longest, are united by a deep and wide web, the fore foot is plantigrade, the hind digitigrade. The tail is long, stout and tapering, and the external genital organs are situated on a pleural eminence containing a pair of scent glands opening at the sides of the short penis and of the vulva, which is provided with a cordate flap-like clitoris. The teeth of the permanent set are unlike those of other mammals in being traversed by many tubules radiating from a central pulp cavity. They represent molars and premolars, the latter having milk predecessors, but in the newly born young traces of incisors and canines which never cut the gum have been discovered. There is evidence indeed that the ancestor of *Orycteropus*, before degeneration of the teeth set in, had no fewer than three incisors, one canine, five premolars and five or six molars on each side above and below, a larger number than is found in any order of mammals with typical heterodont dentition.

Aardvarks are found in Africa south of the Sahara both in deep forest and in the open. It is doubtful if more than one species is still in existence.

Extinct Aardvarks.—A species, *O. gaudryi*, nearly allied to the living forms, occurs in Lower Pliocene deposits of Bessarabia and Samos, and a distinct genus, *Palaeorycteropus*, has been recorded from the Upper Eocene phosphorites of Query. Finally, it may be added, certain bones from the Miocene of Europe have been claimed to indicate a common ancestry for the armadillos, scaly anteaters and aardvarks, but the indications are too doubtful to be trusted. (R ! P, X)

EDENTON, a city of northeastern North Carolina, U.S., on an inlet of Albemarle sound, near the mouth of the Chowan river, the county seat of Chowan county. It is served by the Norfolk Southern railroad and by bus and river transportation. The railroad bridge across Albemarle sound is 4.8 mi long. Pop (1950) 4,454, (1940) 3,835. Shad and herring fisheries are an important industry, and there is a U.S. fish hatchery near by. The city is a large peanut and watermelon market. Edenton has some fine old homesteads and many historical associations. It was settled about 1658, and through the 18th century was a place of considerable social and political importance. The legislative assembly met here occasionally, and here lived the royal governors and various prominent citizens of the province, including Joseph Hewes, James Iredell, father and son, and Samuel Johnston. St. Paul's church was built in 1736, the court-house in 1767. In a house facing the court house the "Edenton Tea Party" was held on Oct. 24, 1774, by 51 ladies, who signed resolutions that they would refrain from using tea or anything manufactured in England until the tax on tea should be repealed. On May 5, 1864, a naval engagement was fought near Edenton between the Confederate ram "Albemarle" and the Union "Sassacus," a wooden side wheeler, resulting in favour of the Confederate ironclad.

EDESSA, the ancient capital of Macedonia (an older name is *Aegae*), situated 46 m W of Thessalonica on a beautiful stream in the centre of the kingdom, commanding the approaches from the coast to the interior. It was the original residence of the Macedonian kings, and after the seat of government was removed by Philip II to the more accessible Pella, it continued to be the royal burial place. At the celebration of his daughter's marriage here, Philip II was murdered by Pausanias in 336 B.C. Though Alexander was buried at Alexandria the bodies of Eurydice and her husband Arrhidæus were removed by Cassander to the ancestral sepulchre. On the occupation of the town by Pyrrhus the royal tombs were plundered by Gallic mercenaries. Owing to its position commanding the Via Egnatia the town retained its importance during the Roman and Byzantine periods. For its present condition, see *VOYAGE*.

EDESSA, the Greek name of an ancient city of N.W. Mesopotamia (in 37° 21' N lat and 39° 6' E long.), suggested perhaps by a comparison of its site, or its water supply,¹ with that of its Macedonian namesake. It still bears its earlier name, *Urhai*, modified since the 15th century (by the Turks?) to *Urfa*.

The oldest certain form is the Aramaic *Urhāi* ("Western" pronunciation *Urhāi*), which appears in Greek as in adjective as *ὀρραῖος*, *-ωδ* (perhaps also as a fortress with spring, as *Oppā*), and in Latin as *Or(h)es*,² and (in the inscription on Abgar's grave) *Orhēnoru(m)*.³ The Syriac Chronicle ascribed to Dionysius of Tell-mahrē derives the name from a first king *Urhāi*, son of Hewyā (i.e. "Snake"), but neither this nor any other derivation hitherto suggested is satisfactory. The distinct name *Osrōnē* (for *ὀρραῖος*) is in Syriac *Bēth Urhāyē*. The Arabs pronounced the name *er Rūhā*, and this form prevailed till it gave place to *Urfa* in the 15th century.

According to Pliny, v. 86, Edessa was also called Antioch, and coins of Antiochus IV. Epiphanes with the legend "Antioch on the Callirhoe" may imply that he rebuilt and renamed the place. (So Ed Meyer in Pauly-Wissowa, *Realencyclopädie*, col. 1933, 66). Pliny indeed seems to call the city itself Callirhoe, but K. Regling (*Klio*, i. 459, n. 1) may be right in his emendation which applies the title in Pliny to the sacred spring.

History—Edessa *Urhāi* is important mainly as the earliest seat of Syriac-speaking Christianity. About 132 B.C., when the Hellenistic empire of the Seleucids was breaking up, a native non-Greek dynasty succeeded in establishing a more or less independent State with Edessa as its capital on what came to be the frontier between the Roman and the Parthian dominions. The names of some 30 local kings survive, but little is known of its history, and the true tale of the planting of Christianity in this region is lost in the mists of legend. In A.D. 114 king Abgar VII. entertained Trajan on his way back to Syria (Dio Cass. xviii. 21), but in 116 after a general rising the Consul L. Quetus sacked the city and made the State tributary. Hadrian, however, restored the dynasty of Edessa, but made it a dependency of Rome. When L. Verus (163–165) recovered Mesopotamia from Parthia, it was not Edessa but Harrān that was chosen as the site of a Roman colony and made the metropolis by Marcus Aurelius (172). The fact that these decisive events have left no trace in the Christian traditions suggests that Christianity had not yet arrived at Edessa. The native religion of Edessa, according to Christian tradition, was connected with the Planets. In the *Doctrine of Addai* 24 Venus appears to be called Bath Nīkal, a name for Ishtar of Babylonian derivation ("daughter of Nin Gal" see C. Winkworth in *J. Th. St.* xxv. 402). One or both of the pools below the citadel containing sacred fish may have been sacred to Atargatis (q.v.), an Ishtar-Venus deity. In the citadel itself are still standing two pillars—there may once have been more—both 50 ft high, on one of them is a pre-Christian Syriac inscription, which states that it was set up for Shamlat the queen, daughter of Ma'nu.

the viceroy (pāgriba), together with a bas relief or statue, now effaced. The fact that this inscription is in Syriac is a testimony to the Semitic tone of the culture of the little state, "Syriac," in fact, is the dialect of Aramaic then spoken in Edessa and its neighbourhood.

Before Christianity arrived at Edessa the more important parts of the Old Testament had been translated into Syriac by Jews, either at Edessa itself or in Adiabene under the encouragement of the then reigning house (Josephus, *Bell. Jud.* ii. 19, 4). This translation, slightly revised and supplemented, is still used by the Syriac speaking churches and is known as the Peshitta (i.e. the Simple version). Tradition connects the founding of Christianity in Edessa with Addai, a missionary sent by St. Thomas himself, who converted Abgar the king and many of the inhabitants. As, however, he is also said to have brought the Gospel in the form of the Diatessaron, and we know from Epiphanius (*Haer.* 46) that Tatian, the author of the Gospel Harmony called *Diatessaron*, returned to his Mesopotamian fatherland about 170 as a missionary, it seems reasonable to identify "Addai" with Tatian himself (see *J. Th. St.* xxv. 128–130). About the end of the 2nd century Edessene Christianity seems to have made a fresh beginning, the ordination of Palut by Serapion of Antioch may mean that things ecclesiastical took a westward turn, and it is possible that a complete version of the Four Gospels (the "Old Syriac") was now introduced. Mention should here be made of Bardaisan (q.v., Bardesanes) known as the Aramaean philosopher. He became a Christian, and is famous for his cosmological speculations (see C. W. Mitchell, *Ephraim's Refutations*, p. cxxii ff.), but was reckoned heretical. He was a contemporary of Abgar IX., at whose court Julius Africanus stayed for a while. A Syriac official record from this reign, preserved in the *Edessene Chronicle*, gives a somewhat detailed account of a violent flood (Nov. 201) of the Dāsān river which did much damage, destroying amongst other things "the palace of Abgar the Great," rebuilt as a summer palace by Abgar IX., and "the nave of the church of the Christians." The form of this last statement shows that at the time of writing (206) the rulers had not adopted Christianity themselves. Abgar IX. is now commonly supposed to be the ruler to whom the famous legend was first attached (see *ABGAR*), but though he visited Rome there is no proof that he ever became a Christian (Gomperz, in *Archäologisch-epigraphische Mittheilungen aus Österreich-Ungarn*, ix. 154–157). It was at Edessa that Caracalla, who made it a military colony (Colonia Marcia Edeessenorum), spent the winter of 216–17, and near there that he was murdered. The religious philosophical treatise known as the *Book of the Laws of Countries* was produced at this time by a pupil of Bardesanes. The *Acts of Thomas* in its original form may have followed not long after: this work contains the finest Syriac poem extant, commonly called the "Hymn of the Soul." Bardesanes has been conjectured to have been its author on insufficient grounds (see Mitchell, *op. cit.*, p. cxxix).

Sassanian Period—In 226 the Parthian empire gave place to the new kingdom of the Sassanidae, whose claim to the ancient Achaemenian empire led to constant struggle with Rome in which Edessa naturally suffered. The native State was restored by Gordian in 242, but in 244 it became again directly subject to Rome. The legendary Edessan martyrs Sharbēl and Barsamya may have perished in the Decian persecution. In 260 the city was besieged by the Persians under Shapur I., and Valerian was defeated and made prisoner by its gates. Odaenathus of Palmyra (d. 267), however, wrested Mesopotamia from the Persians, but Aurelian defeated his successor Zenobia at Emesa (273), and Carus, who died in 283 in an expedition against the Persians, and Galerius (297) carried the frontier again to the Tigris. During the Diocletian persecution Shmōnā, and Garia (Nov. 15, 309) and Habbib (Sept. 2, 310), the "Confessors of Edessa" were martyred, but the bishop Qōna, who laid the foundations of "the great church" by the sacred pool, somehow escaped. Edessa can claim no share in "the Persian Sage" Aphrahat (Aphraates), but Ephrem, after bewailing in Nisibis the sufferings of the great Persian war under Constantius and Julian, when Jovian in 363 ceded most of Mesopotamia to Shapur II., the persecutor of the

Christians, settled in Edessa, which as the seat of his famous school (called "the Persian") grew in importance, and attracted scholars from elsewhere. He taught and wrote vigorously against the Arians and other heretics, and although just after his death (373) the emperor Valens banished the orthodox from Edessa, they returned on the emperor's death in 378. Rabbula, bishop of Edessa from 411 to 435, was a great organizer, but he won from the Nestorians the title of the Tyrant of Edessa. In particular he exerted himself to stamp out the use of the Diatessaron in favour of the four Gospels, of which he issued a revised Syriac translation, which is the final form of the Peshitta. The sojourn in Edessa of the "Man of God" (Alexis) belongs to Rabbula's episcopate, and the oldest surviving dated Syriac ms was written in the year he became bishop. When Nestorianism was condemned at Ephesus (431) it began to gravitate eastwards, Nisibis becoming its eventual headquarters, but Edessa and the western Syrians refused to bow to the Council of Chalcedon (451) when it condemned Monophysitism.¹ Zeno's edict (486) ordered the closing of the school of the Persians at Edessa, and East and West drifted apart more and more, Narsai, the leading Nestorian teacher, fled to Nisibis about 489. Till about this time Syriac influence was strong in Armenia, and some Syriac works have survived only in Armenian translations. In the opening years of the 6th century the Persian-Roman War (502-506) found a chronicler in the anonymous Edessene history known till recently as the Chronicle of Joshua Stylites. Whether Edessa received from the emperor Justin I the additional name of Justinopolis may be uncertain (see Hallier, *op cit* p. 128), but it seems to have been renewed and fortified after the "fourth" flood in 525 (Procop. *Pers* II 27, *De aedific* II 7). About this time, according to Noldeke, an anonymous Edessene wrote the Romance of Julian the Apostate, which so many Arab writers use as a history. Chosroes I Anushirvān succeeded in 540, according to the last entry in the Edessene Chronicle, in exacting a large tribute from Edessa, but in 544 he besieged it in vain. A few years later Jacob Burd'ara (Baradaeus), with Edessa as his nominal bishopric, was carrying on the propaganda of Monophysitism which won for the adherents of that creed the name of Jacobites (see JACOBITE CHURCH). The valuable Syriac Chronicle just referred to probably was compiled in the latter half of this century.

Islam—In the first decade of the next century Edessa was taken by Chosroes II, and a large part of the population transported to eastern Persia. Within a score of years it was recovered by the emperor Heraclius, who reviewed a large army under its walls. The prophet of Islam was now, however, building up his power in Arabia, and a few years later (636?) Heraclius's attempts, from Edessa as a centre, to effect an organized opposition to the victorious Arabs were defeated by Saïd, and he fell back on Samosāta. The terms on which Edessa definitely passed into the hands of the Moslems (638) under Riyad are not certain (Balādihuri). As it now ceased to be a frontier city it lost in importance. In 668 occurred another destructive flood (Theophanes, p. 537), and in 678 an earthquake which destroyed part of the "old church," which the caliph Mo'awiya I is said to have repaired. To the latter part of the century belongs the activity of Edessa's bishop Jacob, whose chronicle is unfortunately lost. It may have been the impulse given by the final supremacy of the caliphate to the long process which eventually substituted Arabic for Aramaic (which had now prevailed for a millennium and a half), that led Jacob to adopt Greek vowel signs for use in Syriac. Yet a century later Theophilus of Edessa (d. 785), author of a lost history, translated into Syriac "the two books of the poet Homer on the conquest of the city of Ilion." When the Baghdad caliphs lost control, Edessa shared the fortunes of western Mesopotamia, changing with the rise and fall of Egyptian dynasties and Arab chieftains. In the 10th century al-Mas'ūdi, writing in the very year in which it happened, tells how the Mohammedan ruler of Edessa, with the permission of the caliph, purchased peace of the emperor Romanus Leapenus by surrendering to him the napkin of Jesus of Nazareth, wherewith he had dried himself

after his baptism. The translation of the Holy Icon of Christ from Edessa is commemorated on Aug. 16 (Cal. Byzant.). A few years later Ibn Haukal (978) estimates the number of churches in the city at more than 300, and al-Muḥaddasi (985) describes its cathedral, with vaulted ceiling covered with mosaics, as one of the four wonders of the world. In 1031 the emperor recovered Edessa, but in 1040 it fell into the hands of the Seljuks, whose progress had added a large element of Armenian refugees to the population of Osrohoene. Magrizi tells us that the Armenian minister Badr al-Gamālī employed architects from Edessa to build three of the fine city gates of Cairo (1087-91). The empire soon recovered Edessa, but the resident made himself independent. In 1098, in the First Crusade, Baldwin, brother and successor of Godfrey of Bouillon took possession of the town and made it the capital of a Burgundian countship, which included Samosāta and Sarūg, and was for half a century the eastern bulwark of the kingdom of Jerusalem.¹ The local Armenian historian, however, Matthew of Edessa, tells of oppression, decrease of population, ruin of churches, neglect of agriculture. With the campaign of Maudud in 1110 fortune began to favour the Moslems. Edessa had to endure siege after siege. Finally, in 1144 it was stormed, Matthew being among the slain, by Imād ud-Din Zengi, ruler of Mosul, an achievement celebrated as "the conquest of conquests," for which an Edessan monk, John, bishop of Harrān (d. 1165) laid the responsibility not on God but on the absence of the Frankish troops. Edessa suffered still more in 1146 after an attempt to recover it. Churches were now turned into mosques. The consternation produced in Europe by the news of its fate led to "the second Crusade." In 1182 it fell to Saladin, whose nephew recovered it when it had temporarily passed (1234) to the sultan of Rūm, but the "Eye of Mesopotamia" never recovered the brilliance of earlier days. The names it contributed to Arabic literature are unimportant. By timely surrender (1268) it escaped the sufferings inflicted by Hülākū and his Mongols on Sarūg (Barhebraeus, *Chron Arab*, Beirut ed. 486). Mostaufi describes a great cupola of finely worked stone still standing by a court over a hundred yards square (1340). Alī b. Yazd in his account of the campaigns of Timur, who reduced Mesopotamia in 1303, still calls the city (1425) Rūhā. In 1637, when Amurath IV. conquered Baghdad and annexed Mesopotamia, it passed finally into the hands of the Turks, by whom it is called Urfa.

Burkitt, *Euphrates and the Gosh*, (1913), p. 46, that in Wright's *Joshua*, taken from Niebuhr (1780), is not to be trusted owing to wrong identifications of the Gates. (F. C. B.)

Modern City—The city occupies an important position as one of a line of frontier forts which hold the entrance from the foothills to the plain. It is in addition an important point of transit along the northern and safer route from Mosul to Aleppo, being now on the railway. At this point the land routes westwards divide, one going south to Aleppo, another west to Adana. It is the centre of a wheat district but is not concerned in any industry. The population is uncertain, it probably numbers about 40,000 and includes Kurds, Turks and Armenians.

The town itself is of considerable interest. It is surrounded by a wall, with square towers at intervals. On the western part of the town lies the old citadel, with two great Corinthian columns, known as the "throne of Nimrod." Between the citadel and the town are the springs, from which it probably derived its name of *Callirhoe*. The water from these springs forms two ponds, on the edge of the larger of which is the great Mosque of Abraham. The largest mosque however is in the middle of the town, probably on the site of the once famous Christian church. The Kara Kuyun (*Σκιππος*) runs in a moat round the town, and this and the other streams serve to irrigate the gardens, vineyards and mulberry orchards. In addition to its stormy history in earlier times Edessa towards the end of the last century incurred an unfor-

¹The oldest surviving dated ms of a portion of the Bible in any language was written at Amid (Diarbekr) in A.D. 464.

fortunate reputation as the seat of Armenian massacres

EDFU, in Coptic *Atbā*, a town of Upper Egypt, 484 m S S E of Cairo by rail, on the W bank of the Nile, the railway station being on the opposite side of the river. The inhabitants manufacture earthenware, which finds ready sale all through Egypt. The ancient *Atbā* (*Apollinopolis Magna*) was capital of the second nome of Upper Egypt. The great Ptolemaic sandstone temple is practically complete. The central part of the building, begun by Ptolemy III Euergetes in 237 B.C., was finished by his successor in 212, the portico, courts, pylons and surrounding wall were added by Ptolemy Ptolemy II, Soter II and Alexander I, but the decoration was not finished till c. 100 in the reign of Ptolemy XIII Neos Dionysus. The god of Atbā was a form of Horus (Apollo) as the sun god, his most characteristic representation is as the disk of the sun with outstretched wings. Population 15,000.

EDGAR (*Eadgar*) king of the English (901–957), was the younger son of Edmund the Magnificent and Aelfgifu. As early as 955 he signed a charter of his uncle Eadric, and in 957 the Mercian nobles, discontented with the rule of his elder brother Eadwig, made him king of England north of the Thames. On the death of his brother in Oct. 959 Edgar became king of a united England. Immediately on his accession to the throne of Mercia Edgar recalled St Dunstan from exile and made him first bishop of Worcester, and then of London. In 961 Dunstan was translated to Canterbury, and throughout Edgar's reign he was his chief adviser, and to him must be attributed much of the peace and prosperity of this time.

The reign of Edgar was somewhat uneventful, but two things stand out clearly: his ecclesiastical policy and his imperial position in Britain. Edgar and Dunstan were alike determined to reform the great monastic houses, to restore them to their true owners, and to remove them from the lax discipline of the secular priests or *canonici*. The priests of the old and new monasteries at Winchester, Chertsey and Milton Abbas were replaced by monks, and the old rule of St Benedict was strictly enforced.

The coronation of Edgar, delayed for some unexplained reason till 973, took place with much ceremony at Bath, and was followed shortly after by the submission of eight kings, including the kings of Scotland and Strathclyde, to Edgar at Chester. In 967 an outbreak against Edgar in Northumbria was put down by Thored, the son of Gunner, steward of the king's household.

Edgar's death took place in the year 957, and he was buried at Glastonbury. By his vigorous rule and his statesmanlike policy Edgar won the approval of his people, the only fault ascribed to him is a too great love for foreigners and for foreign customs. Edgar strengthened the hands of the provincial administration, and allowed the northern Danes a certain degree of self government.

Edgar is said to have formed an irregular union in 961 with Wulfthryth, an inmate of the convent at Wilton, who bore him a daughter Eadgyth but refused to marry him. He married Aethelflaed, "the white duck," daughter of Earl Ordmar, who bore him a son, known as Edward the Martyr. Finally he was united (964) to Aelfthryth, daughter of Earl Ordgar, who became the mother of the Aetheling Edmund (d. 971) and of Aethelred the Unready.

See *The Anglo-Saxon Chronicle* (ed. Plummer, 1892–99), *sub ann.*, *Vita Sancti Oswaldi* (*Historians of the Church of York*, ed. Raine, Rolls Series), William of Malmesbury, *Gesta regum* (ed. Stubbs, Rolls Series), Birch, *Cartularium Saxonicum*, vol. II Nos 1047–1310, F. Liebermann, *A-S Laws*, 1 192–216, "Florence of Worcester" (*Mon Hist Brit*), E. W. Robertson, *Historical Essays*, pp. 189–215.

EDGAR or **EADGAR** (c. 1050–c. 1130), called the Aetheling, was the son of Edward (the exile), a son of the English king Edmund Ironside, by his wife Agatha, a kinswoman of the emperor Henry II, and was born probably in Hungary some time before 1057, the year of his father's death. After the death of Harold in 1066, Eadwine and Morkere desired to make him king, but on the advance of William I, Edgar and his supporters made their submission. He took part in two unsuccessful risings in the north (1068 and 1069), afterwards taking refuge in Scotland, where his sister Margaret married the Scottish king, Malcolm Canmore. In 1074 he went to Normandy and made peace with William. In 1097 he made a successful attempt to set his nephew

Edgar on the throne of Scotland, and in 1099 went to the crusade. He returned to England in Henry I's reign, but sided with Robert of Normandy against the king in their last war, and was taken prisoner at the battle of Tinchebrai in 1106. He was soon released, and lived in obscurity until his death, the date of which is uncertain.

EDGECEUMBE or **EDGECOMBE**, the name of a celebrated west of England family, taken from the manor of Edgecombe in Cornwall. One of its earlier members was Sir Richard Edgecombe (d. 1489), who was descended from a Richard Edgecombe who flourished during the reign of Edward I. Richard was a member of parliament in 1467, afterwards he joined Henry, earl of Richmond, in Brittany, returned with the earl to England, and fought at Bosworth, where he was knighted. He was richly rewarded and sent by Henry VII on errands to Scotland, Ireland and Brittany, he died at Morlaix on Sept. 8, 1489. His son and successor, Sir Piers Edgecombe (d. 1539) went to France with Henry VIII in 1513. His son Sir Richard Edgecombe (1499–1562), a cultured and hospitable man, is celebrated through Richard Carew's *Friendly Remembrance of Sir Richard Edgecombe*. Sir Richard's eldest son, Piers or Peter Edgecombe (1536–1607), was a member of parliament under Elizabeth for about 30 years.

Another famous member of this family was Richard, 1st baron Edgecombe (1680–1758), a son of Sir Richard Edgecombe. Educated at Trinity college, Cambridge, he was successively member of parliament for St Germans, Plympton and Lostwithiel from 1701 to 1742, on two occasions served as a lord of the treasury, and from 1724 to 1742 was paymaster general for Ireland, becoming chancellor of the duchy of Lancaster in 1743. He managed the elections for the Cornish boroughs in the interests of Sir Robert Walpole and his elevation to the peerage, which took place in 1742, was designed to prevent him from giving evidence about Walpole's expenditure of the secret service money. His son and successor, Richard, the 2nd baron (1716–61), was comptroller of the royal household, a member of parliament, and a major general in the army.

Richard's brother George (1721–95), was a naval officer during the Seven Years War. Succeeding to the barony on the 2nd baron's death in 1761 he became an admiral and treasurer of the royal household, was created Viscount Mount Edgecombe in 1781 and earl of Mount-Edgecombe in 1789.

EDGE HILL, an elevated ridge in Warwickshire, England, near the border of Oxfordshire. The north western face is an abrupt escarpment of the Lias, and the summit of the ridge is almost level for nearly 2 m, at a height somewhat exceeding 700 ft. The escarpment overlooks a rich lowland watered by streams tributary to the Avon, the gentle eastern slope sends its waters to the Cherwell, and the ridge thus forms part of the divide between the basins of the Severn and the Thames. Edge Hill gave name to the first battle of the Great Rebellion (1642), fought on the 23rd of October 1642.

EDGE TOOLS. A general term which includes cutting and scraping tools, as distinguished from those of percussive type, as hammers, and of lever type, as spanners. Edge tools date from the remote palaeolithic age when rough axes were chipped from flints, to be improved by neolithic men who ground and polished their celts. The true chisel, thrust by hand, appears to have developed in the bronze age. The basic difference between an axe and a chisel is that the one is doubly bevelled, the other singly. The result is that the axe does not possess good guidance on the wood, while the flat face of the chisel acts as a guide, helping to cut true surfaces. An adze is of the chisel class, and is used by the carpenter and shipwright to true baulks and other large areas. The carpenter's plane gives still better control by means of the sole sliding along the wood, while in machine tools for wood and metal the guidance becomes perfect.

The keenness of an edge tool, or its "cutting angle" is nearest to that of the razor in the woodworker's chisels, gouges, carving-tools and plane irons, as well as in certain machine knives. Hard or tough wood tends to turn over a fine edge or break it, consequently the angle of the two faces meeting at the edge must be

increased. The same rule applies to cold chisels for metals. In the tools used in metal working machines, as the lathe, drill, planer, shaper and slotter and the milling and sawing machines, the edges must be ground more keenly for the fibrous metals and alloys, as wrought-iron, mild steel and copper, but less keenly for the crystalline kinds, as hard steel, cast iron and brass. Chilled cast iron, for the rolls of rolling mills, is very difficult to turn, and the tool faces meet at an angle of near 90°, the action being merely slow scraping. Nevertheless this tool is a wedge, in principle, just as much as the finest chisel for soft wood, penetrating and forcing aside the metal (See also FILE, MACHINE KNIVES, MACHINE TOOLS, MILLING CUTTERS, PUNCHING AND SHEARING MACHINES, SAWS, and general article Tool.)

EDGEWORTH, MARIA (1767-1849), Irish novelist, second child and eldest daughter of Richard Lovell Edgeworth (qv) and his first wife, Anna Maria Eilers, was born in the house of her maternal grandparents at Black Bourton, Oxfordshire, on Jan. 1, 1767. She had ample opportunities for society among her father's neighbours in Ireland, among whom were the second Lord Longford, whose daughter, "Kitty" Pakenham, became later duchess of Wellington, Lady Moura at Castle Forbes, and Maria's aunt, Margaret Ruxton, at Black Castle. She gained a first-hand experience of the Irish peasantry by acting as her father's assistant in the management of the estate. The Edgeworths were in Ireland from 1793 onwards through that dangerous period, and Maria's letters, always gay and natural, make very light of their anxieties and their real perils.

It has been the fashion to regard Mr Edgeworth's influence over Maria's work as altogether deplorable, but she undoubtedly derived a stimulus from his powerful mind. Her first publication was a plea for the education of women, *Letters to Literary Ladies* (1795), and in 1796 appeared *The Parent's Assistant* (2nd ed., 6 vols., 1800), a collection of stories which had been submitted as they were written to the juvenile critics of the Edgeworth nursery. They were therefore children's stories for children, even though the morals were Mr Edgeworth's *Practical Education* (2 vols., 1798) was written in conjunction with her father, who also collaborated with her in the *Essay on Irish Bulls* (1802). Miss Edgeworth's first novel, *Castle Rackrent*, appeared anonymously in 1800. It is the story of an Irish estate and its owners, the Rackrents, as told by Thady, the steward. Its success was immediate, and a second edition soon appeared with the author's name. The personages appear to be drawn immediately from the natives of Edgeworthstown, though Miss Edgeworth asserts that only Thady himself was an actual portrait. The book influenced Scott. In the "Postscript, which should have been a preface," in the original edition of *Waverley*, Scott describes his aim as being "in some distant degree to emulate the admirable Irish portraits of Miss Edgeworth, so different from the 'Teagues' and 'dear joys' who so long, with the most perfect family resemblance to each other, occupied the drama and the novel." *Belinda* (1801) is a society novel, and one of her best books. Saintsbury thinks that Miss Austen's heroines owe something of their naturalness to *Belinda*, who was one of the earliest to break with the tradition of fainting and blushing. *Moral Tales for Young People* (5 vols.) and *Early Lessons*, which included "Harry and Lucy," "Rosamond" and "Frank," appeared in 1801.

In 1802 the Edgeworths went abroad, first to Brussels and then to Paris. They had already connections in Paris through their kinsman, the abbé Edgeworth de Firmont, who was, however, then in exile. They met all the notabilities in Paris, and Maria refused an offer of marriage from a Swedish count named Edelcrantz. Although *Leonora*, not published until four years later, is said to have been written to meet his taste, she apparently remained then and always heart whole, but her stepmother thought otherwise and maintained that she suffered severely for her decision (*Memoir*, 1. 144). Returning to Edgeworthstown, Miss Edgeworth resumed her writing, which was always done in the rooms commonly used by the whole family. *Popular Tales* was published in 1804, and *The Modern Griselda* in the same year, *Leonora* in 1806, and in 1809 the first series of *Tales of Fashionable Life*, three volumes containing "Ennui," "Madame

de Fleury," "Almeria," "The Dun" and "Manoeuvring," the second series (3 vols., 1812) included "The Absentee," one of her best tales, which was originally designed as a play, "Vivian" and the clever study of emigre life, "Émilie de Coulinges." In 1813 Maria and her parents spent a considerable time in London, and her society was much sought after. When *Waverley* was published, Miss Edgeworth received a copy from the publishers, and at once recognized the authorship. She wrote a long letter of appreciation (Oct. 23, 1814) to "the author of *Waverley*," which she began with the phrase *ut Scotus, ut dubitabam*, but the letter was merely acknowledged by the publishers. *Patronage* (4 vols., 1814), the longest of her novels, and *Harrington, a tale*, and *Ormond, a tale* (3 vols., 1817) complete the list of the works which received what her father called his *imprimatur*.

After his death in 1817 Miss Edgeworth occupied herself with completing his *Memoirs*, which were published in 1820. In 1820 she was again in Paris, and in 1823 she spent a fortnight with the Scotts at Abbotsford. In 1825 Scott went to Edgeworthstown, and their relations were always cordial. Miss Edgeworth's production was less after her father's death. Sequels to "Rosamond," "Frank," "Harry and Lucy" in the *Early Lessons* were published in 1822-1825. *Comic Dramas* appeared in 1817, and *Helen* in 1834. In 1846 she worked strenuously for the relief of the famine-stricken Irish peasants. She died on May 22, 1849.

Miss Edgeworth's novels are distinguished by good sense, humour and vivacious dialogue. She expressly calls some of her stories "Moral Tales," but the freshness of her stories, her insight into character, lively dialogues, originality of invention and delightfully clear style render it quite possible to read her works in succession without any sense of weariness.

See *A Memoir of Maria Edgeworth, with a Selection from her Letters* (1867), by her stepmother, F. A. Edgeworth, privately printed. A selection from this was made by Augustus J. C. Hare, and printed under the title of *The Life and Letters of Maria Edgeworth* (2 vols., 1894). See also *Maria Edgeworth* (1883), by Helen Zimmer, in the "Eminent Women" series, Grace A. Oliver, *A Study of Maria Edgeworth* (3rd ed., Boston, U.S.A., 1882), and *Maria Edgeworth* (1904), by the Hon. Emily Lawless in the "English Men of Letters" series. Also George Saintsbury in *Macmillan's Magazine* (July 1895), the preface supplied by Lady Thackeray Ritchie to Macmillan's edition of the novels (1895), C. Hill, *Maria Edgeworth and her circle* (1909), *The Black Book of Edgeworths Town* (1858-1817), ed. H. J. and H. E. Butler (1928).

EDGEWORTH, RICHARD LOVELL (1744-1817), British writer, was born at Bath. The greater part of his life was spent at Edgeworthstown, or Edgeworthstown, in the county of Longford, Ireland. He was educated at various schools in England and Ireland, and entered Trinity college, Dublin, in April 1761, but was transferred to Corpus Christi college, Oxford, in October of the same year. While still at college, he made a runaway match, marrying at Gretna Green, Anna Maria, one of the daughters of Paul Eilers of Black Bourton, Oxon, an old friend of his father. Edgeworth devoted much of his time to scientific reading and experiments, and he made an attempt to establish telegraphic communication (*Memoirs*, ed. 1. 144). In the pursuit of his mechanical inventions he visited Erasmus Darwin at Lichfield, where he met Anna Seward, and her cousin, Honora Sneyd. He kept terms at the Temple, and formed the greatest friendship of his life with Thomas Day, the author of *Sandford and Merton*, which was written at Edgeworth's suggestion. In 1769, on the death of his father, he gave up the study of law, and spent a considerable time in England and France, mainly in Day's company. He was summoned to England by the death of his wife (March 1773), with whom he had been far from happy. Edgeworth hurried to Lichfield, to Dr. Erasmus Darwin's, and at once declared his passion for Honora Sneyd, which had been the cause of his flight to France two years before. Miss Sneyd had been the object of attention from Thomas Day, but her views on marriage were not submissive enough to please him. She had other suitors, among them the unfortunate Major Andre. She married Edgeworth (July 1773), and after residing at Edgeworthstown for three years, they settled at Northchurch, in Hertfordshire. Honora Edgeworth died in April 1780, recommending her husband to marry her sister Elizabeth, and they

were actually married on Christmas day, 1780. She died in 1797.

Practical Education (1798) was written in collaboration with his daughter Maria, and embodied the experience of the authors in dealing with children. This book, generally regarded as old fashioned, has a real value in the history of education. Their views had been inspired by Rousseau, and by Thomas Day. The Edgeworths brought a scientific method to their work. The second Mrs Edgeworth (Honora Sneyd) began the collection of actual examples of conversations between the children and their elders. This was continued by the writers of the book, and their reasonings were thus founded on an accurate record of childish methods of thought. They deprecated especially any measures that interrupted the child's own chain of reasoning. The chapters on special subjects of study, chronology, geometry, etc., were written by Richard Lovell Edgeworth, those on toys, on rewards and punishments, on temper, etc., by his daughter.

In 1798 Edgeworth married Miss Beaufort, and was elected M.P. for the borough of St John's Town, Longford. During the formidable rebellion of that year the Edgeworths took refuge in Longford. The winter of 1802 they spent in Paris. In 1804 the government accepted his telegraphic apparatus, but the installation was left incomplete when the fear of invasion was past. In 1806 Edgeworth was elected a member of the board of commissioners to enquire into Irish education. From 1807 till 1809 much of his time was spent on mechanical experiments and in writing the story of his life. He died on June 13, 1817, and was buried in the family vault in Edgeworthstown churchyard. Edgeworth's works include *Poetry Explained for Young People* (1802), *Professional Education* (1808), *Readings in Poetry* (1816).

See *Memoirs of Richard Lovell Edgeworth, Esq.*, begun by himself and concluded by his daughter, Maria Edgeworth (4 vols, 1820, 3rd and revised ed, 1844). *Richard Lovell Edgeworth* (1806), edit Mrs Lionel Tollemache, is a selection from the *Memoirs*. See also *The Black Book of Edgeworthstown* (1585-1817), edit H. J. and H. E. Butler (1928).

EDGEWORTH DE FIRMONT, HENRY ESSEX (1745-1807), last confessor to Louis XVI, was the son of Robert Edgeworth, rector of Edgeworthstown in Ireland, his mother being a granddaughter of Archbishop Ussher. His father resigned his living and emigrated to Toulouse, where the boy was brought up by the Jesuits. On taking orders he assumed the additional surname of de Firmont, from the family estate of 1100 mount near Edgeworthstown. In 1791 he became confessor to the princess Elizabeth, sister of Louis XVI, and then to Louis himself. After Louis's condemnation he obtained permission to celebrate mass for him and attend him on the scaffold, where he recommended the king to allow his hands to be tied, with the words "Sire, in this new outrage I see only the last trait of resemblance between your Majesty and the God who will be your reward." The abbé himself denied that at the moment of the execution he uttered the celebrated words "Son of St. Louis, ascend to heaven." Edgeworth continued to correspond with Madame Elizabeth. In 1795, his mother having meanwhile died in prison, where his sister was also confined, he escaped to England, carrying with him Elizabeth's last message to her brother, the future King Charles X. He afterwards went with some papers to Monsieur (Louis XVIII), then at Blankenburg in Brunswick, and was induced to accompany him to Mittau, where, on May 22, 1807, he died of a fever contracted while attending some French prisoners.

EDGREN-LEFFLER, ANNE CHARLOTTE, duchess of Cajanello (1849-1892), Swedish author, daughter of the mathematician Prof C. O. Leffler, was born on Oct. 1, 1849. Her first volume of stories appeared in 1869, but the first to which she attached her name was *Ur Ljufvet* ("From Life," 1882), a series of realistic sketches of the upper circles of Swedish society, followed by three other collections with the same title. Her earliest plays, *Skådespelskan* ("The Actress," 1873), and its successors, were produced anonymously in Stockholm, but in 1883 her reputation was established by the success of her comedies *Sanna Kumor* ("True Women") and *En Riddande engel* ("An Angel of Deliverance"). *Sanna Kumor* is directed against false femininity, and was well received in Germany as well as in Sweden.

Anne Leffler had married in 1872 G. Edgren, but about 1884 she was separated from her husband, who did not share her advanced views. She spent some time in England, and in 1885 produced her play *Hur man gör godt* ("How Men do Good"), followed in 1888 by *Kampen för lyckan* ("The Struggle for Happiness"), a drama in which she had the help of Sophie Kovalevsky. Another volume of the *Ur Ljufvet* series appeared in 1889, (both volumes were reprinted in 1915, and *Familjeljufvet* ("Domestic Happiness," 1891), a drama in 3 acts, was produced in the year after her second marriage, with the Italian mathematician, Pasquale del Pezzo, duca di Cajanello. She died at Naples on Oct. 21, 1892. The masculine directness, freedom from prejudice, and frankness of her work gave her a high place in Sweden. Her last book was a biography (1892) of her friend Sophie (Sonya) Kovalevsky, by way of introduction to Sonya's autobiography. An English translation (1895) by A. de Funnhagen and A. M. Chive Bayley contains a biographical note on Fru Edgren Leffler by Lily Wolfson, based on private sources.

See also Ellen Key, *Anne Charlotte Leffler* (1893), O. J. Lewittin, *Swedish National Literature, 1500-1900*, vol. 18 (1907).

EDIBLE BIRD'S-NEST, the nest of a species of the swiftnest of the genus *Collocalia*, composed chiefly of the saliva of birds. They are to be found in the East Indies and Australia and are valued by the Chinese for the making of soup. The most important species is *C. fuciphaga*. See SWIFT.

EDICT, an order or proclamation issued under authority and having the force of law. The word is especially used of the promulgations of the Roman praetor (*q.v.*), of the Roman emperors, and also of the kings of France (see ROMAN LAW).

EDINBURGH (éd'in burí), the capital city of Scotland, county of a city, royal and parliamentary burgh and the county town of Midlothian or Edinburghshire south of the Firth of Forth, 393 mi. by rail N.W. of London. The old Royal observatory on Calton Hill stands in 55° 57' 23" N and 3° 10' 46" W. Edinburgh occupies a group of hills and valleys. In the centre is a bold rock, crowned by the castle, between which and the new town lies a ravine that once contained the Nor Loch, but is now covered with the gardens of Princes Street. To the east rises Calton Hill (355 ft.) with St. Andrew's house and the Calton cemetery. On the southeast is the hill of Arthur's Seat (822 ft.). Toward the north the site of the city slopes to the Firth of Forth and includes the port of Leith, while to the south, Liberton Brae, Blackford Hill, Braid Hills and Craiglockhart Hills roughly mark the city bounds, as Corstorphine Hill and the Water of Leith do the western limits. Its situation, general plan and literary associations gave Edinburgh the name of "the modern Athens," but it has a homelier nickname of "Auld Reekie," from the cloud of smoke (reek) over the low-lying quarters.

Chief Buildings—In the castle, the oldest building is St. Margaret's chapel, believed to be the chapel where Queen Margaret, wife of Malcolm Canmore, worshipped, and belonging at latest to the reign of her youngest son, David I (1124-1153). Near it the parliament and banquet hall contains a fine collection of Scottish armour, weapons and regimental colours. The heraldic bearings of royal and other figures distinguished in national history are emblazoned in the windows. Other buildings in the palace yard include the apartments occupied by the regent, Mary of Guise, and her daughter Mary, queen of Scots, and the room in which James VI was born. Here also are deposited the Scottish regalia ("The Honours of Scotland"), with the sword of state, presented to James IV by Pope Julius II, and the jewels restored to Scotland on the death (1807) of Cardinal York, the last of the Stuarts. The remains of King David's tower, the ancient keep, were hidden by the Half Moon battery, but were revealed in 1912. In the armoury is a collection of arms of various dates, and on the Argyll battery stands a huge piece of ancient artillery, called Mons Meg, of which repeated mention is made in Scottish history. The large arsenal on the west side of the rock is modern, but the castle garrison was withdrawn in 1923. A war memorial, a shrine and gallery of honour, was opened in Crown square in 1927 (See under MONUMENTS below.)

The palace of Holyrood house was originally an abbey of

canons regular of the rule of St Augustine, founded by David I in 1128, and the ruined nave of the abbey church still shows parts of the original structure. Connected with this is a part of the royal palace erected by James IV and James V, including the apartments occupied by Queen Mary, the scene of the murder of Rizzio in 1566. The abbey was sacked and burned by the English under the earl of Hertford in 1544, and again in 1547. Modern excavation revealed much of the early foundations. In a map of 1544 the present northwest tower of the palace is shown standing apart, and joined to the abbey by a cloister. Beyond this was an irregular group of buildings replaced later by additions more in accordance with a royal residence. The whole of this latter structure was destroyed by fire in 1650 while in occupation by the soldiers of Cromwell, and the more modern parts were begun during the Protectorate, and completed in the reign of Charles II by Robert Mylne, after the designs of Sir William Bruce of Kinross. They include the picture gallery, with 106 mythical portraits of Scottish kings, and a triptych (c. 1484) containing portraits of James III and his queen, believed to have formed the altar piece of the collegiate church of the Holy Trinity, founded by the widowed queen of James II in 1462, demolished in 1848, and afterwards rebuilt, stone for stone, in Jeffrey street. The picture gallery is associated with the festive scenes that occurred during the short residence of Prince Charles in 1745, and in it the election of representative peers for Scotland takes place. Escaping from France at the revolution of 1789, the comte d'Artois, afterwards Charles X of France, had apartments granted for the use of himself and his suite, who continued to reside in the palace till Aug. 1799. When driven from the French throne by the revolution of 1830, Charles once more found a home in the palace. The state apartments were redecorated under the guidance of Queen Mary, wife of George V. A fountain, after the original design of that in the quadrangle of Linlithgow palace, was erected in front of the entrance by the prince consort. Iron gates enclosing the forecourt, and a statue of Edward VII, form the national memorial to that king. The royal vault in the Chapel Royal, which was dilapidated, has been put in order. Clockmill house and grounds have been added to the area of the parade ground, and the abbey precincts generally and the approaches to the King's park have been improved. With the abolition of imprisonment for debt in 1882 the old privileges of sanctuary came to an end.

Parliament house, begun in 1632 and completed in 1640, in which the later assemblies of the Scottish estates took place until the dissolution of the parliament by the Act of Union of 1707, has since been the meeting-place of the supreme courts of law. The great hall, with its fine open-timbered oak roof, is adorned with a splendid stained-glass window and several statues, including one by Louis François Roubiliac of Duncan Forbes of Culloden, lord president of the court of session (1685-1747), and now forms the ante room for lawyers and their clients. The surrounding buildings, including the court rooms and the buildings for the Signet and the old Advocates' libraries, are modern. The Advocates' library was founded in 1682 by Sir George Mackenzie of Rosehaugh. It was presented to the nation by the faculty of advocates in 1924 and was endowed by Sir A. Grant with £100,000 for maintenance. It is one of the five entitled by the Copyright Act to receive a copy of every work published in Great Britain. The library is now the National Library of Scotland.

The General Register house for Scotland, begun in 1774 from designs by Robert Adam, stands at the east end of Princes street. It contains, in addition to the ancient national records, accommodation in fireproof chambers for all Scottish title deeds, entails, contracts and mortgages, and for general statistics, including those of births, deaths and marriages.

The Royal Institution, in the Doric style, surmounted by a colossal stone statue of Queen Victoria by Sir John Steell, formerly accommodated the board of trustees for manufactures and the board of fishery, the school of art, the Royal Society of Edinburgh (founded in 1783) and the Society of Antiquaries of Scotland (founded in 1780). In 1910 it was renamed and appropriated to the uses of the Royal Scottish Academy of Painting, Sculpture and Architecture, instituted in 1826, and incorporated

by royal charter in 1838, on the model of the Royal Academy in London. It is situated on the Mound close to the National Gallery (1850). These collections are especially rich in Raeburn's works and include also Alexander Nasmyth's portrait of Robert Burns and Gainsborough's "The Hon. Mrs. Graham." The National Portrait gallery and Museum of Antiquities are housed in Queen street. St. Giles's church, usually styled cathedral, restored (1872-83) by the liberality of Dr. William Chambers, the publisher, has many associations. The regent Moray, the marquess of Montrose, and Napier of Merchiston were buried within its walls and are commemorated by monuments, and among the memorial tablets is one to R. L. Stevenson. The choir (restored in 1873 by public subscription) is a fine example of 15th-century architecture, and the Gothic crown surmounting the central tower is a feature in many views of the city. Just outside the church in Parliament square, the supposed grave of John Knox is indicated by a stone set in the pavement bearing his initials, and in the pavement to the west a heart indicates the site of the old Tolbooth, which figures prominently in Scott's *Heart of Midlothian*. The original Tolbooth was completed in 1501, but a new one took its place in 1563-1564. At first occupied by the parliament and courts of justice, it served later as a prison, and was removed in 1817. Other churches having historical associations are Greyfriars church, which formerly occupied the two halves of one building but were united in 1937, Tron church, the scene of midnight hilarity at the new year, St. Cuthbert's church, St. Andrew's church in George street, whence set out, on a memorable day in 1843, that long procession of ministers and elders to Tanfield hall which ended in the founding of the Free Church, St. George's church in Charlotte square, a good example of the work of Robert Adam. The finest building belonging to the Scottish Episcopal Church is St. Mary's cathedral (1879). The mansion of East Coates (17th cent.), stands in the close, and is occupied by functionaries of the cathedral. The Catholic Apostolic church at the foot of Broughton street has a set of mural paintings by Mrs. Traquair. The Central hall at Tollcross testifies to Methodist energy. A house at the east end of the High street, said to have been John Knox's, is kept in repair, and contains articles of his furniture. The Canongate Tolbooth adjoins the parish church, in the burial ground of which is the tombstone raised by Burns to the memory of Robert Fergusson, here Dugald Stewart, Adam Smith and other men of note were buried. Almost opposite to it stands Moray house, from the balcony of which the 8th earl of Argyll watched Montrose led to execution (1650). The jail, a castellated structure on the black rock of Calton Hill, was demolished to make way for St. Andrew's house, the Scottish government building, opened in 1939. This was designed by T. S. Tait in a classical style and incorporates the south wall of the jail, which rises sheer from the cliffs, and the governor's house. Usher hall (1914), a large public hall in Lothian road was built on the bequest of £100,000 by Andrew Usher (1826-98). The Sheriff Court buildings stand on George IV bridge, and facing them is Andrew Carnegie's free library (1887-1889). At the corner of the High street and George IV bridge stand the County buildings. The *Scotsman*, the principal daily newspaper, is housed in an ornate office in North Bridge street. Ramsay gardens, a student's quarter fostered by Prof. Sir Patrick Geddes (1854-1932), grew out of the "goose-pie" house where Allan Ramsay lived. The Outlook tower on Castle Hill houses collections, partly illustrating town-planning, by Prof. Geddes. The old City Cross (restored at the cost of W. E. Gladstone) stands in the High street, adjoining St. Giles's. Several quaint groups of buildings have been carefully restored, such as the White Horse Close in the Canongate, the mass of alleys on the north side of the Lawnmarket, from Paterson's close to James's court have been connected, and here Lord Rosebery acquired and restored the 17th century dwelling called Lady Starr's house, which figures in the legend of *My Aunt Margaret's Mirror*. It is used as a branch museum. Another model restoration of a historic close is found in Kiddle's close, which contains a students' settlement. The changes in the Old Town (many of a drastic nature) have been carried out with due regard to the character of their environment.

Monuments—The National World War I memorial designed by Sir Robert Lorimer, is on the north side of Crown square, atop the castle rock. The exterior is rather severe, but the interior is of surpassing beauty. It was opened in 1927. An arched entrance porch, over which, in a deep recess, is a figure symbolic of immortality, leads to the Hall of Honour of 12 bays, containing memorials of the 12 Scottish infantry regiments and embellished with the arms of counties and burghs. Facing the entrance is an octagonal shrine with stained glass windows by Douglas Strachan and a bronze frieze by Morris Meredith Williams. The altar bearing the steel casket containing rolls of honour is a great block of marble resting on an outcrop of living rock rising through the floor. The Scott monument in East Princes street gardens was designed by George Meikle Kemp (1795-1844). A column surmounted by a colossal figure of Viscount Melville, Pitt's first lord of the admiralty, rises from the centre of St Andrews square. Burns's monument, in the style of a Greek temple, occupies a prominent position on the Regent road, on the southern brow of the lower terrace of Calton Hill. On Calton Hill is the national monument to the victory of Waterloo, originally intended to be a reproduction of the Parthenon. The plan was abandoned for lack of funds, after 12 out of the 24 Greek pillars had been erected. The Nelson monument, an elongated turreted structure, stands on the highest cliff of the hill. Close by is the monument to Dugald Stewart, a copy of the choragic monument of Lysicrates. Sir John Steell's equestrian statue of the duke of Wellington stands in front of the Register house, and in Princes street gardens are statues of Livingstone, Christopher North, Allan Ramsay, Adam Black and Sir J. Y. Simpson, and a memorial to the Scots Greys who fell in the Boer War. In George street are Chantry's figures of Pitt and George IV, and a statue of Dr Chalmers, the 5th duke of Buccleuch stands beside St Giles's. Charles II surveys the spot where Knox was burned, the reformer himself is in the quadrangle of New college. The statue of Sir David Brewster has been moved from the quadrangle of the university to the new buildings at West Mains, that of Dr William Chambers is in Chambers street, and Frederick, duke of York (1763-1827), and the 4th earl of Hopetoun are also commemorated. The Gladstone memorial in St Andrews square was unveiled in 1917. In the west part of Princes street gardens is the Scottish-American war memorial (1927), raised by U.S. subscriptions and designed by Professor R. T. MacKenzie of Philadelphia. It consists mainly of a kilted soldier in bronze.

Cemeteries—In Greyfriars' churchyard the Solemn League and Covenant was signed, and among its many monuments are the Martyrs' monument, recording the merits of the murdered covenanters, and the tomb of "Bluidy" Mackenzie. There are interesting memorials in the churchyards of St. Cuthbert's and the Canongate.

In the Calton burying-ground are the Roman tomb of David Hume, the obelisk raised in 1844 to the memory of Maurice Margarot, and the graves of Thomas Muir (1765-1798), Thomas Eysie Palmer (1747-1802), William Skirving and Joseph Gerald (1765-1796), the political martyrs convicted in 1793-94 for advocating parliamentary reform.

The Scottish dead in the American Civil War are commemorated in a monument bearing a life-sized figure of Abraham Lincoln and a freed slave.

Parks and Open Spaces—The older open spaces are Princes street gardens, Calton Hill, the Meadows and the Bruntsfield links. On the southern side is Blackford Hill with the Royal observatory. Harrison park is in the congested district of Fountainbridge. The park at Saughton hall was opened in 1905, for the western district of the city, and Hillend park on the Pentland slopes, in 1934. The Scottish Zoological park lies beyond Murrayfield, on the slopes of Corstorphine Hill. To the north of the Water of Leith lie Inverleith park, the Arboretum and the Royal Botanical garden which includes a herbarium, hot houses, and a museum of economic botany. Near it is the Stevenson Memorial house in Howard place. The most extensive open spaces surround Arthur's Seat (822 ft.). This is a basaltic hill, separated from the narrow valley in which lie the Canongate and Holyrood pal-

ace by Salisbury Crags. Adjoining Holyrood palace is the King's park. Facing the crags on the southwest are the spots familiar to readers of *The Heart of Midlothian*, where stood Jeanie Deans's cottage, and between the crags and Arthur's Seat lies Hunter's Bog, used as a shooting range. Near here too are three small lakes, Duddingston, Dunsappie and St. Margaret's, the last overlooked by the ruins of St. Anthony's chapel. On the Braed hills two golf links have been laid out and there are 140 ac. of playing fields.

Enviions—Leith (q.v.), the port of Edinburgh, was incorporated with the city in 1920. Newhaven, so called from the harbour constructed in the reign of James IV, had a shipbuilding yard of some repute in former times. The village has always been a fishing place of importance. To the west lies Granton, where the 5th duke of Buccleuch constructed a fine harbour. Still farther west lies the village of Cramond, at the mouth of the river Almond, where Roman remains have often been found. Lauriston castle is situated in the parish. Cramond Brig was the scene of one of the "roving" adventures of James V, when the life of the "Gude man of Ballencheig" was saved by Jack Howieson of the Braehead. Here are Craigcrook castle, where Lord Jeffrey spent many years, and Ravelston house, the home of the Keiths. To the south of the metropolis are Colinton, on the Water of Leith, and Currie, which was a Roman station and near which are Curriehill castle (held by the rebels against Queen Mary), the ruins of Lennox tower, and Riccarton. At Dalmahoy castle, near Ratho (pop. 1,672), the seat of the earl of Morton, are preserved the only extant copy of the Bible of the Scottish parliament and the original warrant for committing Queen Mary to Lochleven castle in Kinross shire. Craigmillar has a picturesque castle, part of which probably dates from the 12th century. Duddingston, once a quiet village, has become a centre of the distilling and brewing industries. Duddingston house was a seat of the duke of Abercorn. Restalrig, between Duddingston and Leith, was the home of the Logans, from whom the superiority of Leith was purchased in 1553 by the queen regent. Sir Robert Logan (d. 1606) was alleged to have been one of the Gowrie conspirators and to have arranged to imprison the king in Fast castle. This charge was made three years after his death, when his bones were exhumed for trial. He was found guilty of high treason and sentence of forfeiture was pronounced. A small chapel adjoining the old church covers the healing well of St. Triduana Liberton, a name that possibly recalls the previous existence of a leper's hospital, is situated on the rising ground south of Edinburgh, the parish church being a conspicuous landmark. Portobello is a popular seaside resort in the city, 3 mi. from the centre. Its beautiful sands are flanked by a promenade extending to Joppa. The town dates from the middle of the 18th century, when a cottage was built by a sailor and named Portobello in commemoration of Admiral Vernon's victory in 1739. The place does a considerable trade in the making of bricks, bottles, earthenware, tiles and paper and a large electric power station was opened in 1923. Joppa, which adjoins it, has salt works, but is chiefly residential. Lasswade, partly in the Pentlands, famous for its oatmeal, was often the summer resort of Edinburgh worthies. Melville castle and Auchendinny are in the neighbourhood. Most famous among the environs of Edinburgh are Rosslyn and Hawthornden. Rosslyn castle, on the beautifully wooded precipitous banks of the Esk, dates from the 12th century. The fine chapel, higher up the bank, founded in 1446 by William St. Clair, 3rd earl of Orkney, is believed to be the chapel of what was intended to be a large church, it suffered at the hands of revolutionary fanatics in 1688. The Gothic details, especially the wreathed "Prentice's pillar," are finely carved. The walk to Hawthornden, about 1½ mi. distant by the river-side, leads to the mansion of the Drummonds, on a lofty cliff falling sheer to the stream. The caverns in the sides of the precipice are said to have afforded Wallace and others refuge in time of trouble, but the old house is most memorable as the home of the poet William Drummond. The Pentland range contains many points of interest and beauty. Habbie's Howe is some 2 mi. from Carlisle, and Rulion Glen is noted as the field on which the Covenanters were defeated in 1666. Penicuik has paper mills and stone quarries.

ADMINISTRATION AND EDUCATION

Communications—Both L M S R (Princes St station) and L N E R (Waverley station) serve Edinburgh. Besides Leith, Granton and Grangemouth serve as passenger seaports for Edinburgh. Tramways connect all parts of the city, including Leith, Newhaven, Portobello and Joppa, and a suburban railway, starting from Waverley station, returns by way of Restalrig, Portobello, Duddingston, Newington, Morningside and Haymarket. In summer, steamers ply between Leith and Aberdeen and other pleasure resorts, and there is also a service to Alloa and Stirling.

Population—In 1801 the number of inhabitants was 67,288, in 1881 it was 228,357, in 1931 the figure was 439,010, and was estimated in 1938 at 469,448. The area is 50.6 sq mi, having been enlarged by successive extensions. In 1896 portions of the parishes of Liberton and Duddingston and the police burgh of Portobello were incorporated and in 1900 a further addition was made including Granton, Restalrig, and parts of South Leith and Duddingston. In 1920 Leith and the parishes of Corstorphine, Craigmond, Liberton and Colinton, including many villages to the south and west of the city, were incorporated with it.

Government—By the Redistribution act of 1918 the city with Musselburgh, was divided for parliamentary purposes into five divisions, each returning one member. Leith also returns a member. The town council, which has its headquarters in the Municipal buildings in the Royal exchange, consists of 70 members, a lord provost, 10 bailies, a dean of guild, a treasurer, a convener of trades, 10 judges of police, 9 of whom are councillors, and 46 other councillors. The corporation has acquired the gas-works, the transport undertakings, the electric lighting of the streets, and the water supply from the Pentlands.

May Meetings—During the establishment of Episcopacy in Scotland, Edinburgh was the seat of a bishop, and the collegiate church of St Giles became a cathedral. But the annual meeting of the General Assembly of the Church of Scotland at Edinburgh is now the public manifestation of the predominance of Presbyterianism as the national church. In May each year the sovereign appoints a representative as lord high commissioner to the General Assembly of the Established Church, who takes up his abode usually in the palace of Holyrood, and thence proceeds to the High Church, and so to the assembly hall on the Castle Hill when the lord provost and magistrates offer to him the keys of the city. The General Assembly of the United Free Church is usually held at the same time.

University—Edinburgh university, the youngest of the Scottish universities, was founded in 1583 by a royal charter, dated 1582, granted by James VI. In 1621 an act of the Scottish parliament accorded to the university all rights and privileges enjoyed by other universities in the kingdom, and these were renewed under fresh guarantees in the treaty of union between England and Scotland, and in the Act of Security. Important changes were made in the constitution by acts passed in 1858 and 1889. In the latter year, women were admitted to graduation and in 1916 three hostels for women were built. The students numbered 3,407 in 1942-43. As a corporation it consists of a chancellor, vice-chancellor, lord rector (elected by the students every three years), principal, professors, registered graduates and matriculated students. With St Andrews, Glasgow and Aberdeen it sends three members to parliament. While the college, as such, bears the name of the College of King James, or King's college, and James VI is spoken of as its founder, it really originated in the liberality of the citizens of Edinburgh. William Little of Craigmillar, and his brother Clement Little, advocate, along with James Lawson, the colleague and successor of John Knox, may justly be regarded as true founders. In 1580 Clement Little gave all his books, three hundred volumes, for the beginning of a library, and this was augmented by other valuable benefactions, one of the most interesting of which was the library of Drummond of Hawthornden. The older buildings of the university occupy the site of the ancient collegiate church of St Mary in the Fields (the "Kirk o' Field"), the scene of the murder of Darnley. The present Old college, designed by Robert Adam, dates from 1789. The Royal Scottish museum is structurally united to the univer-

sity and Minto House college and Heriot-Watt college are practically adjuncts of the university. The medical school stands in Teviot row, adjoining George square and the Meadows. The magnificent McEwan hall is used for academic and public functions. Closely associated with the medical school, and separated from it by the Middle Meadow Walk, is the Royal infirmary, designed by David Bryce, R S A (1803-1876), removed from Infirmary street. Its wards are lodged in a series of unroofed pavilions, and cover a large space of ground on the margin of the Meadows, from which, to make room for it, George Watson's college—the most important of the Merchant Company schools—was removed to a site farther west, while the Sick Children's hospital was moved to the southern side of the Meadows. George Watson's college was moved again (to Colinton road) in 1932 to make room for a further large extension, a maternity wing, to the Royal infirmary. This hospital is one of the largest in Great Britain. After 1930 chairs of psychology, geography and child life and health were established, also five chairs in the faculty of divinity and a chair of organization of industry and commerce. In 1919 the university acquired 115 ac of land at Liberton, and the new King's buildings of the university, containing chemical laboratories, etc., were opened at West Mains in 1924, and the department of animal genetics. In the same colony new laboratories for engineering and geology were opened in 1932. Considerable improvements were subsequently carried out in the Old college.

Scientific Institutions—The old observatory, on Calton Hill, overlooks the district at the head of Leith Walk. The City observatory stands close by, and on Blackford Hill is the newer building of the Royal observatory. The museum and lecture-rooms of the Royal College of Surgeons occupy a classical building in Nicolson street. The college is an ancient corporate body, with a charter of the year 1505, and exercises the powers of instructing in surgery and of giving degrees. Its extra-academic courses are recognized, under certain restrictions, by the University Court, as qualifying for the degree of doctor of medicine. The Royal College of Physicians is another learned body organized, with special privileges, by a charter of incorporation granted by Charles II in 1681. In their hall in Queen street are a valuable library and a museum of materia medica. But the college as such takes no part in the educational work of the university.

Other Educational Institutions—After the Disruption in 1843, and the formation of the Free Church, New college was founded in connection with it for training students in theology. After the amalgamation of the United Presbyterian and the Free Churches, under the designation of the United Free Church of Scotland, New college was utilized by both bodies. The Royal high school, the burgh school *par excellence*, is an ancient foundation, and the Grecian buildings (1829) on the south of Calton Hill, are its third habitation. Edinburgh academy was opened in 1825. Fettes college and Merchiston Castle school are organized on the model of the great English public schools. For many generations the charitable foundations for the teaching and training of youth were a conspicuous feature in the economy of the city. Foremost among them was the hospital founded for the maintenance and teaching of poor fatherless sons of freemen by George Heriot—the "Jingling George" of Scott's *Fortunes of Nigel*—the goldsmith and banker of James VI. The quadrangular building in Lauriston, sometimes ascribed to Inigo Jones, is one of the noblest in the city. Even earlier than Heriot's hospital was the Merchant Maiden hospital, founded in 1605, which gave to the daughters of merchants similar advantages to those which Heriot's secured for burgesses' sons. In 1738 George Watson's hospital for boys was founded, then followed the Trades' Maiden hospital for burgesses' daughters, John Watson's, Daniel Stewart's, the Orphans', Gillespie's, Donaldson's hospitals, and other institutions founded by successful merchants of the city, in which poor children of various classes were lodged, boarded and educated. The Merchant Maiden, George Watson and Daniel Stewart hospitals were converted to day schools in 1870 and called colleges, the name of the first being changed to Edinburgh Ladies' college. In 1871 a fourth school was opened under the name George Watson's Ladies' college. All four are administered by the Edinburgh

Merchant company education board. As the New Town expanded, the Heriot Trust—whose revenues were greatly benefited thereby—erected day schools in different districts, in which children received a free education, and, in cases of extreme poverty, a money grant towards maintenance. Public opinion as to the "hospital" system of board and education, however, underwent a revolutionary change after the Education act of 1872 introduced school boards. The governing body was reconstituted in 1885, and the income of the trust was applied for the upkeep of a day school at Heriot's hospital, and of the Heriot Watt college as a technical school, and for the provision of scholarships here and elsewhere. The college is affiliated to the university. The Church of Scotland has a training college, there is a large training college for teachers in Holyrood road, and a Roman Catholic college (1920) in Colinton road.

Besides the Royal infirmary there are a considerable number of more or less specialized institutions, two of the most important being situated at Craiglockhart. Throgmorton hospital, the oldest charity in the city, no longer exists as a hospital with resident pensioners, the trustees disburse annually pensions to certain poor burghesses and their wives and children, and the trust controlling the benevolent branch of the Gillespie hospital endowment is similarly administered.

Industries—Edinburgh is residential rather than manufacturing or commercial, but from 1507, when Walter Chapman set up the first press, to the present day, printing has enjoyed a career of almost continuous vitality. Publishing, on the other hand, has drifted away, only a few leading houses—such as those of Blackwood, Chambers and Nelson—still making the city their headquarters. Mapmakers, typefounders, bookbinders and lithographers all contribute their share to the prosperity of the city. Brewing is a strong industry, Edinburgh ale being proverbially good. The manufactures of paper machinery, gas and water meters, iron and wire fencing, indiarubber goods, etc., are important, and mention can be made of biscuit and confectionery making, whisky blending and the arts and crafts associated with furniture work. Stone quarrying is carried on, but the vast quarry at Craigleith, from which the stone for much of the New Town was obtained, was abandoned. Owing to the great changes effected during the latter part of the 19th century, some of the old markets were demolished and the system of centralizing trade was not wholly revived. The Waverley market deals in vegetables and fruit and is used for meetings and concerts. Slaughter-houses, cattle markets and grain markets were opened at Gorgie in 1910, thus obviating the driving of flocks and herds through the streets.

HISTORY

A fort or camp set up on the rock on which Edinburgh castle now stands was probably the nucleus around which, in prehistoric time, grew a considerable village. Under the protection of the hill fort, a settlement was established on the ridge running down to the valley at the foot of Salisbury Crags, and another hamlet, according to William Maitland (1693-1757), the earliest historian of Edinburgh, was founded in the area at the north-western base of the rock, a district that afterwards became the parish of St. Cuthbert, the oldest in the city. The Romans occupied the country for more than three hundred years. When they withdrew, the British tribes reasserted their sway. The southern Picts ultimately subdued the Britons, and the castle became their chief stronghold until they were overthrown in 617 (or 629) by the Saxons under Edwin, king of Northumbria from whom the name of Edinburgh is derived. Simeon of Durham (854) calls it *Edin-burgh*, and includes the church of St. Cuthbert within the bishopric of Lindisfarne. Its Gaelic name was *Dunedin*. In the 16th century the latinized form *Edina* was invented. Long after Edwin's conquest the lowland continued to be a debatable territory held by uncertain tenure but at length it was to a large extent settled anew by Anglo-Saxon and Norman colonists under Malcolm Canmore and his sons.

In the reign of Malcolm III (anmore the castle included the king's palace. There his queen, Margaret, grandmother of Edward the Confessor, died in 1093. It continued to be a royal residence dur-

ing the reigns of her three sons, and hence the first rapid growth of the upper town may be referred to the 12th century. The parish church of St. Giles is believed to have been founded in the reign of Alexander I, about 1110, and the Norman keep of the castle, built by his younger brother, David I, continued to be known as David's Tower till its destruction in the siege of 1572. Soon after his accession to the Scottish throne David I founded the abbey of Holyrood (1128), which from an early date received the court as its guests. But the royal palace continued for centuries to be within the fortress, and there both the Celtic and Stuart kings frequently resided. Edinburgh was long an exposed frontier town within a territory only ceded to Malcolm II about 1020, and even under the earlier Stuart kings it was still regarded as a border stronghold. Hence, though the village of Canongate grew up beside the abbey of David I, and Edinburgh was a place of sufficient importance to be reckoned one of the four principal burghs as a judicatory for all commercial matters, nevertheless, even so late as 1450, when it became for the first time a walled town, it did not extend beyond the upper part of the ridge which slopes eastwards from the castle. So long, however, as its walls formed the boundary, and space therefore was limited, the citizens had to provide house-room by building dwellings of many stories. These tall tenements on both sides of what is now High Street and Canongate are still prominent in the Old Town. The streets were mostly very narrow, the main street from the castle to Holyrood palace and the Cowgate alone permitting the passage of wheeled carriages. In the narrow "wynds" the nobility and gentry paid their visits in sedan chairs.

The other three royal burghs associated with Edinburgh were Stirling, Roxburgh and Berwick, and their enactments form the earliest existing collected body of Scots law. The determination of Edinburgh as the national capital, and as the most frequent scene of parliamentary assemblies, dates from the death of James I in 1436. Of the 13 parliaments summoned by that sovereign, only one, the last, was held at Edinburgh, but his assassination in the Blackfriars' monastery at Perth led to the transfer of the court and capital from the Tay to the Forth. The coronation of James II was celebrated in Holyrood abbey instead of at Scone, and the widowed queen took up her residence, with the young king, in the castle. Notwithstanding the favour shown for Stirling as a royal residence in the following reign, every one of the parliaments of James III was held at Edinburgh. James II conferred on the city various privileges relating to the holding of fairs and markets, and the levying of customs, and by a royal charter of 1452 he gave it pre-eminence over the other burghs. Further immunities and privileges were granted by James III, and by a precept of 1482, known as the Golden Charter, he bestowed on the provost and magistrates the hereditary office of sheriff, with power to hold courts, to levy fines, and to impose duties on all merchandise landed at the port of Leith. Those privileges were renewed and extended by various sovereigns, and especially by a general charter granted by James VI in 1603.

James III was a great builder, and, in the prosperous era which followed his son's accession to the throne, the town reached the open valley to the south, with the Cowgate as its chief thoroughfare. After Flodden the citizens hastened to construct a second line of wall, enclosing the Cowgate and the heights beyond, since occupied by Greyfriars church and Heriot's hospital, but still excluding the Canongate, as pertaining to the abbey of Holyrood. In the 16th century the movements connected with John Knox and Mary, queen of Scots, caused much activity at Edinburgh castle. With the departure, however, of the sixth James to fill the English throne in 1603 the town lost its pre-eminence for a long period. Matters were not bettered by the Act of Union signed in a cellar in High Street in 1707 amidst the execrations of the people and it was not till the hopes of the Jacobites were blasted at Culloden (1746) that the townfolk began to accept the inevitable. This epoch, when grass grew even in the High Street, long lingered in the people's memory as the "dark age."

By the accession of George III (1760) Edinburgh showed signs of revived enterprise. In 1763 the first North bridge, connecting the Old Town with the sloping ground on which afterwards stood

the Register house and the theatre in Shakespeare square, was opened, a little later the Nor' Loch was partially drained, and the bridging of the Cowgate in 1785 encouraged expansion southwards. Toward the end of the 18th century the New Town began to take shape on the grand, if formal, lines planned by James Craig (d 1795) and the erection of Regent bridge in Waterloo place (1819) gave access to Calton hill. The creation of Princes street led to further improvement. The earth and debris from the excavation of the sites for the houses in this and adjoining streets had been "dumped" in the centre of the diamed Nor' Loch. This unsightly mass of rubbish lay for a while as an eyesore, until it was converted into a broad way joining the new road at Hanover street with the Old Town at the Lawnmarket. Upon this street, which received the title of the Mound, were erected the National gallery and the Royal Institution.

Speaking generally, the New Town was resorted to by professional men—lawyers, doctors and artists—and in its principal streets are found the head offices of the leading banks and insurance offices. Expansion of the city has been southward—from Liberton, and south from Morningside to the Braid hills and the lower slopes of the Pentlands. In addition, much slum clearance and rehousing were carried out and many historic buildings were cleaned and restored.

EDINBURGSHIRE see MIDLOTHIAN

EDISON, THOMAS ALVA (1847-1931), U.S. inventor, born at Milan, O., Feb. 11, 1847, of Dutch ancestry on his father's side and Scottish on his mother's.

Edison's education was limited to three months in the public school of Port Huron, Mich. At 12 he became a railroad newsboy and after 15 earned his living as a telegraph operator in various cities, always studying and experimenting in his spare time. In 1868 he took out his first patent for an electrical vote recorder. During the next few years he devised stock tickers, duplex, quadruplex and automatic telegraph systems and the electric pen, which developed into the mimeograph, for the multiplication of typewriting. His invention (1877-78) of the carbon transmitter, in which compressed lamp-black buttons were used to obtain the necessary variable resistance in the circuit, marked a real advance in the art of telephony and aided materially in bringing the Bell telephone into practical use.

Most modern inventions result from the contributions of many minds, and it is often difficult for the courts to determine priority, but when Edison made application in 1877 for a "phonograph or speaking machine," the U.S. patent office could discover no previous record of the sort. The original model, costing \$18, was a cylinder covered with tinfoil and turned with a hand crank. Ten years afterward he developed a motor-driven machine with cylindrical wax records which speedily became popular. Later he invented a disk form reproducing with a diamond point for music, and the "Ediphone" for office dicta-

tion at Orange, N.J., Edison had been necessarily engaged in various forms of invention for more than 60 years and had taken out 1,033 patents up to April 1918. He died Oct. 18, 1931.

EDMONTON, a municipal and parliamentary borough of Middlesex, Eng., $7\frac{1}{2}$ mi. N of London bridge, with four stations on the Eastern Region railway system. Pop. (1951) 104,244. Area 6.09 sq. mi. Edmonton, consisting of Upper and Lower Edmonton, lies along the Old North road between Tottenham and Enfield, with the river Lea for its eastern boundary. It has grown very rapidly as an industrial area because of its numerous factories, including gas meter and gas stove works. Market gardening is also carried on there. The Church of All Saints, extensively restored, retains Perpendicular and earlier portions and some braves of interest, in the churchyard is the memorial of Charles Lamb, who lived and died (1834) at Edmonton, and his sister, William Cowper and John Keats were also residents, and the Bell inn is famed through Cowper's poem *John Gilpin*. Open spaces in Edmonton include Pymmes park (53 ac) and others. Among buildings are the town hall and public libraries, a technical institute (1912-13), 1 attorney's school (1924) and the county school (1911). Edmonton was incorporated in 1937 and returns one member to parliament.

have their counterpart in the line to Grande Prairie and the Peace river settlements, and that to the navigable Athabasca river at Ft. McMurray. Precipitation is heavier at Edmonton than in southern Alberta, and it is the centre of an important mixed farming area, extending as far north as the Peace river country. Both the provincial parliament buildings and the University of Alberta are situated there, the latter including departments in arts, agriculture, medicine and mining. The city is the centre of an important coal mining district but, for domestic use, the prevalent fuel is natural gas supplied from the immense deposits in the Viking, Kinsella and Fabyan fields to the east. With the rapid increase in the city's population, and that of its vast hinterland, manufacturing developed to a marked degree, particularly in packing plants, which reached the largest output of any city in Canada.

Adjacent to Edmonton on the Athabasca river at Ft. McMurray are large tar sand deposits. Industries include milling, lumbering, furniture and bedding, men's and women's garments, egg powdering plant, cereals and biscuits, oil refining. It is a large distributing centre both for the surrounding agricultural area and the extensive mining developments to the north, where the range of ore discoveries is remarkable, including precious metals and radium. The mid 20th century discoveries of oil in near-by areas, in quantities rivaling Turner valley, created a great boom. Several railways radiate from this city, and two transcontinental lines, together with lines serving the north country, including the Alaska highway. The city owns all its utilities including the production and distribution of electricity, waterworks, street railway and telephone systems. Edmonton with its strategic location on the great circle route to the orient has long been to the forefront in the matter of aviation, and was the first city in Canada to establish a municipal airport. Flights operate daily in every direction, including Alaska, Northwest Territories, transcontinental and the U.S. With the advent of World War II and the completion of the Alaska highway and other large northern projects, air traffic stepped up greatly.

EDMUND, SAINT [EDMUND RICHY] (c. 1175-1240), English saint and archbishop of Canterbury, was born at Abingdon, near Oxford. His father was a merchant who retired, with his wife's

consent, to the monastery of Eynsham, leaving in her hands the education of their family. Edmund began his education in a grammar school at Oxford, and at the age of twelve took a vow of perpetual chastity in the Virgin's church at Oxford. After graduating at Paris, for six years he lectured in the liberal arts, partly in Paris and partly in Oxford where he was the first to lecture on Aristotle. He then returned to Paris for his theological studies. He again lectured at Oxford on theology until c. 1222 when he accepted the treasurership of Salisbury cathedral. Little is known of his life for the next ten years. But he attracted the notice of the Roman court, and was appointed in 1227 to preach the crusade in England.

In 1233 he was elected archbishop of Canterbury at the express suggestion of Gregory IX, after the monks of Canterbury had in vain suggested three other candidates for the pope's approval. Edmund at once leaped into prominence by the outspoken manner in which he rebuked the king for following the advice of foreign favourites. In common with the baronial opposition he treated Henry III as responsible for the tragic fate of Richard Marshal, earl of Pembroke, and threatened the king with excommunication. The king bowed before the storm, dismissed the foreign counselors, made peace with Marshal's adherents, and was publicly reconciled with the barons. But it was with the object of emancipating himself from Edmund's control that the king asked the pope to send him a legate (1236). On the arrival of Cardinal Otho (1237) the archbishop found himself thwarted at every point. The marriage between Simon de Montfort and the Princess Eleanor, which Edmund had pronounced invalid, was ratified at Rome upon appeal. The king and legate upheld the monks of Canterbury in their opposition to the archbishop's authority. On all public occasions the legate took precedence of the archbishop. By the advice of his suffragans Edmund laid a protest before the king, and excommunicated in general terms all who had infringed the liberties of Canterbury. These measures led to no result, and after the papal encroachments of 1240, when the English clergy were required to pay a subsidy of a fifth for the war against Frederick II, and simultaneously three hundred Romans were "provided" with English benefices in return for their political services to the Holy See, Edmund withdrew to Pontigny. The state of his health drove him later to Soissy (near Provins), where he died on Nov. 16, 1240.

His canonization was at once demanded by his admirers, and only delayed (till 1247) through the opposition of Henry III. Edmund is one of the most saintly and attractive figures of the English church. As archbishop he showed no great capacity, but the purity of his motives and the loftiness of his ideals commanded universal respect. It was his misfortune to be placed at the head of the national hierarchy in a crisis for which he had not been prepared by practical experience.

Edmund's *Le Merue de Sainte Eglise* was last edited by H. W. Robbins (Lewisburg, 1925). See the life printed by Martene and Durand in the *Thesaurus novus anecdotorum* (1717). Other lives exist in ms. at the Brit. Museum, in Cambridge univ. library and in that of St. John's college, Cambridge. The last named is printed by W. Wallace in his *Life of St. Edmund* (1893). See also B. Ward, *St. Edmund* (1903), Baroness Paravicini, *St. Edmund of Abingdon* (1898), and the *Eng. Hist. Review*, xxxi.

EDMUND, king of East Angles (c. 840-870), succeeded to the East Anglian throne in 855 while yet a boy. According to tradition he was born at Nuremberg, and was the son of King Alkmund and Queen Scilvare. Offa, king of the East Angles, visited Alkmund on his way to the Holy Land, and adopted Edmund as his heir. Edmund succeeded him in 855, landing at Hunstanton. His coronation took place in the next year at "Burna" (i.e., probably Bures St. Mary, Suffolk), which was then the royal capital.

Of the life of St. Edmund during the next 14 years we know nothing. In 870 the Danes, who had been wintering at York, marched through Mercia into East Angles and took up their quarters at Thetford. Edmund engaged them fiercely in battle at Home, but the Danes under their leaders, Ubba and Ingvar, were victorious. The king himself was slain, whether on the actual field of battle or in later martyrdom is not certain, but

the version of the story which makes him fall a martyr to the Danish arrows when he had refused to renounce his faith or hold his kingdom as a vassal from the heathen overlords, may be true. The king's body was ultimately interred at Beadonsworth, the modern Bury St. Edmunds. The shrine of Edmund soon became one of the most famous in England, and the reputation of the saint was European. The date of his canonization is unknown, but churches dedicated to his memory are found all over England.

See *Aver's Life of Alfred* ed. W. H. Stevenson, *Annals of St. Neots*, *Saxon Chronicle*, *Memorials of St. Edmund's Abbey* (Rolls Series), including the *Passio Sancti Edmundi* of Abbo of Fleury, and the *Corolla Sancti Edmundi*, ed. Lord Francis Hervey (1907).

EDMUND I, king of the English (d. 946), was the son of Eadwig, third wife of Edward the Elder, and half brother to his predecessor Aethelstan. He succeeded to the throne in 940, but had already played an active part in the previous reign, and fought with Aethelstan in the great battle of Brunanburh.

In the first year of Edmund's reign Olaf or Anlaf Sihtricsson, called Cuaran, who had crossed from Ireland, had been chosen king by the Northumbrians. Anlaf took York, besieged Northampton and destroyed Tamworth, but was met by Edmund at Leicester. A peaceful settlement was made by the good offices of Odo of Canterbury and Wulfstan of York. Simeon of Durham's statement that the kingdom was now divided between Anlaf and Edmund and his story of the reconquest of Northern Mercia by Edmund probably refer to the compact with Anlaf, made as a result of the campaign. All Mercia south of a line from Dore (near Sheffield), through Whitwell to the Humber, was now in Edmund's hands, and the five Danish boroughs, which had for some time been exposed to raids from the Norwegian kings of Northumbria, were now freed from that fear. The peace was confirmed by the baptism of King Anlaf and Raegenald, Edmund standing as sponsor, but in 944 or 945 the peace was broken and Edmund expelled Anlaf and Raegenald from Northumbria.

In 945 Edmund ravaged Strathclyde, and entrusted it to Malcolm, king of Scotland, "on condition that he should be his fellow worker by sea and land," the object of this policy being apparently to detach the king of Scots from any possible confederacy such as had been formed in 937.

On May 26, 946, Edmund's brief but energetic reign came to a tragic conclusion when he was stabbed at the royal villa of Pucklechurch, in Gloucestershire, by an exiled robber named Llofa. Edmund, the "deed doer" as the chronicle calls him, "Edmundus magnificus" as Florence of Worcester describes him, perhaps translating the Saxon epithet, was buried at Glastonbury, an abbey which he had entrusted in 943 to the famous Dunstan.

Edmund was twice married, first to Aelfgifu, the mother of Eadwig and Edgar, secondly to Aethelflaed "aet Damerfrane" (i.e., of Damerham, Co. Wilts). Aelfgifu died in 944, according to Ethelwerd.

See *The Anglo-Saxon Chronicle* (ed. Plummer, 1892-99), *Simeon of Durham* (Rolls Series), *A. S. Laws*, ed. Liebermann, pp. 184-191, Birch, *Cartularium Saxonicum*, Nos. 745-817, *Dictionary of National Biography*, v, v.

EDMUND or EADMUND (c. 980-1016), called IRONSIDE, king of the English, was the son of Aethelred II (the Unready) by his wife Emma, or Aelfgifu. When Canute invaded England in 1015, Edmund was betrayed and deserted by the ealdormen. Eadric, who went over to Canute, and Wessex submitted to the Danish king. Next year Canute and Eadric together harried Mercia, while Edmund with infinite difficulty gathered an army. His attack on the invaded districts of Northumbria was brought to an end by Canute's northward march, and he was forced to return to London. The death of Aethelred on April 23, 1016, was followed by a double election to the English crown. The citizens of London chose Edmund, the rest of the Witan meeting at Southampton elected Canute. In the warfare which ensued Edmund fought at the severest disadvantage, for his armies dispersed after every engagement. Canute besieged London, but the citizens successfully resisted all attacks. Edmund meanwhile received the submission of Wessex. At Pen in Somersetshire he engaged the Danes and defeated them. Canute now raised the siege of London and,

after being defeated by Edmund at Pen, came into conflict with him again at Sherston in Wiltshire. The battle was indecisive, but Canute left Edmund in possession of Wessex. Edmund hastened after him and relieved London, which Canute was besieging. He defeated the Danes at Brentford and at Otford, and drove them into Sheppey. He was now joined by Edric, with whom he followed the Danes into Essex, overtaking them at Assandun (or Ashington). In the battle which ensued Edric again played the traitor, and the English were routed. Edmund retired into Gloucestershire, whither he was followed by Canute. Edric and the Witan then persuaded Edmund to accept a reconciliation, which took place at Olney. The kingdom was divided—Canute taking the north, Edmund the south. Soon afterwards Edmund died (Nov. 30, 1016), probably from natural causes, though later historians hint at foul play.

EDMUND (CROUCHBACK), king of Sicily and earl of Lancaster (1245-96), was the second son of Henry III of England by Eleanor of Provence. At ten years of age Edmund was invested by Pope Alexander IV with the kingdom of Sicily (April 1255), the pecuniary obligations which Henry III undertook on his son's behalf were among the causes which led to the Provisions of Oxford and the Barons' War. Alexander annulled his grant in 1258, but still pressed Henry for the discharge of unpaid arrears of subsidies. In 1265, after Montfort's fall, Edmund received the earldom of Leicester, and two years later was created earl of Lancaster. He joined the crusade of his elder brother, the Lord Edward (1271-72), and supported him on his accession. In 1275, two years after the death of his first wife, Aveline de Foribus, Edmund married Blanche of Artois, the widow of Henry III of Navarre and Champagne. Although the county of Champagne was held by his wife in custody for her infant daughter, Joan, Edmund assumed the title "Count Palatine of Champagne and Brie." This he was compelled to renounce upon the marriage of Joan to Philip the Fair, the heir to the crown of France, but he retained the possession of his wife's dowlands in Champagne. He was employed by his brother as a mediator with Philip the Fair in 1293-94, but allowed himself to be tricked out of possession of the duchy, which Philip's court declared forfeit. He was appointed lieutenant of Gascony in 1296 but died in the same year, leaving a son, Thomas, to succeed him in his English possessions.

See W. E. Rhodes, "Edmund, Earl of Lancaster," *English Historical Review*, vol. x (London, 1895).

EDMUNDS, GEORGE FRANKLIN (1828-1919), U.S. lawyer and political leader, was born in Richmond, Va., on Feb. 1, 1828. He began the practice of law in 1849. He was a member of the Vermont house of representatives (1854-59), acting for the last two years as speaker, and was a member and president *pro tem* of the state senate (1861-62). In 1866 he became a member, as a Republican, of the U.S. senate, where he remained until 1891, when he resigned in order to have more time for the practice of his profession. He took an active part in the attempt to impeach Pres. Andrew Johnson. He was influential in establishing the electoral commission to decide the disputed presidential election of 1876, and became one of the commissioners. In the national Republican nominating conventions of 1880 and 1884 he was a candidate for the presidential nomination. From 1884 to 1885 he was president *pro tem* of the senate. As senator he was conspicuous for his cause of his legal and parliamentary attainments, his industry and his liberal opinions. He was the author of the so-called Edmunds act (1882) for the suppression of polygamy in Utah, and of the antitrust law of 1890, popularly known as the Sherman act. He died in Pasadena, Cal., on Feb. 27, 1919.

EDO, a group of African tribes closely related by language and culture, inhabiting a large part of the region to the west of the lower Niger. The Edo dialects are more closely allied to Ewe (especially the Popo dialect) than to the intervening Yoruba. Of the four main Edo speaking tribes—the Urhobo (Sobo) to the south, the Bini in the centre, the Ishan (Esa) to the east and the Kukuruks (with numerous subtribes) to the north—the Bini, though numerically the smallest, are by far the most important, and indeed were formerly one of the most powerful of all African tribes, having the only great empire centred in the forest zone (see BENIN). The art, especially the bronzework, of Benin, which was at its apogee before the arrival of the first Portuguese in West Africa, is the most famous and sought after, but neither the most refined nor the most creative, of all African art styles. The na-

ture of the other Edo tribes is little known by comparison. Edo culture, though strongly *animist*, has adopted many Yoruba traits including some elements in their religion, such as the worship of the sea god Olokun, said to have been introduced from Yorubaland in the 14th century.

See H. Ling Roth, *Great Benin* (London, 1903); P. A. Talbot, *The Peoples of Southern Nigeria*, 4 vol. (Oxford, New York, 1926); J. W. Hubbard, *The Sobo of the Niger Delta* (Zaria, 1952); Chief J. V. Egharevba, *A Short History of Benin* (Lagos, 1953). (W. B. Fu.)

EDOM (Greek *Idumaea*), the district situated to the south of Palestine, between the Dead sea and the Gulf of 'Akaba, the inhabitants of which were regarded by the Israelites as a "brother" people (see ESAU). On the east it touched Moab, the tribes of the great desert and the northern part of Arabia, on the west its boundaries were determined by the Sinaiic peninsula, Egypt and Israel. Both Kadesh and Mt. Hor (perhaps Jebel Madera) are represented as lying on its border (Num. xx 16, 22), and the modern Wadi el-Yikreh, in which the "Scorpion pass" was probably situated (Judg. 1 36, Num. xxxiv 4), may have marked its limits from Jebel Madera northwest toward the southern extremity of the Dead sea. The precise borders, however, must have been determined by political conditions by the relations between Edom and its neighbours, Judah, the Philistine states, Moab and the restless desert tribes with which Edom was always very closely allied.

The early history of Edom is obscure, Egyptian references to it are few and do not give much light regarding the early inhabitants. In the early records of the Pentateuch, the country is often referred to by the name of Seir, the general name for the whole range of mountains on the east side of the Jordan-Arabia depression south of the Dead sea. These mountains were occupied by a cave dwelling aboriginal race, the Horites. According to Old Testament tradition, the Edomites were a new race who drove out the Horites from Mt. Seir.

The occupants of Edom during practically the whole period of Biblical history were the Bedouin tribes which claimed descent through Esau from Abraham, and were acknowledged by the Israelites (Deut. xxiii 7) as kin. Among the peculiarities of the Edomites was government by certain officials known as *dukes*, which the English versions translate "dukes." The now naturalized word "sheikhs" would be the exact rendering. In addition to this Bedouin organization there was the curious institution of an elective monarchy. A list of eight kings, who reigned before the Israelite monarchy is preserved in Gen. xxxvi. Saul the first king of Israel, conquered Edom (1 Sam. xiv 47), as did David, the second king.

After David's conquest, the Edomite prince Hadad escaped to Egypt, where he remained until the death of David. If, as the narrative of Kings xi implies, he became a troublesome adversary to King Solomon, nothing is known of his achievements, and if Solomon's trading-journeys from Ezon-geber were maintained, Edom must have been weak. Edom was under the rule of Jehoshaphat of Judah, who, with Israel held Ezon-geber (1 Kings xxii 47 sqq., 2 Chron. xx 35 sqq.). Some catastrophe befell the fleet, and shortly afterwards Jehoshaphat's son Jehoram had to face a revolt in which Edom and the men of Libnah (the Philistines) were concerned. It was about this period that Israel had conquered Moab, thrusting it farther south towards Edom, and the subsequent success of Moab in throwing off the yoke, and the unsuccessful attempt of Jehoram of Israel to regain the position, may show that Edom was also in alliance with Moab. In the time of Adad-nirari of Assyria (811-783 B.C.) Edom is mentioned as an independent tributary with Beth-Omri (Israel) and Palastu (Philistia). The absence of Judah is noteworthy. Amariah of Judah had gained a signal victory over Edom in the valley of Salt (2 Kings xiv 7), but after his defeat by Jehoshaphat of Israel there is a gap and the situation is obscure. Consequently it is uncertain whether Edom was the vassal of the next great Israelite king, Jeroboam II, or whether the Assyrian evidence for its independent position belongs to this later time. However, Uzziah, a contemporary of Jeroboam II, and one of the most successful of Judaean kings, overcame Edom and its natural allies (2 Chron. xxvi 6 sqq.) and at this stage Edomite history becomes more

prominent. It joined the great coalition in which Philistia and Israel were leagued against Assyria, and drove out the Judeans who had been in possession of Elath (2 Kings xvi 6). On the events that followed see *ARAZ*, *HEZKIAH*, *PHILISTINES*. In the middle of the 7th century both Edom and Moab suffered from the restlessness of the desert tribes, and later joined in the attempt made by Zedekiah of Judah to revolt against Nebuchadnezzar (Jer xxvii 3).

Edom in alliance with the tribes along the trade routes (Philistines, Moabites etc.) was responsible for many attacks upon Israel, carrying away prisoners as slaves for Garam and Tyre (Am i 6 seq. 9). As in ally or vassal Edom was in touch with the wealth of Arabia (Ezek xxvii 16, read "Edom" for "Aram") and Judah and Israel as well as Garam and Damascus enjoyed the fruits of its commerce. Edomite and allied tribes were famed for their wisdom (Ob 8 Jer viii 7 seq., Baruch ii 22), and besides the possibility of Arabian influence upon Israelite culture, the influence of Midian and related tribes is certain from the traditions of Moses and of his work (see *JETHRO*, *KENITES*, *MOSES*), and the Edomite district was a traditional home of Yahweh him self (Deut xxviii 2, Judg v 4, Hab iii 3). It should be added however, that the Edomite names and other evidence point to the cult of other gods.

In the last years before the fall of Jerusalem many of the Jews found a refuge in Edom (Jer xl 11), although other traditions throw another light upon the attitude of Edom during these disasters. It is said that Edomites burned the temple after the destruction of Jerusalem (1 Esd iv 45, cf v 50), and naturally the weak state of Palestine invited attacks from the outlying tribes, but the tone of certain late writings implies a preliminary period of, at least, neutrality (cf Deut ii 4 seq., Ezra vii 1 seq., the omission of Edom in xxiii 3, Neh xiii 1, and in Ezra ix 1—contrast 1 Esd viii 69). Edom is execrated for revengeful attacks upon the Jews, and its speedy destruction is foretold, but the passages appear to be later than the disaster of 586 B.C., and may even imply conditions after the restoration (Ob 10 seq., Ezek xxv 12-14, Jer xliii 7, Ps cxxxvii 7, Lam iv 21 seq., v 2 seq.). Even finally the constant westward pressure of the eastern Arabs forced the ancient Edomites across the Jordan Araba depression. With their name they migrated to the south of western Palestine. In 1 Maccabees v 65 they are at Hebron, and this is one of the first indications of the cis Jordanian Idumaea of Josephus and the Talmud. See, for the later history, *HEROD*, *Jews*.

Josephus used the name Idumaea as including not only Gabahtis, the original Mt. Seir, but also Amalekites, the land of Amalek, west of this, and Akrabatine, the ancient Acrababim, S.W. of the Dead Sea. Jerome describes Edom as extending from Beit Jibrin to Petra, and ascribes the cave graves at the former place to cave dwellers like the aboriginal Hittites. Ptolemy's account presents the last stage in which the name Edom is entirely restricted to the cis Jordanian district and the old trans Jordanian region is described as *ARABIA*.

L. in *Rev. d'Ét. juv.* (Jan 1906). For the history and culture of the latest period, see J. P. Peters and Th. Nöldeke, *Paenit. Tomba in the Necropolis of Myra* (1905), ch. i. (S. A. C. R. A. S. N. 10).

EDRED (*ÆDRD*), king of the English (d. 955), was the youngest son of Edward the Elder and his wife Ædifu. He succeeded his brother Edmund in the year 946 and received the formal submission of the Northumbrians and Scots. In the next year Ædifu went to Tan-burh in Yorkshire, where he received from Wulfstan, archbishop of York and the Northumbrian "witan" confirmation of their submission. Shortly after they threw their pledges to the winds and took the Norwegian Eric Bloodaxe, son of Harold Fairhair (Harald Harfagar), as their king. Ædred recklessly ravaged all Northumbria in revenge, burning Ripon during his march. On his return home Ædred's rear-guard was attacked at Casterford, and he once more turned to ravage Northumbria, which was only saved by its abandonment of Eric and by compensation made to Ædred. Archbishop Wulfstan seems to have been a centre of disaffection in the north and in 952 Ædred

caused him to be imprisoned in the castle of "Judnburh" while in the same year the king's revenge for the slaying of Abbot Eadelm, slew many of the citizens of Thetford. After the brief rule of Anlaf Cuaran in Northumbria, Eric was once more restored probably in 950 only to be expelled again in 953 or 954, when Ædred took the Northumbrian kingdom into his own hands. In the same year Wulfstan was liberated and appointed to the Mercurian bishopric of Dorchester. Ædred died on Nov. 23, 955 at Frome, in Somersetshire and was buried in the old minster at Winchester. During the whole of his life Ædred was troubled by all health, a fact which may help to explain some of the more passionate acts of violence attributed to him. The king was throughout his life on terms of personal intimacy with St. Dunstan, and his public policy was largely guided by that prelate and by his mother Ædifu. It is not known that Ædred married.

EDRIC (or **EADRIC**), **STREONA** (d. 1017) ealdorman of the Mercians, was a man of ignoble birth who was advanced to high dignity through the favour of the English king Aethelred II. In 1007 he became ealdorman of the Mercians and in 1009 married Aethelred's daughter Eadgyth. In the struggle between the English and the Danes he appears in the character of an arch traitor. When Aethelred in 1009 proposed a great attack on the Danes, Eadric dissuaded him from carrying it into effect. At the "witan" held in Oxford in 1015 Eadric had Sigerth and Morkere slain by treachery. In the same year Canute invaded England. Eadric, who had joined Edmund Ironside, subsequently quarrelled with him and went over to Canute. After the battle of Otford he returned to Edmund, but only to secure the utter defeat of the national cause by his treachery at the battle of Assandun. After Edmund's death Canute restored to Eadric the earldom of Mercia but in 1017, fearing further treachery, he had him slain.

EDUCATION, ARTICLES ON. The history of education from early times is treated in the main article *EDUCATION* HISTORY or

For the subject of curriculum see *SCHOOL*, and *CURRICULUM*. For other articles of a general and particular character see *ADULT EDUCATION*, *ATYPICAL CHILDREN*, *BLIND*, *TRAINING* and *WELFARE OF THE*, *CLASSICAL EDUCATION*, *COEDUCATION*, *COMMERCIAL EDUCATION*, *DEAF* and *HARD OF HEARING*, *EDUCATION OF THE*, *ELEMENTARY EDUCATION*, *EXAMINATIONS*, *KINDERGARTEN*, *MENTAL DEFICIENCY*, *MONTESSORI SYSTEM*, *NURSERY SCHOOLS*, *PHYSICAL EDUCATION*, *POLYTECHNIC*, *SECONDARY EDUCATION*, *TEACHERS*, *TRAINING OF*, *TECHNICAL EDUCATION*, *UNIVERSITIES*, etc. For specialized education, see *AGRICULTURAL EDUCATION*, *JOURNALISM*, *SCHOOLS OF*, *LITERARY EDUCATION*, *MEDICAL EDUCATION*, etc.

EDUCATION, HISTORY OF. In ancient Greece the supremacy of the state was generally unquestioned and especially in the earlier times, the good man was identified with the good citizen. The highest life as one of cultured leisure in which the energies were inwardly concentrated on the pursuit of knowledge for its own sake. But this life was only for the select few; for the undisciplined mass the fulfilment by each of the duties of his station remained the measure of a worthy life. To which there fore who devoted their lives to the highest culture, the essential preliminary condition was the existence of such a state as would form the most favourable environment for their cultured life. Thus Greek thought was saturated with the conception of life as essentially a set of relations between the individual and the city state of which he formed an integral part. The first aim of education was to train the young citizens. (For the evolution of the school from early times see *SCHOOLS*, *ANCIENT*.)

Each state, however, had its special character, and to this character the education given in it had to conform if it were to be an effective instrument for training the citizens. From these fundamental conceptions flowed the demands of Plato and Aristotle that education should be regulated in all its details by the state authority, should be compulsory for all free citizens, and

should be uniform—at any rate in its earlier stages—for all. In the *Republic* and the *Laws*, Plato shows to what extreme lengths theory may go when it neglects to take account of some of the most pertinent facts of life. For the guardian citizens of the ideal state family life and family ties are abolished. Aristotle, indeed did not go to these extreme lengths, he allowed the family to remain, but he seems to have regarded it as likely to affect children more for evil than for good. Neither philosopher, however was at variance with the accepted Greek theory on the subject although the actual practice of Greek states departed and often widely, from this ideal, for, especially in later centuries, the Greek always tended to live his own life. The nearest approach to the theory was found in Sparta, where the end of the state as a military organization was kept steadily in view, and where, after early childhood, the young citizens were trained directly by the state in a kind of barrack life—the boys to become warriors, the girls the mothers of warriors. It was this feature of Spartan education, together with the rude simplicity of life it enforced which attracted Plato, and, to a less extent, Aristotle. In Athens there had of old been state laws insisting on the attendance of the children of the free citizens at school, and in some degree, regulating the schools themselves. But at the time of Plato these had fallen into desuetude, and the state directly concerned itself only with the training of the *ephebi* (ἐφῆβι) in intellectual and physical pursuits. For children and youths under the *ephebic* age there was no practical regulation of schools or palaestra by the state. Yet there is no doubt that the education really given was in conformity with Athenian ideals of culture and life, and that it was generally received by the children of free citizens, though of course the sons of the wealthy, then as now, could and did continue their attendance at school to a later age than their poorer brethren. The education of girls was essentially a domestic training. What Plato and Aristotle, with the theorist's love of official systematic regulation, regarded as the greatest defect of Athenian education was in reality its strongest point. In practice, the harmony between individual liberty and social claims was much more nearly attained under a system of free working out of common thoughts and ideals than would have been the case under one of the irresistible imposition from without of a rigid mould.

The instruments of education everywhere found to be in harmony with the Greek conception of life and culture were essentially twofold—music (μουσική), or literary and artistic culture for the mind, and systematic gymnastic (γυμναστική) for the body. Plato, in the *Republic*, shows that the latter, as well as the former, affects the character, and doubtless, though not formulated, this was generally more or less vaguely felt. But Greek gymnastic was really an individual training, and therefore made only indirectly for the aim of cultivating the social bonds of citizenship. The musical training was essentially in the national literature and music of Greece, and this could obviously be carried to very different lengths. The essential purpose throughout was the development of the character of a loyal citizen of Athens. As Athenian culture advanced, increasing attention was paid to intellectual studies, especially in the *ephebic* age, with a corresponding decrease of attention to merely physical pursuits, hence the complaints of such satirists as Aristophanes of a growing luxury, effeminacy and corruption of youths, complaints apparently based on a comparison of the worst features of the actual present with an idealized and imaginative picture of the virtues of the past. But a disintegrating force was already at work in the educational system of Greece which Plato and Aristotle vainly opposed, this was the rhetorical training of the Sophists. In a democratic city state the orator easily became a demagogue, and oratory was the readiest path to influence and power. Thus oratory opened the way to personal ambition, and young men who were moved by that passion eagerly attended the Sophist schools where their dominant motive was strengthened.

Further, the closer relations between the Greek states, both in nearer and farther Hellas, led naturally to the diminution of differences between civic ideals, and as a consequence, to a more cosmopolitan conception of higher education. This process was completed by the loss of political independence of the city states

under the Macedonian domination. Henceforth, higher education became purely intellectual and its relation to political and social life increasingly remote. The University of Athens was the outcome of a fusion of the private philosophical schools with the state organization for the training of the *ephebi*, and there were other such centres of higher culture, especially in after years at Alexandria where the contact of Greek thought with the religions and philosophies of Egypt and the east gave birth in time to the more or less mystical philosophies which culminated in Neo-platonism. But at Athens itself education became more and more a mere training in unreal rhetoric, until the dissolution of the university by Justinian (A.D. 529).

Ancient Rome—Thus when Rome conquered Greece, Greek education with which it came in contact was an education which had largely lost its lifespings. In the earlier centuries of the republic, Roman education was given entirely in family and public life. The father had unlimited power over his son's life and was open to public censure if he failed to train him in the ordinary moral, civic and religious duties. But it is doubtful if there were any schools, and it is certain there was no national literature to furnish an instrument of culture. A Roman boy learned to reverence the gods, to read to bear himself well in many exercises and to know enough of the laws of his country to regulate his conduct. This last he acquired directly by hearing his father decide the cases of his clients every morning in his hall. The rules of courtesy he learned similarly by accompanying his father to the social gatherings to which he was invited. Thus early Roman education was essentially practical, civic and moral, but its intellectual outlook was extremely narrow.

When a wider culture was imported from Greece, the instrument of education first introduced was Greek literature, much of which was soon translated into Latin. In time the schools of the *grammatici*, teaching grammar and literature, were supplemented by schools of rhetoric and philosophy, though the philosophy taught in them was itself little more than rhetorical declamation. These furnished the means of higher culture for those youths who did not study at Alexandria or Athens, and were also preparatory to studies at those universities. Under the empire the rhetorical schools were gradually organized into a state system. This widening of culture affected both boys and girls, the domestic education of the latter being supplemented by a study of literature. But it is the higher training in rhetoric which is especially characteristic of Hellenized Roman education.

The conception of a rhetorical culture is seen at its best in Quintilian's *Institutio oratoria*, the most systematic treatise on education produced by the ancient world. With Quintilian the ideal of an orator was a widely cultured, wise and honourable man. And at first the teaching of rhetoric undoubtedly made for higher and true culture. But with the autocracy, soon passing into tyranny, of the empire, rhetoric ceased to be a preparation for real life. Nor was there anything in the general conditions of society to counterbalance the ill effects of such an unreal education. Quintilian lamented that, even in his time, the old Roman family education by example was corrupted, and the moral degradation of later times, though it has doubtless been exaggerated, was certainly real and widespread. The religious revival of paganism which synchronized with the early centuries of Christianity does not appear to have effected any reform in life. Alexandria, the birthplace of Neoplatonism and the intellectual centre of the later empire, was also a very sink of moral obliquity.

Christianity and Pagan Education—It was into such a decaying civilization that Christianity brought new life. Of course, careful instruction in the Faith was given in catechetical schools, of which that at Alexandria was the most famous. But the question of the attitude of Christians toward the ordinary classical culture became of growing importance. The Greek fathers, especially Clement of Alexandria (150-217) and Origen (185-253), regarded Christianity as essentially the elimination of philosophy, to which the way must be found through liberal culture. Without a liberal education the Christian could live a life of faith and obedience but could not attain an intellectual understanding of the mysteries of the Faith. On the other hand,

Tertullian (160-240) was very suspicious of pagan culture, though he granted the necessity of employing it as a means of education yet he did so with regret. Many of the cultivated Christians of the 3rd and 4th centuries were little more than nominal adherents to the Faith, and the intercourse between Christian and pagan was often close and friendly. The general attitude of Christians toward the traditional education is evidenced by the protest raised against the edict of Julian, which forbade them to teach in the public schools. The ultimate outcome seems to be fairly expressed in the writings of St. Augustine (354-430) and St. Jerome (346-420), who held that literary and rhetorical culture is good so long as it is kept subservient to the Christian life.

In another way Greek philosophy exercised a formative influence over the culture of future ages, in the case of the Eastern Church through Neoplatonism, the last effort of paganism to attain a conception of life and of God. In the west, this formulation had to be translated into Latin, for Greek was no longer generally understood in Italy, and thus the juristic trend of Roman thought also became a factor in the exposition of Christian doctrine. This formulation of the Faith was one of the chief legacies the transition centuries passed on to the middle ages. Had classical culture been less formal than it was during the early centuries of Christianity the innate antagonism of the pagan and Christian views of life and character must have been so apparent that the education which prepared for the one could not have been accepted by the other. Thus the pagan ideal of life, especially as it had been developed in the individualistic ethics which had prevailed for more than six centuries as antithetical in essence to that of the Christian Church. The former was essentially an ethics of self reliance and self-control showing itself in moderation and proportion in all expressions of life. An essential feature in such a character was high-mindedness and a self respect which was of the nature of pride. On the contrary, Christian teaching exalted humility as one of the highest virtues, and regarded pride and self-confidence as the deadliest of sins. The highest state attainable by man was absorption in loving ecstasy in the mystic contemplation of God. The practical attempt to realize this gave rise to monasticism, with its minutely regulated life expressing unlimited obedience and the renunciation of private will at every moment. The monastic life was regarded as the nearest approach to the ideal which a Christian could make on earth. Naturally, as this conception gathered strength in generations nurtured in it, the value of classical culture became less and less apparent, and by the time of St. Gregory the Great (d. 604) the use of classical literature as a means of education was discouraged.

Of course, during these centuries, the gradual subjugation of the western empire by the barbarians had been powerfully operative in the obscuring of culture. Most of the public schools disappeared, and such light of learning as was kept burning in the monasteries was mainly confined to monks and novices. Though the barbarians absorbed the old culture in various degrees of perfection, yet the four centuries following the death of Augustine were plunged in intellectual darkness, relieved by transitory gleams of light in Britain and by a more enduring flame in Ireland. The utmost that could be done was to preserve to some extent the heritage of the past. This, indeed, was essentially the work of men such as Boethius, Cassiodorus, Isidore and Bede.

Modification of Latin.—During these same centuries another process had been advancing with accelerating steps. This was the modification of the Latin language. Thus with Christian civilization the modification of the past gradually gave way to the evolution of a new and living Latin which showed itself more and more regardless of classical models. The Christian Latin was a real living instrument of expression, which conformed closely in its structure to the mode of thought and expression of actual life. It is the Latin in which St. Jerome wrote the Vulgate. But with the obscuring of culture during the barbarian invasions this current Latin became more and more obnoxious of every such elements of form as grammatical inflections and concord.

It was to the reformation of this corrupt Latin by a return to classical models and to the more general spread of culture, especially among clergy and nobles, that the Carolingian revival addressed itself. The movement, essentially practical and conservative was directed by Alcuin (735-804), who was Charlemagne's educational adviser and chief executive officer in scholastic matters. Its most valuable outcome was the establishment of the palace school, and of bishops' schools and monastic schools throughout the empire. Thus, the educational system north of the Alps was pre-eminently ecclesiastical in its organization and profoundly religious in its aims. For two centuries the new intellectual life was obscured by the troubled times which followed the death of Charlemagne, but the learning which the Carolingian revival had restored was preserved here and there in cathedral and monastic schools, and the sequence of well educated ecclesiastics was never altogether interrupted.

Mediaeval Curriculum.—The scope of that learning was comprised within the seven liberal arts and philosophy, on the secular side, together with some dogmatic instruction in the doctrines of the church, the early fathers, and the Scriptures. Theology was as yet not organized into a philosophical system that was the great work the middle ages had to perform. The seven liberal arts (divided into the *Trivium*—grammar, dialectic, rhetoric, and the more advanced *Quadrivium*—geometry, arithmetic, music, astronomy) were a legacy from old Roman education through the transition centuries. They appear in the *Disciplinarum libri IX* of Varro in the 2nd century B.C. But they reached the middle ages chiefly through the summaries of writers in the transition centuries, of which the best known were the *De nuptiis Philologiae et Mercurii* of the Neoplatonist Martianus Capella, who wrote probably early in the 5th century, the *De artibus ac disciplinis liberalium litterarum* of the Christian Cassiodorus (c. 490-c. 585), and the *Etymologiarum libri XX* of St. Isidore of Seville (570-636).

The scope of the arts was wider than their names would suggest in modern times. Under grammar was included the study of the content and form of literature, and in practice the teaching varied from a liberal literary culture to a dry and perfunctory study of just enough grammar to give some facility in the use of Latin. Dialectic was mainly formal logic. Rhetoric covered the study of law, as well as composition in prose and verse. Geometry was rather what is now understood by geography and natural history, together with the medicinal properties of plants. Arithmetic, with the cumbersome Roman notation, included little more than the simplest practical calculations required in ordinary life and the computation of the calendar. Music embraced the rules of the plain song of the church, some theory of sound and the connection of harmony and numbers. Astronomy dealt with the courses of the heavenly bodies, and was seldom kept free from astrology. In philosophy the current textbooks were the *De consolatore philosophiae* of Boethius (470-524), an eclectic summary of pagan ethics, and the same writer's adapted translations of the *Categories* and *De interpretatione* of Aristotle and of Porphyry's *Introduction to the Categories*.

Scholastic Revival.—In the 11th century Europe had settled down, after centuries of war and invasion, into a condition of comparative political stability, ecclesiastical discipline and social tranquillity. The barbarians had been converted, and civic life had developed in the fortified towns of Italy, raised as defenses against the pressure of Saracen and Hungarian invasions. Soon, communication with the east by trade and in the crusades, and with the highly cultivated Moors in Spain, further stimulated the new burst of intellectual life. Arabic renderings of some of the works of Aristotle and commentaries on them were translated into Latin and exercised a profound influence on the trend of culture. A new translation of Aristotle's *Metaphysics* appeared in 1167, and by the beginning of the 13th century all his physical, metaphysical and ethical treatises were available, and during the next half century the translations from Arabic and other Semitic versions were superseded by renderings direct from the original Greek. It was only when the real Aristotle was known that it was found possible to bring the Peripatetic philosophy into the

EDUCATION, HISTORY OF

service of theology. There were thus two broad stages in the educational revival commonly known as scholasticism. In the first the controversies were essentially metaphysical, and centred around the question of the nature of universals, the orthodox theological party generally supporting realism, or the doctrine that the universal is the true reality, of which particulars and individuals are only appearances, while the opposite doctrine of nominalism—that universals are “mere sounds” and particulars the only true existences—showed a continual disposition to lapse into heresies on the most fundamental doctrines of the church. The second stage was essentially constructive, the opposition of philosophy to theology was negated, and philosophy gave a systematic form to theology itself. The most characteristic figure of the former period was Abelard (1079–1142), of the latter St. Thomas Aquinas (1225–74). The former knew little of Aristotle beyond the translations and adaptations of Boethius, but he was essentially a dialectician who applied his logic to investigating the fundamental doctrines of the church and bringing everything to the bar of reason. This innate rationalism appeared to bring theology under the sway of philosophy, and led to frequent condemnations of his doctrines as heretical. With St. Thomas, on the other hand, the essential dogmas of Christianity must be unquestioned. In his *Summa theologiae* he presents all the doctrines of the church systematized in a mould derived from the Aristotelian philosophy.

It is evident, then, that during the period of the scholastic revival men's interests were specially occupied with questions concerning the spiritual and the unseen, and that the great instrument of thought was syllogistic logic, by which consequences were deduced from premises received as unquestionably true. There was a general acceptance of the authority of the church in matters of belief and conduct, and of that of Aristotle, as approved by the church, in all that related to knowledge of this world.

Before the rediscovery of Aristotle exerted such a general influence on the form of education, there was a real revival of classical literary culture at Chartres and a few other schools, and John of Salisbury (d. 1182) in his *Metaphysics* advocated literature as an instrument of education and lamented the barrenness of a training confined to the subtleties of formal logic. But the recrudescence of Aristotle accelerated the movement in favour of dialectic, though at the same time it furnished topics on which logic could be exercised which only a bare materialism can esteem unimportant. The weaknesses of the general educational system which grew up within scholasticism were that haste to begin dialectic led to an undue curtailment of previous liberal culture, and that exclusive attention to philosophical and theological questions caused a neglect of the study of the physical world and a disregard of the critical functions of the intellect. Doubtless there were exceptions, of which perhaps the most striking is the work in physical science done at Oxford by Roger Bacon (1214–94). But Albertus Magnus (1193–1280), the master of St. Thomas, was also a student of nature and an authority for his day on both the natural and the physical sciences. And the work of Robert Grosseteste (d. 1253), as chancellor of the University of Oxford, shows that care for a liberal literary culture was by no means unknown. Probably the most striking instance of the stimulating effect of this premature specialization may be found in the fact that the encyclopedists of general information which were in general use during the middle ages show little or no advance in positive knowledge upon the treatment of similar subjects in Isidore of Seville.

Foundation of Universities.—The services of scholasticism to the cause of education, however, cannot well be overestimated. Aided the content of scholastic studies was in fundamental harmony with the intellectual interests of the time. Above all other benefits owed by future ages to scholasticism is the foundation of the universities of western Europe. (See UNIVERSITIES.)

The concentration of higher instruction in universities was not antagonistic to the mediaeval conception of the church as the teacher or mankind. University life was modelled on that of the cloister, though the monastic ideal could not be fully realized, and the scholars not infrequently exhibited considerable licence in life. This was inevitable with the very large numbers of the

scholars and the great variations of age among them. Moreover students and to a less extent teachers passed from university to university, so that the universities of mediaeval Europe formed a free confederacy of learning in close relation to the church but untrammelled by state control. Nevertheless, the introduction of studies derived from the Greeks through the Arabians led to an increased freedom of thought, at first within authorized limits, but prepared, when occasion served, to transcend those limits. The scheme of instruction was arranged on the assumption that special studies should be based on a wide general culture. Thus of the four faculties into which university teaching was organized that of arts with its degrees of *Baccalaureus* and *Magister*, was regarded as preliminary to those of theology, law and medicine. It often included, indeed, quite young boys, for the distinction between grammar school and university was not clearly drawn. Little or no attempt was made to extend the bounds of knowledge, the aim was to pass on a body of acquired knowledge regarded as embracing all that was possible of attainment, and the authority of Aristotle in physics as well as in philosophy, and of Galen and Hippocrates in medicine was absolute. The methods of instruction—by lecture, or commentary on received texts and by disputation, in which the scholars acquired dexterity in the use of the knowledge they had absorbed—were in harmony with this conception and were undoubtedly thoroughly well suited to the requirements of an age in which the ideal of human thought was not discovery but order, and in which knowledge was regarded as a set of established propositions, the work of reason being to harmonize these propositions in subordination to the authoritative doctrines of the church.

Such an extension of the means of higher education as was given by the universities was naturally accompanied by a corresponding increase in schools of lower rank. Not only were there grammar schools at cathedral and collegiate churches, but many others were founded in connection with chantries, and by some of the many guilds into which mediaeval middle class life organized itself. In addition to the grammar schools were writing and song schools of an elementary type, in which instruction was usually in the vernacular. Girls were taught in women's monasteries and in the home, and those of the upper classes, at least, very generally learned to read, write and keep accounts, as well as fine needlework, household duties and management, and such elementary surgery and medicine as served in cases of slight daily accidents and illnesses. Even those boys and girls who did not receive formal scholastic instruction were instructed orally by the parish priests in the doctrines and duties of the Faith, while the pictures and statues with which the churches were adorned aided the direct teaching of sermons and catechizing in giving a general knowledge of Bible history and of the legends of the saints.

No doubt, in times of spiritual and intellectual lethargy, the practice fell short of the theory, but on the whole it may be concluded that in mediaeval times the provision for higher instruction was adequate to the demand, and that, relatively to the culture of the time, the mass of the people were by no means sunk in brutish ignorance. Indeed, especially when the paucity of books before the invention of printing is borne in mind, the number of people who could read the vernacular, as evidenced by the demand for books in the vulgar tongue as soon as printing made them available, is clear proof that the latter part of the middle ages was by no means a time of general illiteracy.

The page received direct instruction in reading and writing, courtly amusements, such as chess and playing the lute, singing

and making verses, the rules and usages of courtesy, and the knightly conception of duty. As a squire he practised more assiduously the lightly exercises of war and peace, and in the management of large or small bodies of men he attained the capacity of command.

With the unification of existing knowledge and the systematization of theology the constructive work of scholasticism was done. At the same time the growth of national feeling was slowly but surely undermining feudalism. Moreover, deep resentment was accumulating throughout western Europe against the practical abuses which had become prevalent in the church, and especially in the court of Rome and in the prince bishops of Germany. In such conditions the custom and traditional education of school and university tended to lose touch more and more completely with the new aspirations and views of life. Had a new cultural movement not begun, the education of Europe threatened to become as arid as the rhetorical education of the last centuries of the Roman empire had been. From this it was saved by the renaissance of classical studies which began in the 14th century.

The Renaissance—Ever since the 11th century the cities of northern Italy had been in advance of Europe beyond the Alps both in culture and in material progress. The old classical spirit and the feeling of Roman citizenship had never quite died out, and the *Divina commedia* of Alighieri Dante (1265-1321) furnishes evidence that the poet of the scholastic philosophical theology was also a keen student and lover of the old Latin poets. But the greatest impulse to the revived study of the classics was given by Petrarch (1304-74) and Giovanni Boccaccio (1313-75). Generally throughout western Europe the 14th century, though full of war and political unrest, was a time of considerable intellectual activity, shown in the increase of schools and universities, as well as in the literary and artistic revival in Italy, in the social and theological movement in England and Bohemia associated with the names of John Wycliffe and John Huss, and in the more or less complete substitution of Roman law everywhere except in England for the law of custom which had hitherto prevailed.

But it was the literary movement which most affected education, and indeed, the whole life of Europe. A decisive step was taken when Manuel Chrysoloras was invited to teach Greek in the University of Florence in 1397. The enthusiasm for classical culture, to which Petrarch had given so great an impetus, gathered force and extended over the whole of Italy, though, of course, felt only by a select few and leaving the mass of the people little, if at all, affected. From Italy it spread gradually to countries north of the Alps. In the old writers men found full expression of the new spirit of self-conscious freedom which was vaguely striving for expression throughout the whole of Christendom. In the free political atmosphere of the Italian communes, with their wealthy and leisured merchant class, that spirit could flourish much more readily than in the feudalized Europe across the Alps. Moreover, the antique spirit was in direct line of ancestry with that of medieval Italy. Thus for a couple of centuries, Italy stood in the van of European culture.

It is the spirit of the new movement which is of interest to the student of education. And that spirit was essentially one of opposition to authority and of assertion of individual liberty, which worked itself out in various forms among peoples of different temperaments. In Italy the form was literary and artistic, and the full development of the Renaissance spirit was seen in a practical paganism which substituted the attractions of art for the claims of religion and morality, and entertained in deep and widespread immorality, and a contemptuous tolerance or the outward observances of religion without faith in the doctrines they symbolized. The most valuable service of the Italian humanists to Europe was the restoration to man of the heritage of knowledge which he had been allowed to slip from his grasp, and the leading the way to a freer intellectual atmosphere. In Germany the spirit manifested itself in a rebellion against the doctrinal system of the Church as the only effective means of attaining reform of ecclesiastical abuses. The Protestant Reformation of Martin Luther was the real German outcome of the Renaissance. In no other

country of Europe did the movement take so distinctive a form.

The revival of interest in classical studies was, therefore, only a first step. These newly discovered literatures responded to the intellectual and moral cravings which had been blindly gathering force for generations, as they encountered in them the pagan view of life with its assumption of the essential worth and self-reliance of the individual and its frank delight in all the pleasures of existence. It was in just this pagan view of individual worth and the supremacy of the human intellect, that the church gradually realized the supreme danger to herself.

At first the revival of interest in the classical literatures did not show any antagonism to Catholic faith and practice, and its warmest supporters were faithful sons of the church. The view of the relation of classical literature to Christianity adopted by the great humanist schoolmaster Vittorino da Feltre (1378-1446) was broadly that of the early fathers, and in his school at Mantua he showed that culture was not inconsistent with loyalty to the church or with purity of life. With him classical literature was not the end and sum of education, but was a means of implanting ideas, of developing taste and of acquiring knowledge, all as helps and ornaments of a Christian life. The school at Mantua may, indeed, be said to have exhibited in practice a Christianized application of the doctrines of Quintilian and Plutarch.

So was it in the other countries of Christendom. In the Netherlands the Brethren of the Common Life introduced humanistic studies into their schools side by side with definite religious teaching and observances and their work was always dominated by the Christian spirit. The earlier German humanists, such as Nicholas de Cusa, Alexander Hegius, Johannes Agricola and Jakob Wimpfeling, adopted the same attitude, and Erasmus himself, bitterly as he attacked the practical abuses of the church, remained in communion with it, and aimed at harmonizing classical culture with the Christian life. In England the same love of culture combined with devotion to the church was seen in Selling, prior of Christ church, Canterbury, the first real English humanist, in William Grocyen, Thomas Lanacre, Sir Thomas More, John Fisher, John Colet and many others whose enthusiasm for culture was as undoubted as was their loyalty to Catholicism. It seemed, then, at first as if the greatest educational effect of the classical revival would be the deepening of literary culture, and the substitution of real inquiry for dialectic subtleties in the courses of schools and universities, without any break with established religious teaching. It is true that the majority of schools were but little affected, and many of the universities had given but a half-hearted welcome to humanistic studies when the religious revolt in Germany under the leadership of Luther threw the whole of Europe into two hostile camps. But even the conservative University of Paris—the headquarters of scholastic philosophical theology—had permitted the teaching of Greek as early as 1458, and both Oxford and Cambridge had welcomed the new studies.

The Reformation—The immediate effect of the religious controversies of the 16th century on education was disastrous. The secularization of ecclesiastical property too often absorbed the endowments of the schools, so that, both in Germany and in England, the majority of grammar schools either disappeared or continued a starved existence, with diminished funds, the doctrine of salvation by faith alone and the futility of good works dried up the source from which such endowments had flowed, the violent fulminations of the German reformers against the universities as the homes of the hated scholastic theology and philosophy led to wholesale abstention from those seats of learning, while the logical speculations and quarrels led those few who did resort to the universities to devote their energies to interminable wrangling over controversial points. This decadence in culture was attended by an outbreak of licence and immorality, especially among the young, which called forth violent denunciations from Luther and many of his followers in Germany, and from Hugh Latimer and other reformers in England. Humanism and Protestantism, which had so far diverged that Erasmus (1467-1536) had declared that where Lutheranism flourished learning decayed

were brought together again by Philipp Melancthon (1497-1560), under whose influence universities were founded or reorganized and schools reestablished in Protestant German states, and in England the reign of Elizabeth saw the creation of a certain number of new foundations. But this restoration of the means of education was only partial, and the doctrine of the worthlessness of "carnal knowledge," which led the Barebones parliament to propose the suppression of the English universities, was held by many fervent Protestants both in England and in Germany all through the 17th century.

Moreover, the schools continued to ignore the new directions of men's thoughts and the new view of knowledge as something to be enlarged and not merely a deposit to be handed down from generation to generation. The later humanist theories of education which the schools continued to follow generally for more than two centuries, and in many cases for another hundred years after that, were drawn mainly from Erasmus and Melancthon, who found in the classical languages and literatures, and especially in Latin, the only essential instruments of education. General knowledge of natural facts might be desirable to the cultured man as ornaments to his rhetoric but it was to be sought in the writings of antiquity. Even so revolutionary a thinker on education as François Rabelais (1495-1553) with all his demand for an encyclopaedic curriculum, held the writings of the ancients as authoritative on natural phenomena. Melancthon exercised enormous influence both directly and through such disciples as Valentin Trottendorff and Neander, but especially through his friend John Sturm (1507-1589), whose Latin gymnasium at Strasbourg became the model which the grammar schools of Protestant Europe strove to imitate. In this school nearly the whole of the energies of the boys was given to acquiring a mastery of the Latin language after the model of Cicero.

In Catholic countries the church retained control of education. The practical reformation of abuses by the Council of Trent, and the energy and skill of the Society of Jesus, founded by St Ignatius Loyola in 1534, brought back most of south Germany into the fold of the church. Everywhere Catholic universities were mainly taught by Jesuit fathers, and under their influence, scholasticism, purged from the excretions which had degraded it, was restored. Everywhere the society established schools, which, by their success in teaching and the mildness of their discipline, attracted thousands of pupils who came even from Protestant homes. Their curriculum was purely classical, but it was elaborated with much skill, and the methods of instruction and discipline were made the subject of much thought and of long-continued experiment. All Jesuit fathers being trained, the teachers in Jesuit schools attained a degree of skill in their art which was too generally wanting elsewhere.

Decadence of Schools and Universities.—Richard Mulcaster (1530-1611) pointed out that Latin was not of value to the majority of boys. For them he urged an elementary education in the vernacular, but neither in this nor in his advocacy of the training of teachers was his advice followed. In the 17th century the dislocation between the Latin schools and the needs of life began to be accentuated as Latin gradually ceased to be the language of learning, and, as a consequence, the numbers attending the schools decreased, and the mass of the people sank continually lower in ignorance. In vain Charles Hoole urged the establishment of a universal system of elementary schools giving instruction in the vernacular, Sir William Petty put forth his plan for elementary trade schools, and Abraham Cowley proposed the establishment of a college devoted to research. Ideas of reform were in the air, but the main current of scholastic practice flowed on unaffected by them. Some attention was, indeed, paid to the conservative reforms advocated by the Port Royalists, of which the most important was the inclusion of the vernacular as a branch of instruction, but the cry for more fundamental changes based on the philosophy of Roger Bacon was unheeded. Of these, none was a more active propagandist than Johann Comenius (1592-1670). Unfortunately his *Great Didactic*, in which he set forth his general principles, attracted little attention and won less adherence, though his school books, in which he attempted with very

little success to apply his principles, were widely used in schools. But these were little more than bald summaries of real and supposed facts, stated in Latin and the vernacular in parallel columns. In content they differed from such medieval summaries of knowledge as the well known work of Bartholomew Anglicus, which had been widely used since the 13th century, chiefly by their greater baldness and aridity of statement.

In the universities, too, the 16th and 17th centuries saw a continuous decadence. The 16th century was not ripe for real intellectual freedom, and Protestantism, having based its revolt on the right of private judgment, soon produced a number of conflicting theological systems, vying with each other in rigidity and narrowness, which, as Friedrich Paulsen says, "nearly stifled the intellectual life of the German people." Further, the idea of national autonomy, which exercised so great an effect on the politics of the time, included the universal adherence of the citizens to the religion of the state. Hence, till the end of the 17th century the universities of Protestant Europe were regarded mainly as instruments for securing adhesion to the national theological system on the part of future clergy and officials, and the state interfered more and more with their organization and work. In Paris, on the other hand, the faculty of theology had decayed through the withdrawal of those preparing for the priesthood into episcopal seminaries, and the higher studies pursued were mainly law and medicine. Thus, generally, the universities were less and less fulfilling the function of providing a general liberal education. Another change, arising from the same causes and making for the same results, was the isolation of universities, often directly fostered by the state governments, which for the universal interchange of mediaeval thought substituted a narrow provincial culture and outlook.

Indeed, from the middle of the 17th century, the main current of intellectual life had drifted away from the orthodox centres of learning. The formation of the Berlin academy in Germany and of the Royal society in England, and the refusal of Gottfried Leibnitz to accept a chair in any German university, were signs of the times. In France, and later in Germany, the education of the noble youth was increasingly carried on apart from the schools, and was really an outgrowth from the education of chivalry. In the 16th century Baldassare Castiglione and Michel de Montaigne had advocated a training directly adapted to prepare for active public life, and Sir Thomas Elyot wrote on similar lines. But the most important movement in this direction was the formation of the courtly academies which flourished in France in the 17th century, and were soon imitated in the *Ritterakademien* of Germany. In these schools of the nobility French was more honoured than classics, and the other subjects were chosen as directly adapted to prepare for the life of a noble at the court or in camp. John Milton in his *Tractate* advocated the foundation of such academies in England. More and more, too, foreign travel had, from the middle of the 16th century, been looked upon as a better mode of finishing the education of a gentleman than a course at a university.

Revival of University Life.—The later years of the 17th century saw a revival of university life in Cambridge, through the work of Sir Isaac Newton and the increasing attention paid to mathematics and the physical sciences, though the number of students continued very small. In Germany, also, a new era opened with the foundation of the Universities of Halle (1693) in 1694 and Göttingen in 1737, which from the first discarded the old conception that the function of a university is to pass on knowledge already complete, and so opened the door of the German universities to the new culture and philosophy. It was soon seen that students could thus be attracted, and the influence spread to the other German universities, which by the end of the 18th century had regained their position as homes of the highest German thought.

At Halle, too, was set the example by August Francke of providing for the education of the children of the poor, and to his disciple, Johann Julius Hecker, Germany owes the first *Realschule*. Simultaneous movements for the education of the poor were made by St. Jean Baptiste de la Salle and the Brothers of the Christian

Schools in France and by the Society for the Promotion of Christian Knowledge in England. Mention should also be made of the Sunday School movement started by Robert Raikes in 1780. But the total results were not great; the mass of the people in every European country remained without schooling throughout the 18th century.

Education in the 18th Century.—The intellectual movements of that century were indeed, essentially aristocratic. Voltaire and the Encyclopedists aimed at the enlightenment of the select few, and Jean Jacques Rousseau declared baldly that the poor need no education. That these movements influenced education profoundly is undoubted. The individualistic and abstract rationalism of Voltaire, derived from the sensationist philosophy of John Locke through the more thoroughgoing Étienne de Condillac and finding its logical outcome in the materialistic atheism of Julien de Limettrie and the refined selfishness of Rochefoucault, infected the more cultured classes. In Lord Chesterfield's *Letters to his Son* is shown its educational outcome—a veneer of superficial culture and artificial politeness covering, but not hiding, the most cold blooded selfishness. Against this fashionable artificiality, as well as against the obvious social and political abuses of the time, Rousseau's call for a return to nature was a needed protest.

Rousseauism, however, was not merely a transitory revolt against a conventionality of life that had become unbearable, it was emphatically the voicing of a view of life and of education which profoundly influenced Europe. In that Rousseau (1712-1778) attempted to look at life as a whole, he was on truer ground than were the intellectualists of the "Enlightenment," especially in his advocacy of the hitherto ignored claims in education of feeling and emotion. His *Emile* may be, in spite of certain crudities, not unfairly described as the charter of childhood. It is, in fact, a declaration of childhood's rights. On the other hand, his overinsistence on the efficacy of nature, as shown by his theory that man is born good, and if left to his own instincts cannot fail to achieve happiness, is obviously one-sided.

Against this position the educational teaching of Immanuel Kant (1724-1804), influenced though he was by the *Emile*, is essentially a protest. The most necessary element in education, according to Kant, is constraint, which by the formation of habit prepares the young to receive as principles of conduct the laws at first imposed upon them from without. And the supreme guide of life is the law of duty which is always more or less opposed to the promptings of inclination. The French Revolution—the natural outcome of the teachings of Voltaire and of Rousseau—was the second stage in the movement of which the Reformation was the first. It was essentially the assertion of the natural rights of man, and as a logical sequence, of the right of every child to be properly trained for life. The gradual recognition of this truth, with the necessary corollary of the establishment of a national system of education, is emphatically the characteristic mark of the educational history of all countries in the 19th century.

The 19th Century.—Preached and practised by Johann Pestalozzi (1746-1827) in Switzerland, the general education of the poor was first made a reality by Prussia after the crushing defeat of Jena. In France and England it remained for nearly three quarters of the century the work of the church and other voluntary agencies though aided by the state. Finally a state system of schools was more or less set up in every state of Western Europe and in America, and submitted to more or less strict regulation and control. Equally marked was the growing care for the education of girls as well as boys, though only in the U.S. were the two regarded as practically identical in form and content.

Thus the 19th century saw the final working out of the idea that the state should be substituted for the church as the official agent of education. Among the principal causes of such a change was the growing conviction that with the ever widening distribution of political power the state had a right to demand a minimum of knowledge from every citizen, while on the other hand, it is alike to the benefit of the individual and the state that the door of educational opportunity should be thrown as wide open as possible. Equally potent was the idea which had its roots in the

Renaissance conception of the right of man to direct his life apart from theological determinations. The more direct outcome of the same idea was apparent in the absolute liberty with which the presuppositions of knowledge were questioned, and the maxim of René Descartes—to prove everything by the reason and to accept nothing which fails to stand the test—was acted upon. No greater contrast is possible than that between the mediaeval student and the modern searcher after truth.

The influence of the same spirit wrought an equally momentous change in the methods of instruction. The impetus given by the doctrine of Rousseau to the view that the nature of the child should determine the means of education, led to more thoroughgoing attempts than had hitherto been made to base educational method on a knowledge of child psychology. Pestalozzi and Friedrich Froebel (1782-1852), by their insistence on the need of educating a child through his own activity, and by their widespread influence, made the new view of method an actuality. The influence of Rousseau thus passed into modern educational practice in a form that, in its essence, was true, though in practice it showed itself apt to run into the same excess of emphasis on impulse and feeling which characterizes his teaching. The influence of Johann Herbart (1776-1841) tended to counteract this. The essence of Herbartianism was that mental life consists of presentations, or reactions of the mind on the environment, and that will springs from the circle of thought thus developed. The emphasis was therefore placed on intellect and instruction, while in Froebelianism it was placed on spontaneous activity and on the arrangement of the environment. Each exaggerated the function of the one factor in concrete experience which it made the centre of interest, and each was tinged with the individualistic conception of life which characterized the 18th and early 19th century. HISTORY OF NATIONAL SYSTEMS

ENGLAND (19TH AND 20TH CENTURIES)

Elementary Education.—It was the development of industry and the social unrest at the end of the 18th century, following on the French Revolution, which combined to bring home to the public mind the need of a national system of day schools. Unfortunately, just at this moment the revival of Nonconformity as the result of the religious vitality of the Evangelical movement shattered the religious peace of the early Hanoverian period and divided the nation once more into hostile camps, to which class distinctions lent additional bitterness. The famous controversy between Andrew Bell and Joseph Lancaster and their respective followers in the opening years of the 19th century served to define the religious difficulty substantially in the form in which it existed for more than 100 years. Both these remarkable men conceived independently the idea of a national system of popular education upon a voluntary basis. The controversy between them, begun upon personal grounds, resolved itself into a national contest of rival principles of religious teaching. Lancaster as a young Quaker schoolmaster confronted with pupils drawn from various religious bodies, planned his religious instruction upon the lines of doctrine common to all the orthodox Christian denominations. Thus he is the father of the undenominational religious teaching which later formed the basis of the Cowper Temple compromise of 1870 act (see below). But whereas the Cowper Temple clause was purely negative in its terms and so seemed to point to an undogmatic religion, the Lancasterian teaching was essentially positive and dogmatic within its limits. The church as a whole refused to co-operate in religious teaching upon the basis of a common Christianity and joined issue with Lancaster and his Whig and Nonconformist following not merely upon the question of the exclusion of dogmatic formularies, but also upon the question of the control of whatever religious teaching should be given. In fact the vital question at this period was whether the clergy of the established church were to control the national education. The religious issue was prominent in connection with the remarkable attempt at legislation made by the Whig statesman Samuel

Whitbread in his Parochial Schools bill of 1807. It was rejected by the lords, mainly on the ground that it did not place education on a religious basis or sufficiently secure control to the minister of the parish.

Early Voluntary Schools—The failure of the liberal proposals of Whitbread, and the strength of the dissenting opposition to any settlement on purely church lines (such as that advocated by Andrew Bell in 1808 for establishing schools under the control of the parochial clergy), rendered recourse to voluntary effort inevitable. In 1808 the Royal Lancasterian society was formed to carry on the work of Lancaster, the name being afterward changed to the British and Foreign School society. In the following year the National society for promoting the education of the poor in the principles of the established church throughout England and Wales was formed, with Bell as its superintendent. In voluntary effort on a grand scale the church easily outdistanced her opponents, and in 1837 the National society was able to show that there were in all more than 13,000 schools in connection with the church of which 6,470 were both day and Sunday schools, having a total attendance of 409,000.

The rapid development of the voluntary school system was no doubt greatly facilitated by the monitorial plan of teaching, upon which Bell and Lancaster equally relied. This plan never rested upon any educational theory, it was simply a rough and ready expedient for overcoming the practical difficulty caused by the dearth of competent teachers. Historically it is important as the precursor of the pupil teacher system which long formed the exclusive basis of the English elementary system.

Meantime Lord Brougham in 1816 procured the appointment of a general commission of inquiry into endowed charities. The labours of this great inquiry lasted for 20 years and led to the reformation of many cases of abuse or waste of wealthy endowments, and eventually to the establishment of the Charity Commission in 1853. In 1820 Brougham introduced a bill which proposed to require teachers to be members of the Church of England and to be appointed upon a certificate from the parochial clergyman, and on the other hand to prohibit religious formularies and to confine religious instruction to Bible reading without comment. The bill naturally failed through the opposition of the dissenters and served only to accentuate the religious impulse.

Establishment of State Aid—In 1832 the Whig government placed on the estimates a sum of £20,000 for public education, thus initiating the system of the annual grant voted by parliament. The funds thus granted were to be confined to the erection of school buildings, and to be administered only through the National and the British and Foreign School societies. In 1839 Lord Melbourne's government, by means of an order in council, established a Committee of Council on Education, and the sum voted by parliament was increased to £39,000. The original intention of the government was to establish a state normal school or training college as the foundation of a national system of education. Unfortunately this design had to be abandoned in view of the religious difficulty, with the result that the training of elementary teachers was left in private hands. In view of the limited resources placed at its disposal by parliament, the committee of council was at first compelled to confine its assistance to capital grants in aid of the provision of school buildings, but in the distribution of the money three important conditions were at once imposed. In the first place, the continuing right of inspection was required in all cases, secondly, promoters were obliged to conform to a fixed standard of structural efficiency, thirdly, the building must be settled upon trusts permanently securing it to the education of poor children.

By the minute of Aug. 10, 1840, the committee of council concluded what came to be known as the concordat with the church. Under this minute no appointment was to be made of any persons to inspect schools in connection with the Church of England without the concurrence of the archbishop of the province, and what seems still more extraordinary to modern ideas, any such appointment was to be revoked should the archbishop at any time withdraw his concurrence. The altered financial relations, however, between the state and the voluntary managers brought about

by the institution of maintenance grants soon rendered this concordat obsolete.

Among the first acts of the committee of council was the promulgation of a set of model trust deeds. The necessary conditions were the permanent appropriation of the site to purposes of education, and the permanent right of government inspection, a conscience clause was not obligatory, and indeed was only offered in the limited form of exemption from instruction in formularies and attendance at Sunday school or public worship. Special facilities for the conveyance of land for school purposes were afforded to limited owners by the School Sites acts of 1841 and subsequent years. The landed gentry responded with great public spirit to the call thus made upon their generosity by the state, with the result that the vast majority of rural, and many urban parishes were freely endowed with sites for elementary schools.

The Grammar Schools act of 1840 which was passed to deal with the case of the decayed "grammar" (i.e., classical) schools which abounded throughout the country belongs to the history of elementary rather than secondary education. As a result of this act a considerable number of ancient endowments were reorganized so as to afford an improved elementary instead of an inefficient classical education, and the schemes made under the act constituted an early, but not very successful, experiment in the direction of higher elementary schools.

In 1843 the committee of council decided to make grants in aid of the erection of normal schools or training colleges in connection with the National society and the British and Foreign School societies, thus marking the definite abandonment of the system of relying on voluntary effort for the provision of training colleges.

In 1846 an important step forward was taken in the foundation of the pupil teacher system. The regulations of this year inaugurated annual maintenance grants in the form of stipends for apprenticed pupil teachers receiving a prescribed course of instruction under the head teacher, and a lower grade of stipendiary-monitors in schools where such instruction could not be provided. These regulations inaugurated the system of Queen's scholarships to assist pupil-teachers to proceed to a training college, they also established capitation grants for the support of such colleges, and annual grants to elementary schools under government inspection of from £15 to £30 in aid of the salary of every trained teacher employed. Provision was at the same time made for retiring pensions to elementary teachers.

To facilitate the recognition of denominational schools other than Church of England, the committee of council in 1847 issued a minute dispensing schools not connected with the established church from inquiries concerning their religious condition, and in the same year state aid was extended to Wesleyan and Roman Catholic schools. Jewish schools received recognition in 1851 upon condition that the Scriptures of the Old Testament should be daily read in them.

During the middle years of the century various unsuccessful legislative attempts were made to establish a national system of elementary schools upon the basis of rate aid. The only one of these attempts which calls for notice here is the bill introduced by Lord John Russell (called the Borough bill, on account of its being restricted to municipal boroughs) in 1853, and forming part of a comprehensive scheme of legislative and administrative reform of which a portion was actually carried into effect. The bill as a measure for elementary education was supplemented by an administrative system of capitation grants for rural areas. The government scheme also comprised a measure dealing with the administration of charitable trusts (which took shape as the Charitable Trusts act, 1853), the constitution of the department of science and art, and university reform upon the lines recommended by the Oxford and Cambridge commissions.

The failure of the Borough bill did not affect the new system of capitation grants which was introduced by minute of the committee of council dated April 2, 1853. These grants were fixed at a scale varying from 3s to 6s per head, payable upon certain conditions, of which the most important were that the school must be under a certificated teacher, and that three-fourths of the

children must pass a prescribed examination. The capitation grant was, by minute of Jan. 16 1856, extended to urban areas. As in the case of all the early grants, the regulations governing the distribution of the capitation grants were framed upon the principle that subventions of public money must be met by local funds derived from voluntary contributions, endowments and school fees, thus the basis of the denominational system as fostered by the state at this stage was one of financial partnership.

In 1856 a purely administrative bill was passed, establishing the office of vice president of the Committee of Council on Education as a minister responsible to parliament. At the same time, the science and art department was transferred from the board of trade to the committee of council.

The Newcastle Commission.—The progress of state aided education during this period may be measured by the increase of the annual parliamentary grant, which rose from £30,000 in 1839 to £100,000 in 1846, £150,000 in 1851, £390,000 in 1855, and £663,400 in 1858. This expansion was viewed with misgiving by the friends of the denominational system and by the strong individualist school of that day, who upon wider grounds clung to the old ideal of voluntary initiative. These sections combined with the advocates of further state intervention to press for a commission of inquiry and a royal commission was appointed in 1858, under the chairmanship of the duke of Newcastle to inquire into the state of popular education in England, and to consider and report what measures, if any, were required for the extension of sound and cheap elementary instruction to all classes of the people. The *Report of the Newcastle commission* issued in 1861, contained an exhaustive account of the existing condition of elementary education, and with due allowance for the grave defects revealed, and in particular the glaring inefficiency of the numerous little private-venture schools kept by "dames" and others, the graphic picture drawn by the commissioners constituted a striking tribute to the sterling qualities of self help and religious earnestness which were characteristic of the early Victorian period. It was found that in round numbers about 2,500,000 children were attending day schools, the proportion to population being one in seven, as compared with one in nine in France, one in eight in Holland and one in six in Prussia, where education was compulsory. On the other hand, of this number only 1,675,000 were in public schools of all kinds, only 1,100,000 in schools liable to inspection, and 917,000 in schools receiving annual grant. The result was that only one child in every 20 was attending a school whose efficiency could be in any way guaranteed by the state. The commissioners as a body rejected free and compulsory education in view of the religious difficulty and upon general grounds of individualistic principle. In view of the solution adopted in 1902 it is of interest to note that the Newcastle commissioners deliberately rejected the parish as unfit to be taken as the unit of elementary education upon the ground that management by parochial ratepayers must tend to be illiberal and nigardly, and recommended the constitution of county boards with power to levy a rate for the aid of existing voluntary schools.

The one definite achievement of the Newcastle commission was the famous system of payment by results. Impressed by the defects of the existing teaching, the commissioners reported that there was only one way of securing efficiency, and that was to institute a searching examination by competent authority of every child in every school to which grants were to be paid, with the view of ascertaining whether the indispensable elements of knowledge were thoroughly acquired, and to make the prospects and position of the teacher dependent to a considerable extent upon the results of this examination. They recognized that to raise the character of the children, both morally and intellectually, was and must always be the highest aim of education, but they thought that the training in the rudiments of education, which must be the foundation of all teaching, had been lost sight of, and that there was justice in the common complaint that while a fourth of the scholars were really taught, three-fourths after leaving school forgot almost everything they had learned there.

Lowe (Lord Sherbrooke), as vice-president of the committee of council (1859-64), adopted the system of payment by results

in what became famous in history as the Revised code, issued in 1862. The Revised code provided for the payment of a grant of 4s upon the old principle and a further grant of not more than 8s upon the result of examination. Lowe declared of the system in the house of commons that "if it was costly it should at least be efficient, and if it was inefficient it should at least be cheap." In fact, it proved to be cheap, the grant fell from £813,400 in 1861 to £636,800 in 1865. Later, to meet objections, some modifications were introduced in the code under the Conservative government in 1867. The system of paying grant upon the result of individual examination of the scholars was not finally abolished till 1904.

The Act of 1870 and Its Effects.—In 1868 the Conservative government brought in, but did not proceed with, an education bill deliberately discarding the principle of rate aid on the ground that it would destroy voluntary contributions and gradually starve out the denominational schools. In 1867 and again in 1868, Henry Austin Bruce (afterward Lord Aberdare), W. E. Forster and Algernon Egerton introduced a bill which formed the basis of the measure of 1870. As redrafted in 1868 the bill of Bruce and his coadjutors proposed a universal system of municipal and parochial rating with liberty for voluntary schools to unite themselves to the rate aided system under their existing management, subject to the acceptance of a conscience clause. The bill also proposed to empower town councils to co-opt outsiders upon their education committees. Thus both in the principle of co-optation and in the extension of rate aid to schools not under public control the bill of these Liberal statesmen in 1868 anticipated certain features of Balfour's Education act of 1902. In the meantime, in the country the Education league, originated at Birmingham, was carrying on a propaganda in favour of free secular schools, while the Education union, formed to counteract the influence of the league, urged a settlement upon the old lines. As a concession to the popular feeling against secularism, the league proposed to allow Bible reading without doctrinal exposition. Thus opinion was sufficiently focused to enable William Gladstone's administration in 1870 to undertake a comprehensive measure of educational reform.

The Elementary Education act of 1870 bore in every respect the marks of compromise. As Forster explained in introducing the bill, the object of the government was "to complete the voluntary system and to fill up gaps," not to supplant it. To this end the education department was charged with the duty of ascertaining whether or not there was in every parish a deficiency of public school accommodation, and of making provision for the formation of school boards in every school district (i.e., parish or municipal borough) requiring further public school accommodation.

Three important changes were made in the measure during its passage through parliament. (1) In lieu of the rate aid as first suggested, the government proposed an increased grant from the treasury, that is to say, the voluntary schools were left standing as state aided schools under private management, side by side with the new state supported schools. (2) The character of the religious instruction in the board schools was determined upon an undenominational basis by a provision which became known after the name of its author, as the Cowper-Temple clause (section 14 of the act), directing that "no religious catechism or religious formula which is distinctive of any particular denomination shall be taught in the school." The clause was not intended to exclude doctrinal exposition, and was in fact a compromise not merely between absolute secularism and denominationalism, but between denominationalism and the view of those who would have the Bible read without note or comment. The Apostles' creed as a symbol common to all denominations of Christians was held by Forster (at Gladstone's suggestion) not to be excluded under the Cowper-Temple clause. The result was the establishment of the schools, upon the lines laid down by Joseph Lancaster at the beginning of the 19th century, of what may be termed the common Protestantism of the English nation. The Cowper-Temple compromise, notwithstanding its inherent want of logic, stood the test of experience for more than a generation against the consistent

denominationalists on the one hand and the party of secular education on the other. (3) The third change in the bill was the substitution of the *ad hoc* school board for the municipally appointed board originally proposed. These boards were elected by the system of cumulative voting under which each elector had as many votes as there were candidates to be elected with liberty to give all his votes to one candidate or to distribute them among the candidates as he thought fit. This system was much criticized as being unduly favourable to minorities, whose representation it was devised to secure, it continued, however, until the act of 1902.

School boards were empowered not only to acquire sites for schools under powers of compulsory purchase, but also to take transfers of existing voluntary schools from their managers. The act of 1870 did not introduce either direct compulsory attendance or free education, but it took a distinct step forward in each direction by enabling school boards to frame bylaws rendering attendance compulsory, and also to pay the school fees in the case of poverty of the parent. Building grants were continued temporarily for the benefit of those who applied (as voluntary managers alone could apply) before Dec. 31, 1870. On the other hand, the education department was authorized to refuse parliamentary grants to schools established in school board districts after the passing of the act if they thought such schools were unnecessary.

The following figures are of interest as showing the progress made under the act of 1870. In the year 1870 there was accommodation in inspected day schools for about 2,000,000 children, the average attendance was 1,168,000, and the number on the books about 1,500,000. It was computed, however, that there were, exclusive of the well-to-do classes, at least 1,500,000 children who attended no school at all or schools not under inspection. In 1876 accommodation had been provided for nearly 3,500,000, and of the 1,500,000 new places nearly two thirds were provided by voluntary agencies. "These voluntary agencies," said Sir H. Craik, "had received grants in aid for about one-third of the schools they had built, the grants defraying about one-fifth of the cost of the aided schools." On the other hand, the growth of school boards was rapid and continuous, notwithstanding the permissive character of the act and the strenuous efforts of the voluntarists to keep pace with the new demands. In 1872, 9,700,000 of the population were under school boards, and of these 8,142,000 were under bylaws, in 1876 the numbers were respectively 12,500,000 and 10,400,000. In the same period the annual grants increased from £894,000 in 1870 to £1,600,000 in 1876. The development evidenced by the above figures, and in particular the fact that 52% of the population were subject to bylaws, enabled Benjamin Disraeli's government in 1876 to pass a law introducing universal compulsory attendance, with certain exceptions. In order to complete the machinery for compulsion the act directed that, in every district where there was no school board, a school attendance committee should be appointed by the local authority.

In 1880 Anthony Mundella, as vice-president of the council in Gladstone's administration, passed a short act which made the framing of bylaws compulsory upon school boards and school attendance committees, thus completing the system of universal direct compulsion. Under the acts of 1870 and 1880 the average attendance increased from 2,000,000 in 1876 to 3,500,000 in 1878 and 4,000,000 in 1887. In terms of percentage to population, 8.06% in 1876, 9.60% in 1878, and 10.69% in 1887. In the last-mentioned year the annual grant rose to £2,200,000 having more than doubled in the decade.

In 1887 a royal commission under the presidency of Viscount Cross was appointed to inquire into the working of the education acts. The labours of this commission produced a thorough discussion of the educational problem in all its aspects—political, administrative, scholastic and religious. For any clear recommendations with regard to the reorganization of education generally the moment was not opportune, inasmuch as the commission just preceded the establishment of the new county authorities and the powers with respect to instruction other than elementary which parliament was shortly to confide to them under the Tech-

nical Instruction acts. Nevertheless the report of the majority of the commissioners pointed unmistakably toward the solutions adopted in the act of 1902, and their definite recommendation that voluntary schools should be accorded rate aid without the imposition of the Cowper Temple clause, served as the basis of that legislation.

Of the developments which followed the Cross report, it is convenient to mention in the first place, out of chronological sequence, the practical establishment of free education by the act of 1891, not by the absolute prohibition of school fees but by the device of a special grant payable by parliament in lieu of fees, called the fee grant. The result of this legislation and of subsequent administrative action was to place free education within the reach of every child, fees being retained (with few exceptions) only where some instruction of a higher elementary type was given.

(For provisions of the education act of 1944, see below.)

Secondary and Technical Education.—The establishment of county councils by the Local Government act, 1888, introduced a new factor, destined to exert a determining influence upon subsequent developments of public education. In the first place, it at once rendered possible the partial and experimental provision for higher education attempted by the Technical Instruction acts, which affected secondary education as well as technical education in the proper sense of the term.

In order to understand the state of secondary education at this period it is necessary to refer to the first attempts made at state intervention.

In 1861 the first step was taken by the appointment of a royal commission, presided over by Lord Clarendon, to inquire into the condition of nine of the chief endowed schools in the country, viz., Eton, Winchester, Westminster, Charterhouse, St. Paul's, Merchant Taylors Harrow, Rugby and Shrewsbury. The report of this commission led to a statute, the Public Schools act of 1864, which introduced certain reforms in the administration of seven of these schools, leaving the two great London day schools, St. Paul's and Merchant Taylors, outside its operation.

The Schools Enquiry Commission.—In 1864 the Schools Enquiry commission was appointed under the presidency of Lord Taunton to inquire into all the schools which had not been included either in the commission of 1861 or the Popular Education commission of 1853. It thoroughly explored the field of secondary education, discussing all the problems, administrative and pedagogic, which the subject presents, and "its luminous and exhaustive report" (to quote the words of Bryce's commission of 1894) was an excellent introduction to the problem of public secondary education in England. The existence of numerous and frequently very wealthy endowments arising from private benefactions and bequests had at all times been a feature in education as in other departments of English social life. At the date of the Schools Enquiry commission the state of the ancient endowments was largely one of abuse. Many endowments intended for advanced education were applied for instruction of a purely elementary character, and that of an inferior kind, indeed the possession of an endowment in a rural locality not infrequently operated to prevent the establishment of a superior school. The commission of 1864, however, found that the endowments were generally well managed, and that the schools were generally well conducted. The commission recommended that the endowments should be preserved, but that the schools should be reorganized on a new basis, and that the endowments should be used to assist the movement for the secondary education for girls. Because of their powers in framing schemes for the reorganization of ancient endowed schools the commissioners found

themselves able to treat the majority of cases as undenominational. In such cases the general practice was to direct that instruction should, subject to a strict conscience clause, be given in the principles of the Christian faith, this provision however, did not exclude special doctrinal instruction.

The Schools Enquiry Commission also submitted proposals for the general organization of a system of secondary education. They recommended the establishment of three authorities: (1) a central authority, (2) a local or provincial authority, representing the county or a group of counties, and (3) a central council of education charged with examination duties. Further it was proposed to raise the level of proprietary and private schools by offering them inspection and examination and by establishing a system of school registration. Lastly, it was proposed to confer upon towns and parishes powers of rating for the establishment of new schools. For these proposals as a whole the time was not ripe. The bill of 1869 attempted to give effect to the suggested creation of a central council but exigencies of parliamentary time made it necessary to drop this part of the measure, the result was that the plan of the commissioners was only half carried out. Nevertheless the work accomplished was sufficient to exert a considerable influence upon the secondary education of the country. Thus in 1895 Bryce's Commission was able to report that schemes under the Endowed Schools Acts had been made for 902 endowments in England, excluding Wales and Monmouth, leaving untouched only 546 endowments out of the total of 1,448 endowments in England known to be subject to the Endowed Schools Acts. The total income of the endowments known to be subject to the Endowed Schools Acts, and therefore available for the purposes of secondary education, according to the estimate of the Secondary Education Commission, was in 1895 about £735,000 gross.

The creation by the Local Government Act in 1888 of the representative and popular county authorities rendered the municipalization of secondary instruction at last possible. In 1889 the Technical Instruction Act (extended in some particulars by an act of 1891) empowered the councils of counties, boroughs and urban districts to levy a rate (not exceeding a penny on the pound) for the support or aid of technical or manual instruction. Comparatively few councils were prepared to resort to their rating powers, but progress under these acts was greatly facilitated by the Local Taxation (Customs and Excise) Act of 1890, which mentioned technical instruction as one of the purposes to which the imperial contribution paid to local authorities in respect of the beer and spirit duties might be applied (*See TECHNICAL EDUCATION*). By virtue of the liberal interpretation given to technical instruction by these acts the financial assistance afforded under them was extended to cover the whole field of mathematical and physical science, as well as modern languages.

At the same time the department of science and art (founded in 1853) gradually utilized its grants to encourage literary studies in secondary schools as well as the scientific and mathematical subjects to the promotion of which it was primarily directed. Thus the combined effect of the local resources available under the Technical Instruction Act and the imperial grant administered by the department was gradually to develop a national system of secondary education with a marked bias on the side of physical science. But the school's owner hindered education still practically confined apart from the big public schools, of endowed grammar schools or proprietary schools established by religious bodies or joint-stock companies. No public body had as yet the right to build a secondary school.

An undoubted stimulus was given to secondary education in the great centres of industry during the last quarter of the 19th century by the rise of the new university colleges, among which must be reckoned those established expressly for women. At the same time (1899) a beginning was made of state aid to these colleges through a committee appointed by the treasury in a minute of July 1 (see *UNIVERSITIES*). Meanwhile with the development of elementary education, the great school boards found themselves obliged to provide for the further education of their

best pupils in what were known as higher-grade elementary schools. These were really secondary schools of the third grade, and, as the commission on secondary education observed, the school boards simply stepped in to fill the educational void which the Schools Enquiry commissioners had proposed to fill by schools of that name. Their creation was greatly fostered by the upper departments in such schools being recognized for grants by the science and art department. In fact they continued to multiply and prosper till 1901, when the famous judgment in the test case of *Rex v. Cockerton* pronounced them to be illegal. It was at once recognized that the legislature must, without delay, step in to secure the educational work which the undoubtedly correct principles of judicial interpretation had placed in jeopardy.

Secondary Education Commission.—Meanwhile, as far back as 1894, a royal commission had been appointed under the presidency of James Bryce to inquire into secondary education. The principal recommendations of the commission were (1) the unification of the existing central authorities, viz., the department of science and art, the Charity Commission (so far as it dealt with educational endowments), and the education department, in one central office, and the establishment of an educational council to advise the minister of education in certain professional matters, (2) the establishment of local authorities, to consist of committees of the county councils with co-opted elements, (3) the formation of a register of teachers with a view to the encouragement of professional training, and a system of school registration upon the basis of inspection and examination. The first of these recommendations was carried out by the Board of Education Act, 1899, and under the same act an attempt was made to give some effect to the third named object, which unfortunately fell short of success. The realization of the second, and most important, of the recommendations was deferred till 1902, when it was brought about as part of a wider reorganization of the educational system.

In 1896 an endeavour was made to meet the demands of the voluntary managers of elementary schools by means of a bill introduced by Sir John Gorst. This bill with its provision for a special aid grant to be administered by county education authorities, which were to exist side by side with the school boards, represented a kind of compromise between the system of 1870 and what later developed in 1902. It encountered opposition in all quarters and was withdrawn. In 1897, however, the position of the denominational school was strengthened by the Voluntary Schools Act, which provided for a special aid grant of 5s per head of the scholars in average attendance in these schools.

Partial effect was given to the recommendations of the Secondary Education Commission by the Board of Education Act of 1899, which united the department of science and art with the education department in one central office under the title of the board of education, with a president and parliamentary secretary, and provided for the transfer to this board of the powers of the Charity Commissioners in relation to educational endowments, also for a consultative committee, consisting, as to not less than two-thirds, of persons qualified to represent the views of university and other bodies interested in education, for the purpose of (1) framing a register of qualified teachers, and (2) advising the board of education upon any matters referred to the committee by the board. In 1902 a representative division was adopted to correspond with the three branches of education with which the board of education concerned viz. elementary, secondary and technological. Mention may also be made here of another important measure, the Elementary Education Act of 1899 which dealt for the first time, from the point of view of the state, with mental deficiency (*q*).

Education Act, 1902.—In the sphere of elementary education, this act boldly abolished the school boards and made the local authority for every form of education (below the university), the county or county borough (where the recognized authority for technical and to a limited extent, for secondary education). By putting voluntary and ordinary elementary schools on the same footing it practically made the standard of the work in the two identical and eventually built up in almost complete network of well-equipped secondary schools as well as a vigorous system of

technical education Under the impartial administration of the counties the religious question practically ceased to exist. The act was extended to London in 1903. For framing and carrying it through, special credit was due to Arthur (afterward Lord) Balfour and Sir R. Morant. Its principal provisions were as follows:

Part I. Local education authority. The council of every county and of every county borough was the local education authority for higher and elementary education, for the purpose of elementary education autonomous powers were conferred upon boroughs with a population of more than 10,000, and urban districts with a population of more than 20,000.

parishes benefited any expenses incurred in regard to education other than elementary.

Endowments.—The act introduced a new principle into the administration of endowments by directing that their income, so far as necessarily applicable for those purposes of a public elementary school for which the local authority were liable, be paid to that authority for the relief of the parochial rate.

A number of Nonconformist ratepayers refused to pay the education rate on the ground that their consciences forbade their supporting the religious teaching in denominational schools, and their willingness to become subject to distraint and consequent inconveniences rather than pay the rates became the foundation of a widespread political campaign known as "Passive Resistance." In Wales, where in the rural districts the schools were commonly Anglican while the population was Nonconformist, particular difficulties arose in administering the act in consequence of the hostile attitude of the county authorities. Accordingly the government passed the Local Education (Local Authority Default) act, 1904, empowering the board of education, in the case of default by the local authority, to make payments direct to the managers of the school and to deduct the amount from the sums payable to the defaulting authority.

Supplementary Bills.—When the Liberal party came into power again in 1906, Augustine Birrell, as president of the board of education in Sir Henry Campbell Bannerman's administration, introduced a bill to amend the Education acts, 1902-03 with the object of securing full public control of all rate-aided schools and the appointment of teachers without reference to religious belief. The bill encountered strong opposition from Anglicans and Catholics, it passed the house of commons by a large majority, but after unavailing attempts at compromise upon the amendments introduced in the house of lords, the two houses failed to agree and the measure was lost.

Early in the session of 1908, Reginald McKenna introduced a bill containing a scheme for a new system of allocating the parliamentary grant, and proposing to make Cowper Temple teaching compulsory in all aided schools. The bill was remodelled by his successor, Runciman, but in spite of negotiations with the Church party, no compromise was reached, and the bill was ultimately withdrawn by the government when in committee of the house of commons.

The Education (Provision of Meals) act, 1906, enabled local education authorities to aid voluntary agencies in the provision of meals for children attending public elementary schools, and in certain cases with the consent of the board of education to defray the cost of the food themselves.

In 1907 an uncontroversial act entitled the Education (Administrative Provisions) act, besides dealing with various matters of technical and administrative detail, laid upon local education authorities the new duty of providing for the medical inspection of all children attending public elementary schools. In connection with this act the board of education established a medical department to advise and assist them in supervising local education authorities in carrying out their statutory duties in this regard. The whole department was significant of the new sense of the importance of hygiene and physical training.

Other noteworthy developments were the extension in the provision for mentally and physically defective children (*see* BLIND, TRAINING AND WELFARE OF THE, DEAF AND HARD OF HEARING, EDUCATION OF, MENTAL DEFICIENCY, etc.), and a more definite organization of "after care" work, including the finding of employment for pupils on leaving school. The act of 1902, by placing secular education in public elementary schools under the control of strongly organized local education authorities, enabled the board of education in the code of 1904 to abolish the last traces of the system of payment by results, by setting forth "a properly co-ordinated curriculum suitable to the needs of the children, with an indication of the relation which the various subjects of instruction should bear to each other, in place of the relatively haphazard list of possible branches of knowledge which were formerly presented to the choice of individual schools or authorities." In the new code also the board for the first time endeavoured to state for the guidance of teachers and parents the

them. Assistant teachers and pupil teachers might be appointed in voluntary schools "if it is thought fit" without reference to religious creed and denomination, where there were several candidates for the post of pupil teacher, the appointment was to be made by the L.E.A.

Provision of New Schools.—New schools might be provided either by the L.E.A. or any other persons, subject to the issue of three months' public notice, and to a right of appeal on the part of the managers of any existing school, the L.E.A. (in the case of proposed voluntary schools) or any ten ratepayers of the district, to the board of education on the ground that the proposed school was not required. Any enlargement of a public elementary school which in the opinion of the board of education was such as to amount to the provision of a new school, and any transfer of a school to or from the L.E.A. had to be treated as the provision of a new school. In deciding appeals, the board was to have regard to the interest of secular instruction, the wishes of parents as to the education of children, and the economy of the rates, but existing schools were not to be considered unnecessary if the average attendance was not less than 30.

Aid Grant.—Section 10 provided a new aid grant payable to the L.E.A. for the number of scholars in average attendance in schools maintained by them.

Education Committees.—All councils having powers under the act, except those having concurrent powers as to higher education only, were to establish education committees in accordance with schemes approved by the board of education. All matters relating to the exercise by a council of their powers under the act, except the power of raising a rate or borrowing money, stood referred to the education committee. Every scheme had to provide (1) for the appointment of a majority of the committee by the council, the persons so appointed to be already members of the council unless the council otherwise determine, (2) for the appointment by the council of persons of experience in education, and of persons acquainted with the needs of the various kinds of schools in the area of the council, (3) for the inclusion of women.

Expenses.—All parliamentary grants were made payable to the L.E.A. instead of, as previously, to the managers. The county council was to charge a proportion of all capital expenditure and liabilities, including rent, on account of the provision or improvement of any public elementary school, on the parish or parishes served by the school, such proportion to be not less than one-half or more than three-fourths as the council thought fit. The county council might also charge on the

proper aim of the public elementary school laying stress upon that element of the training of character which the system of payment by results had obscured. The new spirit was strikingly manifested in the volume of *Suggestions for the Consideration of Teachers*, issued by the board of education in 1905. Apprehension of the true aims of elementary education led to a corresponding development of instruction of a practical character, observation lessons and nature study being treated as a necessary element in the curriculum, while handicraft and gardening and domestic subjects (for girls) were encouraged by special grants. Increased attention was bestowed both by the central and local authorities upon the problem of rural instruction (see RURAL EDUCATION).

According to the official returns for 1907-08, the total number of scholars on the registers was as follows: council schools 2,991,741, voluntary schools 2,566,030, total 5,557,771, and the total attendance upon which grant was paid was 4,928,659. The percentage of actual average attendance to average number on the registers was 88.50%. The parliamentary grant (England and Wales) for elementary schools, other than higher elementary, amounted to £11,023,433.

A large number of the old higher grade board schools (declared illegal under the Elementary Education acts by the judgment in the case of *Rev v Cockerton* in 1901 and legalized temporarily by an act passed for the purpose in the same year) were converted into municipal secondary schools under the act of 1902. In the succeeding years provision was made in the code for higher elementary schools of a specialized and technical type intended only for industrial districts. In 1906, as the result of the recommendations of the consultative committee, a new type of higher elementary school was admitted for children over 12, corresponding generally to the French *école primaire supérieure*, and having "for its object the development of the education given in the ordinary public elementary school, and the provision of special instruction bearing on the future occupations of the scholars, whether boys or girls" (For subsequent history, see CENTRAL SCHOOLS).

The total expenditure (exclusive of capital outlay) of the local authorities (1906-07) in England only, upon elementary education, including industrial and special schools, was £19,776,733, of which £10,408,242 was met by the ordinary parliamentary grant, and £8,930,468 was the balance required to be met by rates. The difference being represented by receipts from various sources. The average cost per child of elementary schools in England and Wales (including London) was £5 4s 10d, and the average central grant (excluding grants for special purposes) at 41s, leaving 19s to be raised locally.

Training of Teachers—The training of teachers for the two great branches of public education, elementary and secondary respectively, early became an important part of the general administrative problem. Sir Joshua Fitch pointed out that the full appreciation of the importance of training began at the lower end of the social scale. Shuttleworth and Tunnell in 1846 urged the necessity of special training for the primary teacher, and hoped to establish state training colleges, to supply this want, but the one college at Battersea which was founded as an experiment was soon transferred to the National Society (the 'National Society for educating the poor in the principles of the Established Church' founded in 1811). Before this Bell and Lancaster had made arrangements in their model schools for the reception of a few young people to learn the system by practice. The religious bodies in England, notably the established church, proceeded to avail themselves of the failure of the central government and a number of diocesan colleges for men and separate colleges for women were gradually established. In 1851 the British and Foreign School Society (founded 1808) placed their institutes at the Borough Road and Stoke Newington, London, on a collegiate footing, and subsequently founded other colleges at Swansea, Bangor, Darlington and Balfour Walden; the Roman Catholic Church provided two for women and one for men, and the Wesleyans two one for each sex. The new provincial colleges of university rank were invited by the educational department to attach normal classes to their ordinary course and to make provision for special training and suitable

practice in schools for those students who desired to become teachers. Thus the residential colleges of the old type and the day colleges attached to institutions of university rank, were both subsidized by grants from the treasury, and regularly inspected. As the need of special training for teachers became further recognized by the consideration of the same question in regard to teachers in higher and intermediate schools (Cambridge instituting in 1879 examinations for a teacher's diploma, and other universities providing courses for secondary as well as primary teachers and establishing professorships of education) the attitude of the board of education toward the problem gradually became more and more a subject of controversy and of public interest, as indicated by the clause in the act of 1899 providing for a public registration of qualified teachers and for the gradual elimination from the profession of those who were unqualified. And meanwhile the increased solidarity of the National Union of Teachers (founded in 1870), the trade union of the teachers, brought an important body of professional opinion to bear on the discussion of their own interests.

The question of preliminary education of elementary teachers reached a critical stage in 1909. The history of pupil teachership as a method of concurrent instruction and employment showed that it was, in its inception, something in the nature of a make shift, the ideal placed before local education authorities in the regulations of the board was the alternative system whereby with the aid of national bursaries (instituted in 1907) "the general education of future teachers may be continued in secondary schools until the age of 17 or 18, and all attempts to obtain a practical experience of elementary school work may be deferred until the training college is entered, or at least until an examination making a natural break in that general education and qualifying for an admission to a training college has been passed." Under the revised pupil teacher system established by the regulations of 1903, provision was made for the instruction of pupil-teachers in centres which as far as possible were attached to secondary schools receiving grants from the board of education under the regulations for secondary schools. Accordingly, the result was to modify the old system in two ways, first by providing the alternative of a full course of secondary education, secondly by associating pupil-teachership itself as far as possible with part time attendance at a secondary school (See TEACHERS, TRAINING OF).

One of the principal difficulties which confronted the state and the local authorities in their task of organizing an improved system of public education under the act of 1902 lay in the deficiency of training colleges in view of the increased number of teachers. Moreover there was a widespread feeling that the provision of training colleges should be undertaken by the state as a matter of national concern. Accordingly a new system of building grants in aid of the establishment of training colleges was instituted in 1905. In 1906 these grants were raised from 25% to 75% of the capital expenditure, but were limited to colleges provided by local authorities. A further difficulty in view of the municipalization of education arose from the fact that the majority of the residential colleges were in the hands of denominational trusts which did not admit a conscience clause. Under the presidency of McKenna (1907), the board of education in regulations which evoked much controversy, "with a view to throwing open as far as possible the advantages of a course of training in colleges supported mainly by public funds to all students who are qualified to profit by it, irrespective of religious creed or social status," laid down that the appointment of a candidate might in no circumstances be rejected on any religious ground, nor on the ground of social antecedents or the like. The same regulations provided that no new training colleges would be recognized except on terms of compliance with certain conditions as to freedom from denominational restrictions or requirements. The obligation as to religious exemptions was limited to 20% of the admissions.

Training facilities for secondary teachers entrusted at Cambridge as far back as 1890, and the other universities later followed suit. None the less, progress was far slower than in the elementary sphere, especially in regard to the men. Many headmasters, especially in the public schools still believed that the best

way was for the young master to play himself in. With the head mistresses, on the other hand, training was more and more regarded as a *sine qua non*. It is only fair to add however, that even with the men the pace accelerated.

The fear that a considerable part of the national expenditure upon elementary education was wasted for want of an effective system of continuative instruction to be given out of working hours to adolescents engaged in industrial employment led to an inquiry by the consultative committee of the board of education whose report (1909) recommended a reduction in the size of classes in elementary schools by the new staffing regulations of that year, an increase in handwork with a view to rendering the curriculum less bookish and more efficient as a training for industrial and agricultural life, and legislation to reform the system of half time attendance and raise the age of compulsory attendance to 13 and ultimately 14. They further recommended a super structure of continuative schools or classes at which attendance would be compulsory up to 17 under bylaws adoptive locally at the option of the local education authorities. In 1906-07 about 21 per thousand of the population of England and Wales attended evening schools and classes inspected by the board of education, and grants amounting to £361,596 were paid for 440,718 regular attendants. (See CONTINUATION SCHOOLS.)

The general progress in elementary education, great as it was in the years following the act of 1902, had been outstripped by that made in secondary education. During that period there had been built up a liberal system of local scholarships and free places, amounting after 1907 to 25% or more of the pupils actually in the schools, providing a ladder from the elementary school to the secondary and thence to the university, including, as it has been shown the majority of future elementary teachers. In addition scales of salaries had been introduced by many local authorities, the curriculum rendered far more flexible by the abolition of regulations, the school life lengthened, and an imposing, though still incomplete, network of schools developed throughout the country. By 1910 there were on the board of education's grant list, 841 secondary schools with 141,749 pupils, while in addition 87 schools were recognized as efficient, but received no grant.

1910-14.—The period of 1910-14 was one of steady progress in education even if somewhat uneventful from the parliamentary point of view. One noticeable matter in that sphere was the Elementary Education act of 1914 which renewed the act of 1899 (Defective and Epileptic Children) in a more drastic form. Another landmark was the board's circular on physical exercises in secondary schools, in which Swedish exercises were definitely laid down as the official form of physical training, similar recognition having already taken place in elementary schools and training colleges. But, in view of subsequent history, perhaps the most important event was in the realm of university education when in 1913 the report of the royal commission on London university (q.v.), presided over by Lord Haldane, was issued, the commission having been appointed in 1907. One part of the report seriously threatened the existence of the external degree, a danger later averted, but a still more important part of it dealt with the revision of the organization and government of the university, which formed the groundwork of a subsequent commission and parliamentary action.

World War I.—During the period of World War I all grades of work suffered. The elementary schools lost many of their teachers, who were called on for military service. The men's training colleges were seriously depleted, and several were closed or amalgamated, while in the later stages of the war, the boys' secondary schools lost practically all their pupils at the age of 18. A large amount of the teaching was done by women who occupied positions usually held by men teachers. Nevertheless, there was progress to chronicle. In 1917 the board, which in 1914 had abolished all examinations for lower and middle forms in secondary schools, established the secondary schools council for co-ordinating the standards of the remaining examinations in these schools, multiplicity of examinations, with considerable variety in standard, having been in the past a serious flaw in English education. (See EXAMINATIONS.)

Education Acts 1918 and 1921.—The men who returned from the front on the conclusion of the war had realized the need of education as a *sine qua non* to promotion from the ranks. At the same time there had been forming a home strong body of opinion in favour of insuring, as far as possible against the inevitable aftermath of postwar unemployment. This opinion may be said to have focused around the report of the departmental committee on juvenile education in relation to unemployment which, appointed in 1916 reported in 1917, many of its suggestions being embodied in the bill of 1918.

The Education act of 1918, which was carried through by H. A. L. Fisher, and which was re-enacted, with most of the earlier acts, in consolidated form by the Education act of 1921, made a determined attempt to improve the state of things in England and Wales. It aimed at the establishment of "a national system of public education available for all persons capable of profiting thereby," and the local authorities were called on to prepare schemes setting out the provision which they had made and proposed to make to this end. The act effected important changes in regard to elementary education (see ELEMENTARY EDUCATION), including the power to establish nursery schools (q.v.) for children between two and five years of age. It raised the compulsory school age from 12 to 14 with power to the local authority to extend that age to 15. It abolished part-time attendance, made provision for central schools for the older and more intelligent children in the elementary schools, and laid emphasis on physical training, enlarged facilities for recreation of all kinds and the social side of education. The local authorities were to co-operate in providing for the preparation of children for further education in schools other than elementary, and for their transfer at suitable ages to such schools. The act also dealt with the supply and training of teachers, and extended the duties and powers of the local authorities with reference to medical inspection and mental deficiency and treatment, to secondary and continuation schools. It removed the limit imposed on rating powers for education other than elementary.

But perhaps the most novel feature of the statute was that which instituted a compulsory system of part time education after the close of the elementary school period. Young persons, between the ages of 14 and 18, were required to attend a continuation school for 320 hr. in the year, unless able to claim exemption under the act. (See CONTINUATION SCHOOLS.) Other movements that grew out of this legislation, or received an added momentum from its presence on the statute book, were the Workers' Education association and the movement for adult education (q.v.).

In 1920, for the first time in the history of English education, a national scheme of salaries for elementary and secondary teachers (see SECONDARY EDUCATION) was established under the chairmanship of Lord Burnham, known thereafter as the Burnham scale. Slight modifications were subsequently made in both pension and salary schemes, but the general result of these reforms was to place the position of the teacher on a satisfactory footing, one direct outcome being the rapid growth of members on the teachers' register that followed, largely through the efforts of the National Union of Teachers. In 1920, also, the board started state scholarships to enable the talented children of parents with limited means to proceed to the university. Dropped during 1922-23, they were revived in 1924, and the maximum number offered in 1927 was 200. Moreover, during the same period (1918-22), the board published four reports of committees on modern languages, science, classics and English. In 1922 the board issued a valuable circular on the possibility of co-ordinating the recommendations made in these reports with the claims of other subjects.

After 1922 education went through a period of slowing down and consolidation, while at the same time a large amount of official investigation and research took place. The financial uneasiness may be said to have started with the seventh report of the Select Committee on National Expenditure in 1920 which specially dealt with national education. But the actual financial stress did not make itself felt until 1922 when, with almost dramatic suddenness, unemployment, hitherto at an insignificant figure, bounded

up in less than six months to an abnormal height. Among educational developments the scheme for universal day continuation schools (1907) was the first to suffer. Unfortunately conceived as the prolongation of a general education they became speedily unpopular with the pupils, parents and the general public. Practically the only schools that survived were the London ones. A certain number of these were saved by being placed on a voluntary basis with a voluntary staff and as such became increasingly popular.

In spite of the financial crisis elementary schools, secondary schools, universities and technical institutes of all kinds held their ground and even progressed though in elementary education, because of the falling off in the juvenile population from war causes, the number of pupils showed a considerable decrease. In secondary schools the numbers did not decline and there was a substantial increase in the number of pupils over 16 and in those doing advanced work. The Burnham scale was extended to technical institutes. (For the history of English universities during this period see *UNIVERSITIES*.) (C. Br., X.)

Developments Preceding and During World War II—The Education Act, 1916, provided for the raising of the age of compulsory education from 14 to 15 years, though with exemption at 14 for "beneficial employment." The reorganization of the public elementary school into separate primary (5-11 years) and senior (11-14) divisions was given fresh impetus by this act and some fine senior schools were built or projected. A national campaign for physical education brought to a climax by the Physical Training and Recreation act, 1918, is in full swing. A nation wide modernization of technical education involving a capital expenditure of 14,000,000 is being planned.

Despite these signs of progress, the teachers were uneasy and apprehensive. The buildings in which many had to work were out of date and not infrequently in bad repair. Their pay was poor and their status in society equivalent. Thousands of classes were far too large. The secondary school curriculum had in the endeavour to meet modern requirements become a congested mass of unrelated subjects. The clauses in the 1936 act exempting children from attendance at school after 14 if they found "beneficial employment" were felt to be a retrograde step.

These and other complaints gave rise to a feeling largely inarticulate that nothing less than a complete reorganization of the statutory system of education was necessary. The publication in Dec. 1938 of the report of the consultative committee of the board of education on *Secondary Education, with Special Reference to Grammar Schools and Technical High Schools* (the Spens report) gave considerable impetus to this feeling. Thus, like the committee's earlier report on *The Education of the Adolescent* (the Hadow report, 1926), recommended that all varieties of post primary education should be regarded as secondary education, and suggested, more controversially, that this education should be conducted in three main types of secondary school: grammar, technical and modern—thus opening a wide dispute.

But by early 1939 reform projects were overshadowed by the gathering threat of war. School children were doing gas mask and evacuation drill, administrators preparing estimates for air raid shelter. On Sept. 1, 1939—the day the school leaving age was to have been raised to 15—the Germans invaded Poland and Britain began to evacuate children from her 140 large centres of population. With in 11 days, 750,000 school children and many thousands of younger ones were transported into war-torn districts. As no bombing occurred, great numbers quickly returned home, but Christmas, more than a half were back. During the months the public system of education was gravely disorganized but by the great efforts of administrators, teachers and voluntary helpers order was restored. When heavy bombing began in Sept. 1940 the educational services were generally so well prepared that they could elude or improvise successfully if a moment's notice.

While the authorities were coping with the chaos caused by evacuation, three movements of profound social significance had their birth. In Nov. 1939 the go onment founded the service of youth by calling into partnership the local education authorities and the national voluntary youth organizations and offering

generous money grants in aid of their joint efforts to provide educational social and recreative facilities for young people beyond compulsory school age. Within three years in organized network of provision had covered the country and the youth service thus created by the end of World War II had become an integral part of the public system of education.

A complex of discontents brought to the surface mainly by evacuation and including significantly, widespread anxiety on the part of parents about their children, gave rise early in the war to a demand—which spread rapidly—for radical and far reaching reforms in the public system of education. The board of education was not slow to take cognizance of this and in 1941 circulated to interested bodies a comprehensive questionnaire. During the following 18 months or so it received in answer more than 100 detailed memorandums. Most of these were published in pamphlet form or noted in the press, and public interest was further aroused and focused by numerous public meetings held all over the country notably by the Council for Educational Advance formed in 1942 by the Trades Union congress, the National Union of Teachers, the Workers' Educational Association and the Co-operative society.

Education Act 1944—R. A. Butler who had become president of the board of education in July 1941, immediately entered into discussions with the numerous interests concerned with public education in England and Wales and exactly two years later, after prolonged negotiations conducted by him, presented to parliament the government's policy for postwar reform in a White Paper entitled *Educational Reconstruction*. In Dec. 1943 he introduced into parliament a bill to reform the law relating to education in England and Wales and on Aug. 4, 1944, this became law as the Education act, 1944.

This great act, the bulk of which came into operation on April 1, 1945, remodelled the public system of education by abolishing the previous division into elementary and higher education and organizing it in three progressive stages: primary (to age 12), secondary (12-18) and further, from the end of compulsory full time education onward, and by making it the statutory duty of the local education authorities to secure the provision of efficient education throughout the three stages (previously the provision of elementary education only was a duty). The president of the board of education who could only "superintend" was made a minister with power to direct and control the authorities. The act raised the age of compulsory full time education, first from 14 to 15, and later to 16, as soon as practicable. It established a system of compulsory part-time education (one day a week) up to age 18 for all not in full time education.

Tuition fees were abolished in primary and secondary schools maintained by the public authorities. All private schools were to be registered and inspected. *See also* *EDUCATION, HISTORY OF*.

For a full and complete supply the required extra accommodation (H. C. D., X.)

SCOTLAND

The Education (Scotland) act of 1872 set up elective school boards and vested in them the existing parish and burgh schools. A conscience clause, allowing exemption from religious instruction, did little more than confirm existing usage. The school boards were left full liberty as to the religious instruction to be given in their schools, and in practice school boards universally adopted the Shorter Catechism, which was acceptable to all denominations of Presbyterians. The act made the school boards responsible for the supply of school accommodation, and introduced compulsory attendance. By the act of 1901 the age of

EDUCATION, HISTORY OF

compulsory attendance was raised to 14, with provision for exemption after 12.

A notable feature, historically, in Scottish education was the extent to which the parish schools supplied their best pupils with higher education. Administrative changes under the code of 1903 and later codes led to a remarkable development of higher-grade schools and departments, organized upon the lines of the higher primary schools of France "to continue a stage further," said the report of the Scottish education department, "the general education of that considerable body of pupils who, under new conditions, may be expected to remain at school till 15 or 16."

There was a gradual abandonment of individual examination as the basis for the payment of grants. Elementary education was generally rendered free by the fee grants under the parliamentary vote, and by the sums accruing under the Local Taxation (Customs and Excise) act of 1890 and the Education and Local Taxation (Scotland) act of 1892.

The Act of 1908—Certain additional powers were conferred upon school boards by the Education (Scotland) act of 1908, including powers to provide school meals, in outlying parts to provide means of conveyance, or pay travelling expenses of pupils or teachers, or defray the cost of lodging pupils in convenient proximity to a school, to provide for medical inspection, and in the case of children neglected by reason of ill health or poverty of the parent, to supply food, clothing and personal attention. Perhaps the most noteworthy provision of the act of 1908 was that which enabled (not obliged) school boards to make bylaws requiring attendance at continuation classes up to the age of 17. It laid upon the school boards the duty of making suitable provision of continuation classes in the crafts and industries practiced in the district.

The Scottish Education act of 1872 distinguished certain burgh and parish schools as "higher class public" or secondary schools. The act of 1908 dealt in some detail with secondary education. Secondary schools were distinguished from intermediate, the former being defined as providing at least a five-year course, the latter as providing at least a three-year course for pupils who had reached a certain standard of attainment in elementary subjects. Intermediate schools were later abandoned and a three-year advanced course from the ages of 12 to 15 was provided at primary schools, leading to the higher day school certificate. A two-year advanced course led to the lower day school certificate. The teaching in these advanced courses was partly practical, but included also morals and citizenship, music, drawing, English, science, mathematics and physical exercises. It was the aim of the authorities to staff the advanced divisions with teachers as highly qualified as those in secondary schools. A qualifying test at the age of 11 or 12 decided whether a child was to enter an advanced course or proceed to the secondary school. But there were facilities for changing over at a later stage.

The Act of 1918—By the Education (Scotland) act of 1918 the machinery of the system of education was reorganized, with a large increase of expenditure, both national and local, which was partly due to the transfer of voluntary schools to the public authorities. A scale of minimum salaries for teachers was drawn up in 1919. In 1920 the education department urged rigid economy, and there followed a reduction in salaries and staffs and an increase in the size of classes. In 1924 the restrictions were relaxed and there was a noticeable increase in educational activity, but in 1925 the urge for economy was again dominant.

The 1918 act swept away the system of parochial school boards. Five large burghs, Edinburgh, Glasgow, Aberdeen, Dundee and Leith, remained separate educational areas (the number was reduced to four by the amalgamation of Leith with Edinburgh in 1920), elsewhere the area is the county, including the burghs within its bounds. Electors to the education authorities were registered local government electors, and voting was conducted on the principle of proportional representation. School management committees, composed of representatives of the education authorities, parents, teachers, and others nominated by local bodies, had limited powers under the education authorities.

Education authorities were required to provide free primary,

intermediary and secondary education in all districts, but they could maintain a limited number of fee-paying schools and make grants to others. No pupil, however, could be debarred from continued education by inability to pay fees, and each education authority has a bursary scheme. They were also empowered to spend money on the provision of food and books for the children, and to give assistance to qualified persons attending the university or training college.

Nearly all the voluntary or denominational schools were transferred to the education authorities in accordance with the act, the teachers in such schools were appointed by the education authority after being approved, with regard to character and religious belief, by the denomination concerned. No child whose parents objected to his receiving religious instruction was thereby to lose any other advantage of the school. Voluntary schools not transferred to the education authority ceased to be eligible for grant from the education fund. A national committee for the training of teachers, established in 1920 and elected by the education authorities, controlled the former denominational training colleges.

The Act of 1945—The Education (Scotland) act, 1945, generally applied to Scotland the provisions of the English Education act of 1944 (see above). (M G G, X)

UNITED STATES

Religious Origin of Schools—Schools of America, as with the older European countries from which the early American settlers came, arose as children of the church. From instruments of religion they gradually changed into instruments of the state. The first schools in America were clearly the fruits of the Protestant revolts in Europe, and were set up by dissenters who had come to America to obtain a freedom in religion which they could not enjoy in their own lands. The reformers had insisted upon the necessity of a knowledge of the Gospels as a means to personal salvation, and the ultimate outcome was the creation of schools to teach children to read. The early settlers in New England brought these ideas with them, and one of their first interests, after they had built their homes and churches and settled the civil government, was the creation of schools and a college to advance learning in the new land and to provide a supply of literate ministers. With practically all the early religious groups that settled in the central and northern colonies the education of the young for membership in the church, and the perpetuation of a learned ministry for the congregations, elicited serious attention. Only in the Anglican colonies of Virginia and southward was this early interest in education largely lacking.

Three Attitudes—From the European background of the early colonists three attitudes toward education were established in the American Colonies. These are of importance because they materially affected the development of education in the states during the early national period. The first was the compulsory-maintenance attitude of the Puritans of the New England colonies, who set up a combined religious and civil form of town government and by colony legislation in 1642 and 1647 established schools and ordered children to be taught to read and to be given instruction in religion. Still earlier (1635) the beginnings of an English type of Latin grammar school had been made at Boston, and the year following (1636) an English type college (Harvard) had been established by the same people at Cambridge, Mass. The laws of 1642 and 1647 are important, in part because for the first time in the English-speaking world a legislative body representing the state made education compulsory, and also because what the Calvinistic Puritans of Massachusetts established in practice was later generally adopted by the different American states. This distinctively Calvinistic contribution to the new-world life was one of large future importance.

The second attitude was what became known as the parochial-school attitude, and was best represented in Pennsylvania. Unlike New England, no sect was in the majority in Pennsylvania, and church control by each denomination rather than general colonial action resulted. There was no appeal to the state. Instead, parochial schools were established in connection with the churches

and private day schools were opened in the larger towns. Under the primitive conditions of the time the interest even in religious instruction often declined almost to the vanishing point, and Pennsylvania and the other middle colonies finally settled down to the policy of leaving education to such private and parochial schools as cared to undertake it, a policy that was overcome later only after long and stubborn resistance.

The third attitude was what was known as the pauper school nonstate interference attitude, and was best exemplified by Virginia and the southern colonies. Unlike New England these had been settled by English who had come to America for gain rather than for religious freedom, and the lack of any strong religious motive for education naturally led to the continuation of English practices rather than development on distinctively colonial lines. The tutor in the home education in small private and select day schools, or education in the mother country for the sons of the well-to-do planters, with apprenticeship training and a few pauper schools for the children of the poorer classes consequently came to be the prevailing system, and as in the mother country education was not considered the business of the state, nor did the church give any special attention to it. As a result in Virginia, and the colonies which followed its example, the English charity school idea came to dominate such general education as was provided, with the apprenticing of orphans as a prominent feature.

The 17th century was a period of the transplanting of European ideas as to government, religion and education to the new American Colonies and by the 18th century the three attitudes toward educational responsibility had been clearly established on American soil deeply influencing subsequent American educational development. In time the first or New England Calvinistic attitude came to be the accepted American conception, and the other two types were subordinated or eliminated. Almost all the early 19th-century struggles to establish education in the states were battles between the upholders of these different attitudes.

Change in Character.—During the 17th century little or no attempt at adaptation or change in English ideas transplanted to the colonies was made. With the coming of the 18th century there was a waning of the old religious interest, a tendency to create native institutions instead of copying those of the mother country, the rise of a civil as opposed to a religious form of government, new interests in trade and shipping, a breakdown in the old aristocratic traditions and customs, and a dawning individualism—all of which tended to weaken the hold of the old religious influences and in turn the interest in the old type of schools and learning. By 1750 the change in religious thinking had become quite marked, the New England religious town had begun to disintegrate, and a native type of district school and academy had arisen to threaten the very existence of the town grammar school. By 1750, too, it was clearly evident that European traditions and ways, manners and social customs, and types of schools no longer satisfied. To the north this expressed itself in a tendency to modify all established educational institutions to make them conform more closely to American thinking, to the south in a tendency to discard schools altogether. There were many evidences, in education as in government, that the end of the colonial period was near at hand and the Revolutionary War came as the culmination of a process of evolution which had been taking place for some time.

Effect of the American Revolution.—With the outbreak of the war education everywhere suffered seriously. Most of the rural and parochial schools closed or continued a more or less intermittent existence. In some of the cities and towns the private and charity schools continued to operate, but in others they were closed entirely, for the war engrossed the energies and resources of the people of the different colonies. In New York city then the second-largest city in the country practically all schools closed with British occupancy and remained closed until the end of the war. The Latin grammar schools and academies often closed from lack of pupils, while the colleges were almost deserted, Harvard and Kings, in particular, suffered grievously, and sacrificed much for the cause of liberty. The period from the revolution to the beginning of the national government (1775-89) was

a time of rapid decline in educational advantages and increasing illiteracy among the people. Meagre as had been the opportunities for schooling before 1775, by 1790, except in a few cities and in the New England districts, they had shrunk almost to the vanishing point.

A Half century of Transition.—The first half century of America's national life may be regarded as a period of transition from the church control idea of education to the idea of education under the control and support of the state. It required time to make this change. Up to the period of the beginnings of national development education had almost everywhere been regarded as an affair of the church, somewhat akin to baptism, marriage, the administration of the sacraments and the burial of the dead. Even in New England, which formed an exception, the evolution of the civic school from the church school was not yet complete. A number of new forces—philanthropic, political, social, economic—now combined to produce conditions which made state rather than church control and support of education seem both desirable and feasible. The rise of a new national government based on the two new principles of political equality and religious freedom together with the rise of new economic conditions which made some education for all seem necessary for economic as well as for political ends, changed this age old situation.

For long the churches made an effort to keep up, as they were loath to relinquish their former hold on the training of the young. The churches, however, were not interested in the problem except in the old way, and this was not what the new democracy wanted. The result was that, with the coming of nationality and the slow but gradual growth of a national consciousness, national pride, national needs, and the gradual development of national resources in the shape of taxable property, all alike combined to make secular instead of religious schools seem both desirable and possible to a constantly increasing number of citizens. This change in attitude was facilitated by the work of a number of semiprivate philanthropic agencies, the most important of which were (1) the Sunday school movement, (2) the growth of city school societies, (3) the Lancastrian movement, and (4) the coming of the infant school societies.

Of these the Lancastrian movement was by far the most important because it, for the first time, made general education for all seem financially possible. All at once, comparatively, a new system of teaching had been evolved which not only improved but at the same time tremendously cheapened education. The new Lancastrian schools materially hastened the coming of the free school system in all the northern states by awakening thought, provoking discussion and accustoming the people to bearing the necessary costs which public education entail. The city school societies, privately organized associations to provide educational facilities in the cities, formed a connecting link between the Lancastrian schools and the publicly organized schools which followed.

Creation of the U S State School.—By the close of the first quarter of the 19th century a great struggle for the creation of a series of tax-supported, publicly controlled and directed, and non-sectarian common schools was in progress, and the second quarter of the century may be said to have witnessed the successful conclusion of the battle. In 1825, always excepting certain portions of New England where the free school system had become thoroughly established such schools were only the distant hope of state men and reformers, in 1850 they were becoming an actuality in every northern state. The 25 years intervening marked a period of public agitation and educational propaganda, of many hard legislative fights, of a struggle to secure desired legislation and then to hold what had been secured, of many bitter contests with church and private-school interests, which felt that their vested rights were being taken from them, and of occasional referendums in which the people were asked, by vote at the polls to advise the legislature as to what to do. Excepting the battle for the abolition of slavery, perhaps no question had ever been before the U S people for settlement which caused so much feeling or aroused such bitter antagonisms.

To meet the arguments of the objectors, and to change the opin-

EDUCATION, HISTORY OF

ions of a thinking few into the common opinion of the many, to overcome prejudice, and to awaken the public conscience to the public need for free and common schools was the work of a generation. It was likewise the work of a generation to convince the masses that the scheme of state schools was not only practicable but also the best and the most economical means of giving their children the benefits of an education, to persuade propertyed citizens that taxation for education was in the interest of both public and private welfare, to show legislators that it was safe to vote for school bills, and to overcome the general opposition caused by apathy, sectarian jealousy and private interests. In time, however, the desirability of common free tax supported nonsectarian state controlled schools came to be evident to a majority of the citizens of the different U. S. states, and as it did so, the American state school free and equally open to all, was finally evolved and took its place as the most important influence in the national life working for the perpetuation of U. S. democracy and the advance ment of the public welfare.

The Struggle for Public Schools—The problem confronting those interested in establishing state controlled schools was not the same in any two states though the struggle in many states possessed common elements, and hence was somewhat similar in character. There were six strategic points in the struggle, which may be described briefly, as follows:

1 *The Battle for Tax Support*—Land endowments, lotteries, licence taxes, and rate bills were the favourite early means for raising money for school support. The land endowments made by the early states and by the federal government to the new western states were looked upon as having large potential values. The early idea was that the income from such sources would in time entirely support the necessary schools. Later this idea had to be abandoned when it was seen how little yearly income these sources produced, and how rapidly the population of the country was increasing. By 1825 it was evident to the leaders that the only safe reliance of a system of state schools lay in the general and direct taxation of all property. The cry that "the wealth of the state must educate the children of the state" now became a watchword, and by 1825 to 1830 the battle for direct taxation for education was joined in all the northern states except the four in New England where the principle had long been established. The struggle was a prolonged and bitter one. "Campaigns of education" had to be prepared for and carried through. Often those in favour of taxation were fiercely assailed and even at times threatened with personal violence. Indiana and New York were the critical battlegrounds, and referendums were taken. In Kentucky a long fight was waged to prevent misappropriation of the school fund and to secure a two mill (one fifth of a cent in U. S. currency) tax. The right of the state to tax for education and to compel the duplication of state aid by local taxation was seen to be the key to the whole problem of the creation of a state school system of public instruction. When this key position had been won, as it had been generally in the north by 1850, the process of evolving an adequate state school system became merely that of the further education of public opinion to cover the new educational needs. The development followed different lines in different states, and probably no two states stood at the same point in the evolution of a system of school support. Everywhere, though, the New England idea of state support was accepted, and the New England co-operative-maintenance attitude was established as the common practice of the different states. New England Puritanism here made one of its greatest contributions to American life.

2 *The Battle to Eliminate the Pauper-School Idea*—The history of the pauper school idea was in the old central and northern states made no headway in the north and in the middle west would not tolerate it. It is found on one side of the old historic conservative classes, the active taxpayers, the supporters of church school, and the proprietors of private schools. Large numbers of those in favour of pauper schools were in tendency would not brand themselves as pauper by sending their children to them, and those who accepted the div. school notion for the sake of their children, despised the system. Finally the

battle to eliminate the pauper school idea began in Pennsylvania in 1834 and in New Jersey in 1838, and in each state a victory was won and a state system of schools created only after bitter fights in the legislature and at the polls. The idea continued some time longer in Maryland, Virginia and Georgia and at places in other southern states but finally disappeared in the south with the establishment of state taxation and with the educational reorganizations following the American Civil War. The rate bill, a per pupil charge levied on parents to supplement the public funds, lingered a little longer, the cities did away with it first, and by 1871 it had disappeared from every northern state and the schools of the nation were tax supported and entirely freed from the pauper taint.

3 *The Establishment of Supervision*—The battle for taxation for education was also indirectly a battle to establish some form of state oversight for the hundreds of systems which had grown up in each of the states. The acceptance of state aid inevitably meant a small but gradually increasing state control. To exercise this control found the states creating a series of school officers to represent the state, the enactment of laws extending state control, and a struggle to integrate, subordinate and reduce to some semblance of a state school system the great numbers of small community school systems. The pivotal states in this struggle were Massachusetts, Connecticut, New York, Ohio and Michigan, and the pivotal point in the struggle was the attempt to control the local systems of school organization which had developed and spread with time. In most states the district system had run rampant, and an exaggerated idea as to district rights, district importance and district perfection had become common. In Massachusetts, New York and Indiana, in particular, such systems had almost destroyed the schools. The Massachusetts law of 1826, requiring each town to appoint a town school committee to control the schools, the establishment in 1834 of the state school fund, and the creation in 1837 of the celebrated Massachusetts state board of education with an appointed secretary—a position held by Horace Mann for 12 years—marked the culmination of the struggle in that state. Connecticut provided for a somewhat similar board in 1839, and Henry Barnard became the first secretary. Michigan and Ohio provided for a state superintendent of public instruction in 1837, and the other states soon followed these examples. From then on state supervision came to be regarded as an established principle, the work of the future being largely an elaboration of the work of Mann in Massachusetts and Barnard in Connecticut—two men who may be said to have created state supervision in the United States.

4 *The Elimination of Sectarianism*—As long as there was little intercourse and migration, and the people of a community remained fairly homogeneous, it was perfectly natural that the common religious faith of the people should enter into the instruction of the school. With the coming of foreign immigration, which began to be marked after about 1825, and the intermingling of peoples in the cities, religious uniformity ceased to exist. As necessity compelled the state to provide education for the children, sectarian differences made it increasingly evident that the education provided must be nonsectarian in character. The secularization of education in the United States thus came about as an unavoidable incident in the development of government among a people, and not as either a deliberate or wanton violation of the rights of the church. The change to nonsectarian schools came gradually. Beginning early in U. S. national history and in a way a sequel to a waning interest in religion, it was not until the 1840s that the question became at all acute. Then the fight was precipitated in both New York and Massachusetts at about the same time, and with about the same results. Finally, to settle the question, state after state amended its constitution to forbid any division or diversion of the public school fund, and each new state when admitted made similar provision.

5 *The Establishment of the High School*—The schools established by the early states were almost entirely elementary, or the so called common schools. The next struggle came in an attempt to extend the public school system upward so as to provide a more complete education than the common schools afforded.

The academy development, beginning about the middle of the 18th century (see **SECONDARY EDUCATION**) had created a new type of secondary school that was semipublic in control and more democratic in character than the town Latin grammar schools had been, and the development of the academy was marked during the first half of the 19th century. In particular, this institution offered a much broader course of study than did the Latin grammar schools, often was open to girls as well as boys, and aimed to prepare for practical life and for teaching instead of merely for college. One result of this development was a demand that the cities should establish free higher schools of a somewhat similar nature. In 1821 Boston created what is regarded as the first U.S. high school, and in 1827 Massachusetts enacted a law requiring a high school in every town of 500 or more families, in which certain specified modern studies should be taught. In 1835 smaller towns also were permitted to establish such a school. This law marked the real beginning of the U.S. high school as a distinct institution, formed the basis of all subsequent legislation in Massachusetts, and deeply influenced development in other states.

Up to 1840 about a dozen high schools had been established in Massachusetts, and a similar number in other states. The democratic west soon adopted the idea and established high schools as cities developed and the needs of the population warranted their creation. The struggle to establish and maintain these schools which New York and Massachusetts had undergone was repeated in every new state east of the Mississippi river and north of the Ohio. One of the most important of these conflicts came in the city of Kalamazoo, Mich. This case finally reached the state supreme court of Michigan which, in 1874, handed down a decision which deeply influenced all subsequent development. It confirmed the high school as an integral part of the common school system and affirmed that the voters might provide for the support of any kind of public instruction authorized by the laws of the state. This decision ranks with the Massachusetts law of 1827 as one of the important milestones in the creation of the U.S. public high school.

6 The State University—During the colonial period of American history nine colleges had been established. Harvard in 1636, William and Mary in 1693, Yale in 1701, Princeton in 1746, Pennsylvania academy and college in 1753-55, Kings (Columbia) in 1754, Brown in 1764, Rutgers in 1766 and Dartmouth in 1769. The religious purpose had been dominant in the founding of each institution, though there was a gradual shading off in denominational control and insistence upon religious conformity after about 1750. Fifteen additional colleges were founded before 1810, though the two dozen colleges then existing did not have, all told, more than 100 professors and instructors, and not more than \$2,000,000 worth of property. All were small. No one of the 24 admitted women in any way to its privileges. Fourteen more colleges were added before 1820, after which a great period of denominational effort in the founding of new colleges began, and during the next 40 years 196 new colleges were founded in the United States. Though the federal government, beginning with Ohio in 1803, had given land to each of the new states to help endow a seminary of higher learning within the state, of the 246 colleges in existence by 1860 only 17 were state institutions.

In 1816 the legislature of New Hampshire attempted to take over Dartmouth college and make of it a state university, but was stopped from so doing, in 1819, by a decision of the U.S. supreme court which held that the charter of a college was a contract the obligations of which a legislature could not impair. The effect of this decision was to give a new impetus to the state to extend their public school system upward and to crown it with a state university. It was some time, however, before such institutions became either numerous or important. For long they remained much like the denominational colleges about them—small, poorly supported, and afflicted with denominational and political controversies. Michigan was the first of the state universities to throw off the yoke of political and denominational control. Opened in 1817 at Ann Arbor, Mich. in 1832 it had a faculty of only six, 72 students and a single course of study, but by 1860 it

had enrolled 519 students and its remarkable development as a state university had begun. During the next two or three decades most other state institutions followed its example.

The Land grant Colleges (q.v.)—In 1862 congress provided (Morrill act) for a grant of public land to each state to found a college of agriculture and mechanic arts. The grant was accepted and such an institution was created in every state, 18 states added the land-grant to their existing state universities and combined the two institutions, three of the older states (originally five) gave the grant to private institutions already established within the state, and the remainder established separate agricultural and mechanical colleges.

The financial returns from the land grants were disappointing but the educational returns were very large. Probably no aid given by the national government to the states proved so fruitful as did these grants of land, and subsequently of money, for in instruction in agriculture and the mechanic arts. New and vigorous colleges were created (Cornell, Purdue and the state universities of Ohio and Illinois were examples), small and feeble state universities were awakened into new life (Vermont and Wisconsin), agriculture and engineering were developed as new learned professions, and the states were stimulated to make larger and rapidly increasing appropriations for their universities, until the state universities largely overshadowed all but the best endowed of the old denominational colleges.

The Free Public School System—By the close of the second quarter of the 19th century, certainly by 1860, the U.S. public school system was fully established, in principle at least, in all the northern states. Much yet remained to be done to carry it into full effect but everywhere democracy had won its fight, and the American public school, supported by general taxation, freed from the pauper-school taint, free and equally open to all, under the direction of representatives of the people, free from all sectarian control, and complete from the primary school through the high school, and in the western states through the university as well, may be considered as a permanency in U.S. public policy and, with the state university, represented the crowning achievements of those who worked for a state supported educational system fitted to the needs of great democratic states. Probably no other influences had done more to unify the American people, reconcile diverse points of view, eliminate state jealousies, set ideals for the people, and train leaders for the service of the states and the nation than had the academies, high schools and colleges scattered over the land. They educated only a small percentage of the population, to be sure, but they trained most of the leaders who guided the U.S. democracy.

New Influences—Up to the close of the first third of the 19th century U.S. educational development was largely native, predicated from time to time during the colonial period by new ideas brought over from England and new plans as to organization from France. The revolution put an end to English influences, and the schools evolving afterward were those adapted to the needs of a new nation on a new continent. They were distinctly of a home-pun variety. It was not until the decade of the 1820s that educational journalism in America had its beginnings, and not until a decade later that it may be said to have got under way. The first real contact with what Europe had been doing came in 1819 through the publication in America of John Griscom's *A Year in Europe*, in which he described the schools of a number of European countries, and especially the schools and work of Pestalozzi. A few other travellers published their descriptions, and in 1835 a translation of Victor Cousin's *Report on public instruction in Prussia* was printed in New York. The influence of this volume on the new constitution of Michigan, then being formulated, was of great importance. Both Calvin Stowe's *Report on Elementary Instruction in Europe*, made to the legislature of Ohio in 1837, and Alexander Bache's *Report on Education in Europe* (1839), awakened wide interest. In 1843 Horace Mann spent some months in visiting European schools, and on his return reported at length on what he had seen.

The general results of these various observations by travellers and official Reports, extending over nearly a quarter of a century,

EDUCATION, HISTORY OF

and the work of the newer educational journals, particularly the work of Henry Barnard, were to give U S educators some knowledge of school organizations elsewhere. They especially gave strong support to the movement, already in progress, to organize the many local school systems into state school systems, subjecting them to state oversight and control, they further stimulated the movement, already well begun, to grade and classify the schools in a more satisfactory manner, they helped to inaugurate a movement for the introduction of Pestalozzian methods to replace the wasteful individual and the mechanical Lancasterian plans which had for so long been in use, and they gave material assistance to the few leaders in Massachusetts and New York who were urging the establishment by the state of professional training for teachers for the educational service.

The training of teachers had been begun in the Lancasterian model schools about 1810, but the first regular teacher training school in America was established privately in 1823 at Concord, Vt by the Rev Samuel R Hall, as an adjunct to his work as a minister. In 1827 New York state, at the instance of Gov De Witt Clinton, provided for teacher training in connection with a few of the academies of the state. The training offered in all these institutions was entirely academic, as there was in America at that time no body of professional knowledge to teach. Practice in the work was obtained by teaching during the winter in the rural schools. Hall, however, tried to tell his pupils how to organize and manage a school, and finally wrote out his ideas in a series of *Lectures on Schoolkeeping* (1829), a little volume that constituted the first professional book on teaching to appear in America in the English language. In 1835, a Dr Julius, of Hamburg, Ger., visited America and described to the Massachusetts legislature the Prussian system of elementary education and teacher training. A state wide agitation for state training of teachers followed, culminating in the opening of the first state normal school at Lexington, Mass., in 1839, followed by another at Barre the same year, and a third at Bridgewater in 1840. New York state followed with a similar school in 1844, and Connecticut and Michigan in 1849. By 1860, 12 normal schools in nine states and 6 private normal schools had been organized for the training of teachers (see TEACHERS, TRAINING OF).

About 1860, largely through Edward A Sheldon, of Oswego, N Y., the introduction of the new Pestalozzian procedures began. Within a few years visitors from near and far came to Oswego to see the work of Sheldon and his teachers. The "Oswego movement," which he inaugurated, during the two decades following almost completely reshaped elementary instruction in the better schools of the U S. The normal school came into its own, and teacher training by Oswego methods was generally adopted by educationists. Between 1850 and 1880 new subjects of study were introduced in elementary education, the teaching of the older ones was revolutionized, and a new technique—a methodology—for instruction in each subject was worked out. Where before the ability to organize and discipline a school had constituted the chief art of instruction, now the ability to teach scientifically took its place as the prime professional requisite. A new conception of the child as a slowly developing personality, demanding subject matter and method suited to his stage of progress, also replaced the earlier conception of the school. With the addition of new ideas as to the teaching of history and literature, which came in with the Herbartian theories in the 1880s, and manual training and home economics instruction, which began about the same time, the most important foreign contributions to the elementary school were made. The kindergarten (*q v*), which reached the U S in the '70s and became well established by the '90s, also should be mentioned among the material contributions from foreign sources.

By 1900 the centre of gravity had been shifted from the subject matter of instruction to the child to be taught. The school, as consequence, had begun to change from a place where children prepare for life by learning certain traditional things to a place where children live life and are daily brought into contact with such industrial, social, community and real life experiences as will best prepare them for the harder problems of living which lie just ahead. These changes in character and purpose were largely

due to the teachings of John Dewey.

Expansion of the High School.—Though dating from 1821, the public high school up to about 1860 had made little headway except in regions where New England people had gone. The Civil War checked development for two decades, but after about 1885 a rapid growth took place. The old academies were replaced and the high school became the accepted U S secondary school. Along with this rapid development—in number of schools, teachers and students—a marked change in the high school itself took place. The course of study, up to about 1860 essentially a uniform book-study course of three years, after about 1880 was expanded so rapidly by the introduction of new subjects that it was soon lengthened to four years and subdivided into numerous parallel courses. Entirely new types of high schools too, were created such as commercial, agricultural and manual arts, and out of this evolution came the so called cosmopolitan high school offering instruction in many different types of general and special training. With the enactment by congress of the Smith-Hughes Vocational Education bill (1917), giving aid to the states for agricultural, home economics and industrial education, a vast system of vocational education, secondary and local in character but national in scope and purpose, began to be developed. Thus the American high school, as the result of a century of progress and evolution, developed into a comprehensive system of secondary education which an increasingly large proportion of the youth of the land, of both sexes, attended. Day schools, night schools and continuation schools all formed a part of this secondary school system.

University Expansion.—Accompanying the expansion of the high school came a similar development of college and university training. From about 1885, when the state universities began to turn their attention to serving and advancing the welfare of the state, both university attendance and university revenues advanced by leaps and bounds. During the same period a number of new and important endowed university creations also made their influence felt. Coincident with the rapid increase in students, schools and courses, came the greatest number and amount of gifts of money ever made to aid higher education in any land. The states, too, put millions of dollars into the equipment and maintenance of these higher institutions, believing in them as the creators of advanced public opinion and as training schools for the future leaders of the state. (See also UNIVERSITIES.)

Educational Reorganization.—Beginning about 1910 an important reorganization of the upper years of the public school systems in the United States took place. Instead of an educational organization consisting of eight years of elementary school and four years of secondary school, there was evolved a six-year elementary school dealing with the fundamental tools and skills, a three-year junior high school with a greatly enriched course of study designed to meet the special biological and psychological and social needs of young people in their teens, and a three-year senior high school planned for later adolescents. This substituted a 6-3-3 type of educational organization for the former 8-4 type. Few fundamental changes in educational organization were accepted more rapidly than this.

Another administrative reorganization was the extension upward of the public school system to include the 13th and 14th years of school life—the freshman and sophomore years of the traditional college. A number of U S cities added these years to their public school system by organizing what came to be known as a junior college, thus making their public school system a 6-3-3-2 school system.

Lateral Expansion of the School.—Along with the vertical expansion of the public school system there was also a vast lateral expansion of the school. Especially from about 1900 was this a marked feature of U S educational work. Pedagogical and intelligence testing revealed the need for differentiated instruction, and this was met by the institution of flexible plans for grading and promotion and the organization of ungraded and special-type classes to meet many varying needs. Classes were organized for overage, non English speaking, deaf, blind, crippled,

tubercular, anemic, speech defective, subnormals and other types of children in need of special attention and care. The handling of disciplinary cases also called for the organization of the ungraded room, the opportunity school and the parental school. Industrial classes, trade schools and special vocational and home-making schools were instituted for other children who could not profit by the bookwork of the ordinary school. Adult instruction experienced a marked development. Another aspect of the lateral expansion of the school was the attention given to problems of health, physical welfare, playground work, nutrition, abnormalities, child care, preventive hygiene and parental guidance and in infant welfare. The school physician, the school nurse, the visiting teacher and the compulsory attendance officer all combined in service to the child not making proper progress in the regular school. The school guidance counselor was also added to help guide boys and girls into their tasks, and other advisers (detins) to help the youth of both sexes in handling their personal problems. Education in America thus took on many new functions of a personal and public welfare character. (E. P. Co. 3.)

Federal Aid—The temporary dislocation of the U. S. educational system during the depression of the 1930s and the pressing need of trained civilian manpower led to increased financial aid from the federal government and to the assumption of extensive educational functions by almost every department of government. This development was particularly marked in connection with the emergency programs which began in 1933.

Funds amounting to a total of about \$2,000,000 were provided to keep schools open in many areas. The Federal Emergency Administration of Public Works (PWA) made grants for the construction and repair of educational buildings which up to 1937 had amounted to a total of \$263,000,000, supplemented by loans of \$83,000,000. Under the Works Progress (later Work Projects) Administration (WPA) \$250,000,000 was spent for the repair of old buildings and the construction of new buildings for educational and community recreational activities. The same administration under its emergency education program hired about 44,000 unemployed teachers to give various types of part-time education which enrolled more than 1,700,000 persons. In the schools books were repaired, libraries maintained and lunches provided in addition to numerous other useful activities. A notable contribution was also made by WPA in the support given for the establishment of nearly 1,500 nursery schools during the depression years and an increasing number during World War II to take care of children of working mothers in defense areas.

In 1934 a program of student aid was begun under the Works Progress Administration and transferred in 1935 to the National Youth Administration (NYA). Aid was given under this program to students who otherwise could not remain in high school or college in return for part-time employment in the school or on the campus or on work of value to the community. A year before the student aid program was adopted the Civilian Conservation Corps (CCC) was established as a form of work relief which combined work with other forms of educational experiences at the elementary, secondary and even college levels. At the same time the other activities of the federal government in education were continued with increased grants for instruction and research in land grant colleges, agricultural and home economics extension work in rural areas and for vocational education and vocational rehabilitation.

World War II imposed new responsibilities, the major burden of which was assumed by the federal government to promote education for defense. In addition to the training of army and navy personnel in colleges, an extensive program for the training of workers in industry and agriculture was undertaken in 1942 under the direction of the U. S. Office of Education and continued until June 1945. During this period provision was made for the training of 13,000,000 students in high schools, special courses, colleges and universities. Of this number, 1,500,000 men and women were trained in colleges and universities, some under the Engineering Science and Management War Training Program (ESMWP), some in special courses, others in co-operation with industrial concerns. Training for industry was provided for 8,000,000 students

in 2,500 schools and for food production for 2,500,000 in 15,000 farm communities. Under the Lanham act, 1941-45, child care centres were established for children of mothers engaged in war industries. Funds were also provided by the federal government for maternal and child health, for welfare services for dependent and delinquent children and for medical care for crippled and handicapped children.

Despite the fact that the federal government during the depression and the years of World War II embarked on an extensive educational program in addition to the continuing program of supporting education proposals for the development of a policy of federal aid to correct inequalities in the provision of educational opportunity continued to meet with resistance. The opposition came in the main from groups which insisted on the tradition of states' rights and feared that federal aid might be followed by federal control in education. While some of the funds were channelled through the state and local educational agencies to be administered by them under federal supervision of a general nature, others were administered directly by federal bureaus and agencies.

The crisis came to a head in 1941 with mounting criticism of the tendency on the part of federal agencies to administer directly the educational services provided under the programs for the Civilian Conservation Corps and the National Youth Administration. As a consequence of this criticism, and also because of the entrance of the country into World War II, which demanded other methods for training youth, the CCC was discontinued in 1942 and the NYA in 1943.

Secondary Education—In no branch of education did greater uncertainty and unrest prevail in the second quarter of the 20th century than at the secondary level. The problems represented the accumulation of difficulties which had begun to manifest themselves at the beginning of the century. An education devoted primarily, but in U. S. history not wholly, to preparation for college entrance and based on an academic curriculum became the object of criticism and attack with the rapid increase in the number of boys and girls in the high schools for whom the academic subjects appeared to be unsuitable. The enrollments in public high schools rose from 2,494,676 in 1920 to 4,799,867 in 1930, by 1935 they had increased to 5,974,537 and five years later to 7,113,283. By 1942-43 the enrollments had dropped by nearly 1,000,000 to 6,122,066, partly because of war conditions and partly because of the reduced birth rate during the depression years. They dropped further to 5,553,520 in 1944 but increased later, however, to about 6,000,000 in the early 1950s.

The curriculum was broadened but mainly by the addition of new subjects more practical in character and without a general and integrated reorganization of the program. The social and economic changes which took place in the period between World Wars I and II, the increasing unemployability and unemployment of youth, the shortage of teachers and the demands of the war years tended to focus attention on education and particularly on secondary education. The NYA brought out the importance of providing aid to students if they were to be enabled to continue their education, while both the NYA and the CCC experiments emphasized the value of work experience in the preparation of youth for adult life.

From another point of view the demands of the war revealed certain defects in the quality of high school and college education. Difficulties were encountered in recruiting military or civilian personnel fit to take on the mastery of the languages which were included in the curriculum of both high schools and colleges. Before the entrance of the country into the war, Adm. Chester W. Nimitz drew attention to the fact that, owing to the lack of candidates for the naval officers' training corps and for commissions who were suitably prepared in mathematics, the passing mark in the examinations had to be lowered. Finally, the results of a test on U. S. history given by the *New York Times* to 7,000 students in 36 colleges and universities indicated that there was not only a lack of knowledge, but widespread misinformation about the subject. Although considerable controversy was aroused about the validity of the test, there were many who showed concern about the results of the investigation. Several states—Illinois and New

Jersey for example—enacted laws requiring the teaching of U S history in all publicly supported institutions or for a specific number of years in high schools

The criticisms of the work of the high schools from the point of view of the organization of subject matter were, however, either discounted or ignored, and the trend was set in another direction. In 1940 the American Youth commission appointed a special committee to report on needed changes in the curriculum of secondary schools. The committee in its report based its recommendations on the change in the character of the high school population, the different social origins and occupational interests of the students, the need of a program to meet the interests of the large majority and the fact that only a minority would continue education beyond the high school. It pointed out that many pupils in high schools had reading ability of the fifth or even the fourth grade level, that many who were slow learners lacked either interest in subjects found in the prevalent programs or proper motivation for study. The committee concluded that the high school curriculum was generally inappropriate, that the conventional subjects—English, mathematics, natural sciences and foreign languages—needed to be re-examined, with less emphasis on the traditionally academic, and better adaptation to the interests and abilities of the students. It was recommended that the program of secondary education should concentrate on English, social studies and work experience.

This report was followed in 1944 by a more extensive report on *Education for All American Youth*, prepared and published by the Educational Policies commission of the National Education association. Purporting to be a description of secondary education as it might be conceived to be 20 years later, the report was based on the assumption that the prewar pattern of education was "shattered beyond repair," that "the end of the war was the end of an epoch to which there could be no return in education or in any other aspect of life," and that the tremendous pressure of the traditional educational program stood in the way of reform. The types of programs that should be developed were illustrated by accounts of two hypothetical experiments—one in a rural and one in an urban high school, in courses extended by two years to include community institutes or junior colleges as a normal part of the reorganized system of education. The traditional arrangement of the program by subjects would be replaced by "curriculum areas." Thus, in the urban high school the curriculum areas would consist of "common learnings" ("to help students grow in competence as citizens of the community and the nation, in understanding of economic processes and of their roles as producers and consumers, in co operative living in family, school and community, in appreciation of literature and the arts, and in the use of the English language"), health and physical education, science, emphasizing methods, principles and facts needed by all students, vocational preparation including also preparation for college entrance, and the development of individual interests—vocational, cultural or intellectual. Corresponding programs would be developed for rural high schools. The conventional subjects would appear in the new courses insofar as they would be needed to meet the common needs of youth, but they would be found "in unaccustomed settings" among the "common learnings."

Higher Education during World War II—The crises of World War II seriously affected the status and progress of higher education in the United States. In 1936 there had been a slight increase over the previous year of 6% in the enrolments in colleges and universities and of 9% in junior colleges. This increase was maintained until the outbreak of World War II. A more serious problem than that of enrolments, however, was the reduction in the income from investments of endowments and in the number of gifts. The increased enrolments were due largely to the grant of student aid under the National Youth administration. The shrinkage of income meant, on the one hand, curtailment of staffs, particularly among the younger members, despite the larger number of graduate students and Ph D's available, and on the other, made it impossible to increase salaries and in many institutions compelled a reduction. These conditions led to proposals for federal aid, without leading, however, to definite action.

The outbreak of the war in Europe had an immediate effect on enrolments in institutions of higher education as a result of uncertainty in the political situation, the increased opportunities for employment and expectation of the draft. Enrolments in 1940 were practically the same as in 1939, in 1941-42 there was a definite decrease of nearly 9% as compared with 1940-41, the heaviest losses took place in tax supported institutions and in independent teachers colleges. The distribution of students in the various fields of study showed a marked difference, the medical schools had the largest enrolments on record and engineering schools and scientific departments generally were attended by larger numbers, law schools were the worst hit by reduction in enrolments. In 1943-44 total enrolments were 1,120,300 or 18% less than in 1939.

The uncertainty as to the future of U S higher education which had begun during the depression years became still more aggravated after Pearl Harbor. For nearly a year there was no clear statement of policy from the government either on the status of students of draft age or on the use that might be made of colleges and universities for the war effort. The leadership in higher education was assumed by the American Council on Education, established during World War I to serve as a co ordinating agency in this field. Two weeks after Pearl Harbor the Planning and Executive board of the council recommended the adoption of accelerated programs by colleges and universities and emphasized the importance of continued education for able students to meet the future demands for physicians, dentists, engineers and other professional workers.

The situation became clearer in 1943, then the war and navy departments entered into contracts with 479 institutions to give instruction in some designated branch of the armed services—engineering, aviation cadets, WACs, basic training, personnel psychology, language training, premedical studies, meteorology, chemical warfare, basic medical sciences and medical, dental and veterinary training. The candidates for the army specialized training programs (ASTP) were enlisted men selected by classification and personnel officers. The basic program included English, history, mathematics, physics and chemistry in addition to specialized studies. On completing the courses students were recommended for admission to officer candidate schools or were assigned for immediate service. A similar system was established by the navy in the V 12 courses. At the same time a more liberal Selective Service policy was adopted for students in preprofessional and professional courses, such as agriculture, forestry, pharmacy, optometry and in internships, provided they received certificates of competence from the institution attended and showed promise of completing their studies successfully by July 1, 1945. In Feb 1944 the war department announced that the ASTP would be partially discontinued, only 35,000 out of 145,000 students were retained in medicine, dentistry and engineering, and more than 300 institutions were affected. FRANCE

Early Stages of Public Education—No historical sketch of French education can ignore the great Catholic religious educator of the 18th century, Jean Baptiste de la Salle, the founder of *Les Frères de la doctrine chrétienne*, commonly known as the "Christian Brothers." The brothers were not merely pioneers of elementary education, they may also be regarded as the originators of higher primary instruction. Under the restoration they upheld the method of simultaneous teaching against the partisans of the mutual (or monitorial) method, successfully demonstrating the superiority of the trained teacher.

The Revolution—The constitution of 1791 decreed that primary instruction should be compulsory and gratuitous. In this as in much else the Revolution was powerless to do more than enunciate general principles which it left for later generations, in

the present instance after the lapse of nearly a century, to carry into effect. True to its theories of individualistic liberty, the Revolution admitted liberty to teaching. Napoleon on the other hand by the law of 1806 centralized all forms of education in one official teaching body under the name of the Imperial university, thus securing a monopoly of teaching to the state.

Under the Restoration education fell inevitably under the control of the church but under the Liberal monarchy François Guizot in 1833 passed a law which laid the foundations of modern primary instruction, obliging the communes to maintain schools and pay the teachers. It is also to the credit of Guizot as an educational reformer that he perceived the necessity for the higher primary schools which he founded were unfortunately suppressed by the *Loi Falloux*, then restoration constituted one of the great positive services rendered by the third republic to the cause of popular education.

Loi Falloux.—The *Loi Falloux* of 1850, passed by the second republic under the influence of the prince president, is chiefly memorable for its restoration of the liberty of teaching, which in Catholic country means in effect free scope for priestly schools. This law also made provision for separate communal schools for girls, for adult classes, and for the technical instruction of apprentices. In 1854 France was divided for purposes of educational administration into 16 académies, each administered by a rector with an academy inspector under him for each department.

The ministry of the well known educationist, M. Duruy (1859-69) corresponding to the period of the Liberal empire, rendered primary schools for girls obligatory in communes of more than 500 inhabitants. Duruy also provided for the introduction of gratuitous instruction at the option of the commune.

Organization by the State.—The task of educational reform imposed itself upon the republic by a twofold necessity. The wars of 1866 and 1870 were victories for the Prussian schoolmaster and aroused western Europe to the national importance of popular education. For France the reform of popular education was an essential part of the work of national restoration. For the republic, too, menaced by older and hostile traditions, the creation of a national system of education inspired by its own spirit was an essential condition of the permanence and security of its government and the social ideals of which that government was the expression. Hence the energy with which the republican state addressed itself to the organization of primary instruction, "obligatory gratuitous, secular."

By the law of June 1, 1878, there was imposed upon the communes the obligation of acquiring their school buildings, and as a grant in aid a sum of £2,400,000 was set aside for this purpose by the state. In 1879 a law was passed compelling every department to maintain a training college for male and female teachers respectively. The two higher normal schools of Fontenay and St Cloud were also founded to supply the training colleges with professors. During the same period, among other certificates or professional diplomas, there were established the *certificat d'aptitude pédagogique*, which qualified probationer-teachers (*stagiaires*) for appointment as teachers in full standing (*titulaires*), and the *certificat d'aptitude* for primary inspectors and heads of normal schools. The law of June 16, 1881, rendered obligatory for all teachers whether public or private the *brevet de capacité*. It was, however, impracticable to carry this law into immediate effect through conditions hard imposed.

The laws making primary education gratuitous compulsory and secular are indissolubly associated with the name of Jules Ferry. The law of June 16, 1881, abolished fees in all primary schools and training colleges, the law of 1882 established compulsory attendance, and finally the law of Oct. 30, 1886, enacted that none but lay persons should teach in the public schools, and abolished in those schools all distinctly religious teaching. In the boys' schools members of religious communities were to be displaced within five years but in girls' schools the religious might remain till death or resignation. The law of Aug. 9, 1936, made education compulsory to the age of 14.

Moral Instruction.—Religious teaching was replaced in the

state schools under the Ferry law by moral instruction according to official curricula. In regard to the character of this instruction it would seem to have shifted from a Kantian mainly to a sociological basis. Roman Catholic opinion was as essentially or necessarily antireligious, and plainly there was no inherent reason why the neutrality should not be a real neutrality, but with the relations between the Catholic Church and modern thought in France the influence of the nominalist teachers was in fact to be antireligious and moreover no system of independent moral doctrine, whether based upon *a priori* or inductive reasoning could be acceptable to the Roman Catholic Church. In whatever degree the blame might be rightly apportionable between church and state, the fact is that the two found themselves in acute conflict. It may be that the mischief would have been mitigated had more moderate counsels prevailed at the time of the Ferry law, and had the church been willing to accept (as the republic might have been willing to concede) right of entry for the clergy into the schools. In the meantime the religious difficulty in the schools divided the nation into two hostile camps (*les deux Frances*, as a Swiss Protestant writer put it) in the shape of the state secular schools on the one side and the private religious schools on the other.

Secondary Education.—In proceeding to sketch the French system of higher primary and secondary schools, it may be observed that European systems of higher education were generally framed upon the view that secondary education is a training complete in itself from the preparatory stage to the university, with aims and ideals of general culture which differentiate it radically and at the very outset from education of the elementary type. On the other hand, in the United States, the view prevailed that the secondary school must be complementary to the elementary school, in which even the elite must receive their preparatory or elementary training. At any rate, down to the reform of 1902, which will presently be explained, the French system could be regarded as a typical and even extreme example of the European type, little consistent as this might seem to be with the broader principles of democracy. A further breach was made in the theory by an augmentation in the number of scholarships following World War I and by an experiment to amalgamate in country districts small secondary day and higher finishing schools.

Higher Primary Schools.—The aim of the *écoles primaires supérieures* was to fill the void which must otherwise exist for those needing a higher education than the primary school could give. Throughout the organization of primary education the French kept steadily in view the danger of creating an intellectual proletariat. *Nous poursuivons la culture générale du caractère et de l'esprit, mais nous cherchons en même temps à orienter l'enfant vers la vie pratique*, says an official report. The aim of the higher primary school was to continue education in this spirit up to the age of 16 so as to prepare the scholar to take an honourable place in the higher ranks of skilled industry. In 1942 the *écoles primaires supérieures* were replaced by the *collèges modernes* (modern schools).

Lycées, Classical Schools and Modern Schools.—French secondary education for boys is given in the lycées, which are first grade schools maintained and controlled by the state, in the so-called classical schools maintained by the municipalities, and in the *collèges modernes* mentioned above.

Secondary Education for Girls.—The foundation of secondary schools for girls was in its way one of the most notable achievements of the third republic. It was inaugurated by the law of Dec. 22, 1890, called after its author, *La Loi Camille Sée*. At first the curricula were different from those of the boys, and the course of study was only five years. There were no ancient languages and mathematics were not carried to so high a pitch as in the boys' lycées. After 1942 there were three types of establishments the same as for boys (see above).

Private Secondary Schools.—Until the passing of the Waldeck-Rousseau law prohibiting religious associations, the number of pupils in the state secondary schools and the private secondary schools were approximately equal the great majority of the latter schools being in the hands of the religious orders. The Waldeck-

Rousseau Act was passed on July 1, 1901, and in 1904, under M Combes, the religious schools were suppressed by law. Some man aged none the less to maintain their ground. Under the heading of the private secondary schools should be mentioned Honoris causa, l'école des Roches founded by M Demolins (author of *Quoi tient la supériorité des Anglo-Saxons*) and Le Collège de Normandie, founded by M Duhamel, a former French master at Harrow school, England. The Waldeck Rousseau act also caused a temporary decrease in the number of pupils in the religious elementary schools.

Secondary School Curriculum.—In 1902 reforms were made in the curriculum. Article 1 of the decree of May 31, 1902, coordinated with primary education so as to constitute a continuation of a course of primary studies of a normal duration of four years. The decree went on to provide for a full course of secondary studies of seven years' duration, divided into two cycles of four and three years respectively. In the first cycle the scholar had two options. In section 1 Latin was obligatory and Greek optional from the beginning of the third year (*classe IV*). In section 2 there was no Latin. At the end of the first cycle the state granted a *certificat d'études secondaires du premier degré*. In the second cycle one of four courses might be taken: section 1 with Latin and Greek continued the old classical education, section 2 with Latin and modern languages corresponded to the German *Realgymnasium*, section 3 with Latin and science, and section 4 with modern languages and science to the *Oberrealschule*. The *baccalauréat*, or secondary school-leaving examination, conducted by the university, was adapted to all the courses on the principle that courses of study of equal length, whether classical or modern, literary or scientific, were entitled to equal advantages.

In 1903 the minister of public instruction, M Léon Bérard, decided to abolish the four alternative sections and make Latin compulsory for four years and Greek for two, for all secondary pupils. The course in science was to be the same for all pupils, and it was only in the year before the *baccalauréat* that the pupil could choose between classics and a modern course. The Bérard reforms considerably lightened the timetable by cutting down, above all, the mathematics, and simplified the overelaborate choice of studies, but the proposal of classics for all roused the most violent opposition. A change of government made it easy for M Herriot—the new minister of public instruction—to re-establish the modern Latinless course, but the others were not revived. Henceforth the pupils had a choice between classics and a modern course, but whichever they chose, for two-thirds of the timetable in such subjects as French, history, geography, etc., they were taken together, though the system met with a good deal of criticism.

Technical Schools.—A certain number of technical schools, formerly under the ministry of commerce, were brought under dependence of the ministry of public instruction. They included six national professional schools, six *écoles nationales d'arts et métiers*, higher schools of commerce and *écoles pratiques de commerce et d'industrie*, as well as commercial and technical courses. There was also a network of institutions and schools run by the ministry of agriculture, from the national agricultural institute of Paris, and the national schools of agriculture at Montpellier and Rennes, down to the *fermes-écoles* and the *écoles pratiques d'agriculture*. (C Br, X)

GERMANY

Latin Schools.—Martin Luther's famous letter to the German municipalities in 1524 urged upon them the duty of providing schools and upon parents the duty of sending their children to school. An attempt to carry this into effect was made by the electoral government of Saxony which issued in 1528 an ordinance, drawn up by Melancthon, providing for the establishment in every town and village of Latin schools, for the Protestant reformers were solidly in favour of classical education. It is, therefore, all the more remarkable that the ordinance issued by the elector of Württemberg in 1559 represented the first systematic attempt to provide both elementary and higher education directing the establishment of elementary schools throughout the country and of Latin schools (or *Particularschulen*) in every con-

siderable centre of population. These promising beginnings were, however, brought to nought in the troublous times of the Thirty Years' War, and by the desolation and national decadence which that calamity brought in its train. The permanent and positive value of Luther's pronouncement of 1524 lies not so much in its direct effects as in the hallowed associations which it established for Protestant Germany between the national religion and the educational duties of the individual and the state. Thus, doubtless, was created that healthy public opinion which rendered the principle of compulsory school attendance easy of acceptance in Prussia at a much earlier date than in England. State interference in education was almost coincident with the rise of the Prussian state. In 1717 Frederick William I ordered all children to attend school where schools existed. This was followed in 1736 by edicts for the establishment of schools in certain provinces and by a royal grant of 50,000 thalers for that purpose in the following year. In 1763 the *Landschulreglement* of Frederick the Great laid down the broad lines upon which the Prussian state thereafter proceeded, asserting the principle of compulsory school attendance.

Karl Wilhelm von Humboldt.—It was not until after the disaster of Jena (1806) that any effective reorganization of the educational system was carried out. One of the first acts of the minister Baron von Stein in 1807 was to abolish the semiclerical *Oberschulkollegium*, and to place education under the ministry of the interior with Karl Wilhelm von Humboldt (*q v*) at the head of a special section. Humboldt's policy in secondary education was a compromise between the narrow philological pedantry of the old Latin schools and the large demands of the new humanism of the period. The measure introduced by Humboldt in 1810 for the state examination and certification of teachers asserted the then common practice of permitting unqualified theological students to teach in the schools, and at once raised the teaching profession to a high level of dignity and efficiency which of itself sufficed to place Prussia in the forefront of educational progress. It was due also to the initiative of Humboldt that the methods of Pestalozzi were introduced into the teachers' seminaries, through them to vitalize the elementary schools. To the period of the national struggle belong the revival, 1812, of the *Abiturientenexamen* (the school-leaving examination) which had fallen into abeyance, and the institution about the same time of the local authorities called *Schulvorstände* for the country and *Schuldeputatsen* for the towns.

Though the period which succeeded the peace of 1815 was one of political reaction, the work of administrative organization was carried on by defining the duties of the *Provinzial-Schul-Kollegium* and the *Regierung*. In 1834 an important development was given to secondary education by making it necessary for candidates for the learned professions, as well as for the civil service and for university studies, to pass the leaving examination of the *Gymnasien*. Thus through the leaving examination the state held the key to the liberal careers, and was thereby able to impose its own standard upon all secondary schools.

Administrative Machinery.—In connection with the *Kulturkampf*, or struggle between the state and the Roman Catholic Church, the *Schulaufsichtsgesetz* of 1872 reasserted the absolute right of the state alone to the supervision of the schools. Nevertheless the Prussian system remained both for Catholics and Protestants essentially denominational. All schools, whether elementary or secondary, were Evangelical, Catholic, Jewish or mixed. In the elementary sphere, in particular, recourse was only had to the mixed school (*Simultanschule* or *paritätische Schule*), where the creeds were so intermingled that a confessional school was impracticable. In all cases the teachers were appointed with reference to religious faith, religious instruction was given in school hours and inspected by the clergy. Under the ministerium in Berlin stood the *Provinzial-Schul-Kollegium*, the chairman of which was the *Ober-Präsident* of the province, composed of four or five *Räte* or councillors, generally selected from the directors of *Gymnasien*. This body was concerned mainly with higher education.

Each province was divided for purposes of general administration into two *Regierungs* or governments, and in each gov-

ernment there was a section consisting of three or four *Schulräte*, which controlled the elementary schools. This council was usually recruited from the ranks of directors of training colleges and from the inspectors. The *Regierung* was divided into *Kreise* or districts, and in each district an administrative officer, called the *Landrat*, represented the government. The *Landrat* was concerned with the provision and repair of elementary school buildings, for internal organization, the elementary schools were under the *Kreisschulinspektor*.

In the Protestant districts the inspectors often were Evangelical clergymen, but later inspectors with pedagogical qualifications and the status of full government officials were appointed. For every school there was a local inspector (*Ortschulinspektor*), usually the clergyman of the parish, who discharged the duties of local manager and correspondent.

The official classification or grading according to the type of curriculum of secondary schools in Prussia (and throughout Germany) was very precise. The following were the officially recognized types of the period: (I) Classical schools: (1) *Gymnasium*, with nine years' course; (2) *Progymnasium* with six years' course. (II) Modern schools: (1) with Latin (semiclassical)—(a) *Realgymnasium* (nine years' course), (b) *Realprogymnasium* (six years' course), (2) without Latin (nonclassical)—(a) *Oberrealschule* (nine years' course), (b) *Realschule* (six years' course).

The differentiation between the types was the result of a natural educational development corresponding with the economic changes which transformed Prussia from an agricultural to an industrial state. The classical schools long retained their social prestige and a definite educational advantage in that their pupils were alone admissible to the universities. From the foundation of the empire (1871) the history of secondary education was largely concerned with a struggle for a wider recognition of the work of the newer schools. The movement received a considerable impetus by the action of the emperor, who summoned a school conference in 1890, at which he criticised the *Gymnasien* as lacking a natural basis. "It is our duty to educate young men to become young Germans and not young Greeks or Romans." New timetables were framed in which the hours devoted to Latin were considerably reduced and no pupil could obtain a leaving certificate without a satisfactory mark in the mother tongue. The results satisfied neither party and the reform listed only a single school generation. In 1900, after a second conference, equality of privileges was granted to three types of schools, subject to certain reservations—the theological faculties continued to admit only students from classical schools, the pupils of the *Oberrealschule* were excluded by their lack of Latin from the medical faculties, but in so far as Latin was required for other studies, such as law or history, it could be acquired at the university itself.

Although the official programs were binding on the schools, their rigidity was not absolute, experiments were possible, but they were carefully supervised. It was thus that the modifications of the classical school program known as the Frankfurter system came into being, after a similar experiment had been tried at Altona. The chief innovation—and there the two schemes agreed—was the postponement of the beginning of Latin to *Untertertia* and the introduction of French as the first foreign language. This enabled parents to defer their decision as to the form of their son's education until he was about 12 years of age.

A further list of the willings of the authorities to sanction reasonable changes was seen in the permission accorded to certain schools to vary the course of study, in the late classes, as a preparation for the freedom of choice at the university.

Girls' Schools.—In Prussia, as elsewhere, the higher education of girls lagged far behind that of boys and received little attention from the State or municipality except so far as the services of women teachers were needed in the elementary schools. Thus it came about that in Prussia secondary schools for girls were dealt with administratively as part of the elementary school system. After the establishment of the empire a conference of directors and teachers of these schools was held at Weimar and put forth a reasoned plea for better organization and improved status. The advocates of reform, however, were not at unity in their aims,

some wished to lay stress on ethical, literary and aesthetic training, others on intellectual development, and claimed an equal share in all the culture of the age. But even in the schools the women fought an unequal battle, for all the heads and a large part of the staff were men usually academically trained. The women continually demanded a larger share of the work, and this was secured by the establishment of a new higher examination for women teachers. University study though not prescribed was in fact essential and yet the women had not the right of access to the university in Germany. They were allowed to take the *Abstinenzexamen*, for which private institutions prepared them, but their admission to the university rested with the professor.

Economic necessity and the growing strength of the women's movement at last brought the desired change. New programs were issued in 1908, organizing the girls' schools in two degrees: the *Lyceum*, a ten class institution for girls from 6 to 16, and an *Oberlyceum* of three classes of varying types, one of which might be a training department for teachers, another for home life. But apart from these normal courses, opportunity was given to girls to follow from their 12th or 13th year courses similar to those of the higher schools for boys. The form generally preferred was that of the *Realgymnasium*. At the same time a ministerial decree opened the German universities to women on the same terms as men.

Elementary Schools.—In no sphere of public activity did the revolution of 1918 cause more far reaching changes in Germany than in that of education. The ultimate aims which these innovations envisaged were clearly stated in the Weimar constitution, and led to a single system of national education. It was recognized that this goal could only be reached by gradual steps and the responsibility for educational administration was left with the federated states. The state ministers, however, had to observe the principles enunciated in the constitution and to conform to the federal laws enacted to secure the realization of the republic's ideals.

The elementary school, which under the old regime was a class-school, became a national institution, serving all and used by all. It had no rivals and private elementary schools were forbidden in those early years for which the common school exists. The *Einheitschule*, which the popular parties had demanded before World War I, became an accomplished fact, as far as the first four years of the course were concerned. As a concession, reluctantly granted, specially gifted children were allowed to complete the course in three years.

When the *Grundschule* (basic school) had been passed the child might be transferred to a secondary school, organized to lead on to the university, or he might go to the *Mittelschule*, if he wished to enter commerce or industry about the age of 16, or he might remain at the elementary school, if he had to enter on employment at the earliest possible age.

New Types of Secondary Schools.—After 1918 the interests of poor but gifted boys were well served. Two new types of schools catered to their particular needs. There was first the *Deutsche Oberschule*, in which, in harmony with the sentiment of the Weimar constitution, the emphasis was laid on the training of a national spirit, and German history, literature and art were all studied from this national standpoint, though foreign languages were not excluded. These schools replaced, to a large extent, the old institutions which prepared former elementary school pupils for admission to the training colleges for teachers of primary schools.

The other new type was the *Aufbauschule* ("built-on" or supplementary school). Its place in the educational scheme resembled the high school or the United States in that it only received pupils who had completed the primary school course.

(A. E. Tw., X.)

The Third Reich and After.—Under Adolf Hitler the formal organization of the elementary and secondary systems was not changed radically, but the content of education underwent a vast transformation to make it conform with national socialist ideology. Youth labor camps were established in which the educational keynote was nationalistic and utilitarian. Personnel of the schools

was transformed, studies were wrested from their proper position as independent forms of truth and knowledge, and indoctrination permeated the whole educational system. Wherever German influence extended prior to and during World War II, anti-Semitism followed, resulting in the expulsion of Jewish teachers. The traditional nine year course was reduced to eight, and potential nazi "leaders" were sent to *Adolf Hitzlerschulen*. The system introduced during the Weimar republic which placed teacher preparation on a university basis was discarded and replaced by one which was to recruit candidates at the age of 14 from a new type of higher primary school (*Hauptschule*) and train them in small institutions for five years. This represented a return to a system against which German teachers had been protesting for a century.

After World War II the German system again underwent a thorough overhauling in every *Land*, designed primarily to "de-nazify" the curricula and the teaching personnel. In soviet occupied east Germany, however, the system was naturally made to conform with Communist educational ideals (X)

EDUCATION, THE UNITED STATES OFFICE OF, established by congress in 1867 as an independent department of the government, officially changed in 1869 to an office in the department of the interior, in 1939 transferred by executive order to the Federal Security agency, is the principal agency of the United States government for educational research, statistics, surveys, investigations and demonstrations and for the promotion of the cause of education throughout the country. It has no administrative authority over the various state systems of education although it exercises some administrative functions in the disbursement of financial grants-in-aid appropriated by congress for colleges of agriculture and mechanic arts and for vocational education of less than college grade in agricultural, homemaking, trade and industrial, and distributive business occupations in the states, territories and the District of Columbia. The influence of the U.S. office of education upon school systems and school practices in the United States is chiefly brought about by publication of numerous monographs reporting results of statistical and other studies, by the convening of national and other conferences, and by consultative services rendered by its professional staff and field agents.

EDUCATIONAL ASSOCIATIONS Many educational and professional associations were formed after the middle of the 19th century, these did much to co-ordinate methods of education and to improve the professional standards of teachers.

UNITED STATES

Educational associations to advance the status of the profession and improve educational practices were formed in the middle of the 19th century under the leadership of such men as Horace Mann and Henry Barnard.

The federal government has no authority to require standard courses of study, teacher training, management, methods or finance as in those countries where education is directed by the central government, yet a U.S. system has grown up through the zeal of teachers who have overstepped state boundaries to join with their coworkers in conference and in educational investigation. The result has been that educational methods and standards, materials, processes and attitudes have become nearly uniform

throughout the states and territories of the union.

Educational organizations in the United States are local, state and national in scope. They may also be classified as general and special, according to their aims and purposes. There is scarcely a county of the United States which has not its organization and every city has from one to several. Each state and territory is organized. Local associations function in the solution of problems which concern their members in their local relationship. Their programs vary widely, but professional improvement, teacher welfare, social betterment and community service are common objectives. Most local associations are affiliated with the state associations.

The activities of state associations include conventions, publications, legislation, research, field service, public relations, teacher welfare, membership promotion, and co-operation with the national organization. All state associations and Alaska, the District of Columbia, Hawaii and Puerto Rico are affiliated with the National Education Association. In this connection the states co-operate in national projects, lend counsel on national policies, assist in the enlistment of members of the national association, and send official delegates to the national conventions.

The most influential educational organization in the United States, the National Education Association, was organized at Philadelphia, Pa., in 1857, under the name, The National Teachers' Association. The name was changed in 1870 to the National Educational Association, and in 1907, by act of the U.S. congress, the new charter was adopted designating the organization as the National Education Association of the United States. Its general purposes may be considered the objectives of many educational associations in America. "The purpose and object of the incorporation shall be to elevate the character, to advance the interests of the profession of teaching and to promote the cause of education in the United States." It includes the National Council of Education and the following departments: administrative women, adult education, art education, business education, classroom teachers, deans of women, educational research, elementary school principals, exceptional children, garden education, health, physical education and recreation, higher education, home economics, industrial arts, journalism directors, kindergarten, primary education, lip reading, music educators, rural education, school administrators, science teachers, secondary school principals, secondary teachers, social studies, speech teachers, supervision and curriculum development, teachers colleges, visual instruction, vocational education. New departments may be created and old ones discontinued or reorganized.

The representative assembly was created in 1921. In it state and local educational associations may be represented according to the number of their members who belong to the national body. The representatives take part in business sessions and in establishing the general policy. Under this reorganization, the association undertook to carry its influence and support to every teacher in the United States. The membership was extended from 8,557 in 1918 to more than 450,000 by the early 1950s.

The National Education Association is concerned with promoting teacher welfare, through the establishment of retirement systems for teachers, the assurance of tenure of position, and increased salaries. It stimulates beneficial legislation, research, and the general advancement of learning and culture. It has sponsored many forward movements in education and its publications give wide distribution to advances in educational procedure. It called the first World Conference on Education in San Francisco, Calif., in 1923, which resulted in the organization of the World Federation of Education associations.

There are many national organizations usually representing special interests. The American Council on Education, supported by associations, universities, secondary schools, state and local school systems, promotes many phases of U.S. education through co-operative action by institutions and it undertakes activities which will contribute to that end. The American Education Fellowship, formerly known as the Progressive Education Association, with a membership of about 9,000, publishes information about progressive educational principles and promotes experi-

and technical schools, the National Association of Head Teachers and the National Federation of Class Teachers. The two latter organizations include a large number of teachers in primary and central schools who are employed mainly in the principal urban centres of the country and are usually members of the union. Both bodies hold annual conferences at which educational and professional policies are formulated generally in harmony with those proposed by the National Union of Teachers. Most of these bodies make provision to co-operate with one another, and relations between teacher groups and local education authorities are on a very friendly basis, the change in attitude dating from the establishment of national committees to settle the question of scales of salaries for teachers. EDUCATIONAL PSYCHOLOGY *see* PSYCHOLOGY

EDUCATION IN ANIMALS concerns special influences which guide or control learning. Such influences may arise from ordinary experiences in the characteristic environment, from experiences with other animals, or through human guidance.

Education through ordinary experience is typified by the manner in which many young vertebrate animals modify their inborn snapping responses to small moving objects. At first the young chick pecks at both edible and inedible objects in motion, but after certain kinds of objects, e.g., hairy caterpillars, have been rejected repeatedly in response to their harsh effect in the mouth, these may be avoided in advance while others of different visual appearance are snapped up.

Education through the activities of other animals may occur incidentally, or through individual relationships meriting the term "tutoring." Often young mammals are weaned forcibly and thereby stimulated to acquire adult feeding habits, evidently more because physiological changes in the mother cause her to reject their advances than because she has a "teaching" attitude. In birds, parental behaviour frequently influences the appearance of adult behaviour in the young, as when fledgling birds of prey are at first given pieces of flesh and finally intact prey which they must handle independently, or when early flight is stimulated by pulling or forcing the young from the nest. In the higher mammals, situations in which one individual directly stimulates and guides learning in another are not uncommon. For example, a mother

monkey may release herself and back away from her infant thereby impelling it to follow independently. As another instance, in laboratory experiments one chimpanzee, in a joint rope-pulling test, retroussees its lagging partner by means of an identifiable gesture—a series of gentle taps with one hand. It must be remembered that an untrained animal profits only in a very general way from seeing another perform, unless the essential parts of the act have been learned previously. An untrained dog which sees another open a door by twisting the knob with his paws is not thereby enabled to duplicate the act, although when tested alone he may be more persistent in his attacks on the door and perhaps work more around the knob than would otherwise be the case.

Education through human guidance in its simplest form, the "conditioned response," requires as basis a response which the animal makes at the outset to some definite excitatory stimulus. For example, to teach a dog to lie down on command one begins by using the hands gently to force lying down, each time presenting the new stimulus ("lie down") until after many repetitions the words alone are sufficient. Similarly in circus training the basic responses (e.g., sitting still) essential for complicated training are fixed to particular stimulus cues through a conditioned response procedure. However, for highly skilled acts a complex routine of special training is necessary, a process in which appropriate techniques are used to emphasize each step of the serial act and to exclude undesired acts. This holds both for the training of domestic animals and for less ordinary processes such as educating elephants to dance or dogs to lead the blind.

Obviously, the critical limits of animal educability vary in different animal forms particularly in dependence upon the elaboration of cerebral cortex in the brain. The cortex of a rodent such as the rat is inferior to that of a carnivore such as the dog, and the rat is found correspondingly inferior in learning complex tasks. Furthermore, brain operations reducing the amount of cerebral cortex lower the educability of given individuals. Once the potentialities and capacities of the given animal for new behaviour are known, established principles of learning may be utilized to devise a suitable training program. (See PSYCHOLOGY, COMPARATIVE.) (T C S.)
